Lecture - 28
Constrained Optimization - II

Hello friends, welcome to lecture series on Essential Mathematics for Machine Learning. In the last lecture we have seen that if we have a if we are having a Constrained Optimization problem in which we have to optimize a function subject to certain set of conditions or constraints, then that problem is our quadratic programming problem if the objective function is quadratic and all constraints are linear. That will be a convex programming problem if objective function is convex and all constraints are convex.

And we have solved few problems based on this also in the previous lecture. In this lecture we will see that if a general non-linear problem is given to you then how we can solve that problem. If it is a convex programming problem? Ok.

(Refer Slide Time: 01:16)

Constrained Optimization Problem

The general form of a constrained optimization is given as:

$$\begin{aligned} \text{(P2) Min } & f(x) \\ \text{s/t } & g_i(x) \leq 0; \quad i = 1, 2, \dots, m. \end{aligned}$$

where f and $g_i(\forall i) : \mathbb{R}^n \rightarrow \mathbb{R}$ are defined and continuously differentiable functions.

The slide features a blue header and footer. The footer contains logos for institutions and a small number '2' in the bottom right corner.

So, this is the general constrained optimization problem which we have already discussed, we in which we have to minimize a function f which is objective functions subject to $g_i(x) \leq 0$ i from 1 to m . So, there are m number of constraints ok.

So, here we are assuming that f and g_i , for all i are defined and continuously differentiable functions ok.

(Refer Slide Time: 01:39)

Necessary Condition

Let \bar{x} be a local min point of the problem at which basic constraint qualification holds. Then there exist multipliers (called KKT-multipliers) $\bar{\lambda}_i, i = 1, 2, \dots, m$ such that the following conditions hold:

- 1 $\nabla f(\bar{x}) + \sum_{i=1}^m \bar{\lambda}_i \nabla g_i(\bar{x}) = 0,$
- 2 $g_i(\bar{x}) \leq 0, i = 1, 2, \dots, m,$
- 3 $\bar{\lambda}_i g_i(\bar{x}) = 0, i = 1, 2, \dots, m,$
- 4 $\bar{\lambda}_i \geq 0$ for all i .

These conditions are called KKT-conditions.

Now the necessary condition. The necessary condition means that suppose a point \bar{x} , suppose \bar{x} is a point which is feasible. Feasible means satisfy all the constraints and is a local optimal point for this problem P 2. Then what are the conditions that \bar{x} will satisfy? So, those conditions are called necessary conditions ok. And here these conditions are called Karush Kuhn Tucker conditions KKT conditions ok. And a point which satisfies all these conditions is called KKT point.

So, what is a theorem let us read out the statement. Let \bar{x} be a local minimum point of the problem P 2 at which the basic constraint qualification holds. What do you mean by basic constraint qualification? Basically these are the additional requirements which are required in the problem, so that the multiplier corresponding to the objective function is nonzero ok.

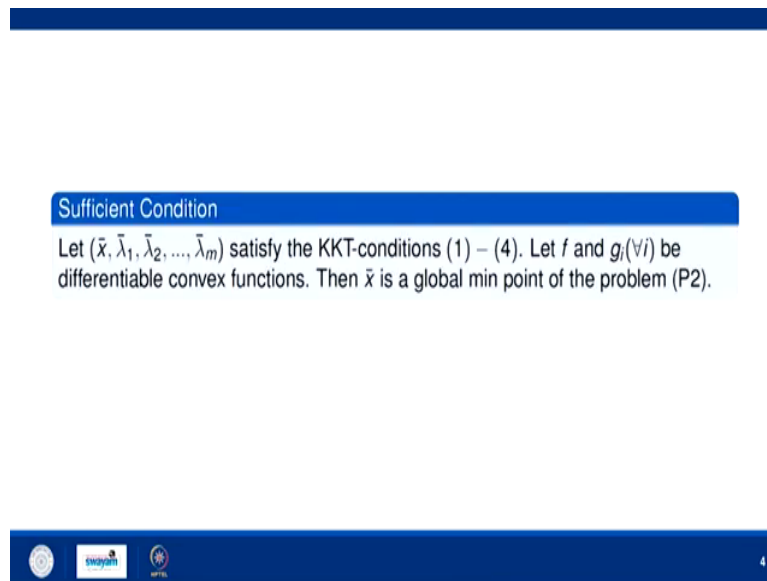

We want to multiplier. Here it is one. This one is coming only because we are applied some constraint qualification on the problem P 2. So, basically constraint qualification means that these are the additional requirement on the problem P 2, so that the Lagrange multiplier corresponding to the objective function is nonzero ok. So, holds.

Then there exist multipliers also called KKT multipliers. KKT means Karush Kuhn Tucker multipliers, λ_i for i from 1 to m such that the following conditions hold. So, these are the following conditions which must be hold and these conditions are called KKT conditions.

So, if \bar{x} is a local minimum point of this problem P 2 of this problem P 2 then these conditions hold, but these conditions are only necessary condition, these may not be sufficient. So, what the additional requirement?

What is the additional assumptions which must be required on f or g_i 's, so that these condition becomes sufficient. Sufficient means, that if you solve these conditions, if you solve a point, if you solve these inequalities and a point \bar{x} will satisfy these inequalities that will be a local optimal point of the problem P 2.

(Refer Slide Time: 04:18)

Sufficient Condition

Let $(\bar{x}, \bar{\lambda}_1, \bar{\lambda}_2, \dots, \bar{\lambda}_m)$ satisfy the KKT-conditions (1) – (4). Let f and $g_i(\forall i)$ be differentiable convex functions. Then \bar{x} is a global min point of the problem (P2).

4

So, those conditions are basically if we called as sufficient conditions and the additional assumption is, that f and g_i for all i must be a differentiable convex functions. So, basically is a problem P 2 is a convex programming problem then these conditions, then a point we satisfy these conditions will be a local optimal point or the problem P 2. That means, that these conditions become sufficient. Then \bar{x} is basically not only local, but it will be a global minimum point of the problem P 2.

(Refer Slide Time: 05:02)

$$\begin{array}{l}
 \bar{x} \\
 \text{To prove: } f(\bar{x}) \leq f(x) \text{ for all feasible point } x \text{ of (P2)} \\
 \text{KKT conditions,} \\
 (1) \quad \nabla f(\bar{x}) + \sum_{i=1}^m \bar{\lambda}_i \nabla g_i(\bar{x}) = 0 \\
 \Rightarrow \left(\nabla f(\bar{x}) + \sum_{i=1}^m \bar{\lambda}_i \nabla g_i(\bar{x}) \right)^T (x - \bar{x}) = 0 \\
 \Rightarrow (\nabla f(\bar{x}))^T (x - \bar{x}) + \left(\sum_{i=1}^m \bar{\lambda}_i \nabla g_i(\bar{x}) \right)^T (x - \bar{x}) = 0 \quad \text{--- (1)}
 \end{array}
 \quad
 \begin{array}{l}
 (P2) \text{ Min } f(x) \\
 \text{s.t.} \\
 g_j(x) \leq 0, j=1,2,\dots,m \\
 f: \mathbb{R}^n \rightarrow \mathbb{R} \\
 g_j: \mathbb{R}^n \rightarrow \mathbb{R}, j=1,2,\dots,m
 \end{array}$$

So, the proof is very easy. See if you want to show the proof. See what are the KKT conditions? What is the problem P 2? The problem P 2 is; problem P 2 is basically minimization of $f(x)$ subject to $g_j(x) \leq 0$ j from 1 to m ok. f is a function from \mathbb{R}^n to \mathbb{R} and g_j is other function from \mathbb{R}^n to \mathbb{R} j from 1 to m ok.

Now, we have to show that a point which is a KKT point, that means satisfy the KKT conditions Karush Kuhn Tucker conditions, then the point will be a global minimum point of the problem P 2 and of course, problem is convex programming problem. So, let us try to prove this result, the proof is easy.

See if we want to show that \bar{x} is a global minimum point of the problem P 2 then what we have to show? We will have to show that $f(\bar{x})$ is less than equal to $f(x)$ for all feasible point x of P 2 this to prove. Because we have to show that \bar{x} is a global minimum point of the

problem P 2. That means, you take any feasible point and for any feasible point of this problem $f(\bar{x})$ should be less than equal to f^* .

And given it is given to us that KKT conditions are satisfied and the problem is a convex programming problem. So, what are what are the KKT conditions?. So, let us go to the first KKT condition. The first KKT condition is gradient of $f(\bar{x})$ plus summation i from 1 to m $\lambda_i \bar{\lambda}_i$ it is $\lambda_i \bar{\lambda}_i$ gradient of $g_i(\bar{x})$ is equal to 0; this is the first condition.

So, now this implies. So, we know that \bar{x} satisfy this condition ok. So, this implies we can use this as gradient \bar{x} plus summation i from 1 to m $\lambda_i \bar{\lambda}_i$ gradient of $g_i(\bar{x})$. So, if it is 0 then this will also be 0 ok. We are access any feasible point of the problem P 2. Now this further implies gradient $f(\bar{x})$ whole transpose $\bar{x} - x^*$ plus summation i from 1 to m $\lambda_i \bar{\lambda}_i$ gradient $g_i(\bar{x})$ whole transpose into, so into $\bar{x} - x^*$ should be equal to 0 ok.

Now, since function and constraints are convex, suppose this is equal to this. This is equation 1.

(Refer Slide Time: 08:29)

$$\begin{aligned}
 f(x) - f(\bar{x}) &\geq (\nabla f(\bar{x}))^T (x - \bar{x}) \quad \text{--- (2)} \\
 g_i(x) - g_i(\bar{x}) &\geq (\nabla g_i(\bar{x}))^T (x - \bar{x}) \\
 \Rightarrow \sum_{i=1}^m \bar{\lambda}_i g_i(x) - \sum_{i=1}^m \bar{\lambda}_i g_i(\bar{x}) &\geq \left(\sum_{i=1}^m \bar{\lambda}_i \nabla g_i(\bar{x}) \right)^T (x - \bar{x}) \quad \text{--- (3)}
 \end{aligned}$$

Add (2) & (3), we get

$$\begin{aligned}
 f(x) - f(\bar{x}) + \sum_{i=1}^m \bar{\lambda}_i g_i(x) - \sum_{i=1}^m \bar{\lambda}_i g_i(\bar{x}) &\geq 0 \quad (\text{from (1)}) \\
 \Rightarrow f(x) - f(\bar{x}) &\geq - \sum_{i=1}^m \bar{\lambda}_i g_i(x) \geq 0
 \end{aligned}$$

Now, since f and g_i for all i are convex. So, by the convexity definition we can say that $f(x) - f(\bar{x})$ is greater than or equal to gradient of f at \bar{x} into $x - \bar{x}$. And also $g_i(x) - g_i(\bar{x})$ is greater than or equal to gradient of g_i at \bar{x} whole transpose into $x - \bar{x}$.

And this further implies, this constraint further implies this inequality further implies. Now since $\bar{\lambda}_i$, see since this $\bar{\lambda}_i$ is greater than or equal to 0 for all i . So, we can say, we can multiply this by $\bar{\lambda}_i$ and sum up all the constraints.

So, what we get; $\sum_{i=1}^m \bar{\lambda}_i g_i(x) - \sum_{i=1}^m \bar{\lambda}_i g_i(\bar{x})$ is greater than or equal to $\sum_{i=1}^m \bar{\lambda}_i (\nabla g_i(\bar{x}))^T (x - \bar{x})$, suppose this is 3 ok.

Now you add 2 and 3 2 and 3 add 2 and 3, so what we get? We left with $f(x)$ minus $f(x)$ bar plus, now this is summation i from 1 to m λ_i bar $g_i(x)$ minus summation i from 1 to m λ_i bar $g_i(x)$ bar is greater than equal to.

So, what we are having in the left hand side? In the left hand side we are having this transpose x minus x bar plus this transpose x minus x bar which from one, from this one is equal to 0 ok. So, we can directly write this is greater than equal to 0 from 1 ok.

Now again you go to KKT conditions λ_i $g_i(x)$ bar is equal to 0 for all i . If it is 0 for all i ; that means, sum is also 0. So, sum is also 0 that means, this quantity this quantity is equal to 0 ok. Because it is what? It is λ_1 $g_1(x)$ bar λ_2 $g_2(x)$ bar and so on up to λ_m $g_m(x)$ bar and all are 0. So, sum will also be 0.

So, we left with this finally, gives $f(x)$ minus $f(x)$ bar is greater than equal to summation i from 1 to m with negative sign λ_i bar $g_i(x)$. Now what this x is? This x is a feasible point of this problem P 2. So, if it is a feasible point of this problem P 2 that means, this constraint are is are satisfied for the for x , and λ_i bar are greater than equal to 0 for all i .

So, that means, that this expression is less than equal to 0 and with negative sign this will be greater than equal to 0 ok. Because $g_i(x)$ is less than equal to 0 for all i and λ_i bar are greater than equal to 0 for all i . So, this implies summation λ_i bar $g_i(x)$ are less than equal to 0 ok.

(Refer Slide Time: 12:03)

$$\begin{aligned} & \left[\begin{array}{l} g_i(x) \leq 0 \quad \forall i \\ \& \quad \bar{\lambda}_i \geq 0 \quad \forall i \\ \Rightarrow \quad \sum_{i=1}^m \bar{\lambda}_i g_i(x) \leq 0 \end{array} \right] \\ \text{Hence, } & \boxed{f(x) \geq f(\bar{x})} \end{aligned}$$

So, hence this is less than equal to 0 negative will give greater than equal to 0. So, what this implies? This implies. So, I am putting it in a bracket, so hence $f(x)$ is greater than equal to $f(\bar{x})$ for any x feasible to the problem P 2 and this implies \bar{x} is a global minimum point of the problem P 2.

So, what we have shown we have shown that if a point is a KKT point that means, satisfy the KKT conditions and the problem is a convex programming problem then that point is the global minimum point to the problem P 2. Now convexity is a important condition, without convexity we may not say that that point is a global minimum point of the problem.

(Refer Slide Time: 13:21)

Remark:

Without the convexity assumptions on f and g_i , the KKT conditions are not sufficient for a point \bar{x} to be a local min/global min point.

For example:

$$\begin{aligned} \text{Min} \quad & -x_2 \\ \text{subject to: } & x_1^2 + x_2^2 \leq 4 \\ & -x_1^2 + x_2 \leq 0. \end{aligned}$$

The point **(0,0)** satisfy KKT-conditions but it is not a local/global min point.

Suppose you have this problem. To understand this let us take this problem. This is minimization of minus x_2 subject to these two constraints.

(Refer Slide Time: 13:30)

$$\begin{aligned}
 \text{Min } & -x_2 \\
 \text{st } & g_1 = x_1^2 + x_2^2 - 4 \leq 0 \\
 & g_2 = -x_1^2 + x_2 \leq 0
 \end{aligned}$$

$$\nabla f(x) + \sum_{i=1}^m \lambda_i \nabla g_i(x) = 0 \Rightarrow \begin{pmatrix} \frac{\partial f}{\partial x_1} & \frac{\partial f}{\partial x_2} \end{pmatrix} + \lambda_1 \begin{pmatrix} \frac{\partial g_1}{\partial x_1} & \frac{\partial g_1}{\partial x_2} \end{pmatrix} + \lambda_2 \begin{pmatrix} \frac{\partial g_2}{\partial x_1} & \frac{\partial g_2}{\partial x_2} \end{pmatrix} = (0, 0)$$

$$\Rightarrow \begin{pmatrix} 0 & -1 \end{pmatrix} + \lambda_1 \begin{pmatrix} 2x_1 & 2x_2 \end{pmatrix} + \lambda_2 \begin{pmatrix} -2x_1 & 1 \end{pmatrix} = (0, 0)$$

$$\Rightarrow \begin{cases} 0 + 2x_1\lambda_1 - 2x_1\lambda_2 = 0 \\ -1 + 2x_2\lambda_1 + \lambda_2 = 0 \end{cases}$$

So, let us see what this problem is, it is minimum of minus x_2 subject to subject to it is x_1 square plus x_2 square minus 4 less than equal to 0 and second is minus x_1 square plus x_2 less than equal to 0, this problem

Now, let us write the KKT condition of this. So, how to write the KKT condition? The first condition is gradient of $f(x)$ plus summation λ_i i from 1 to m gradient of $g_i(x)$ should be 0. This implies, this is g_1 this is g_2 . So, gradient of how many variables? 2 variables. So, what is ∇f , so square is not there.

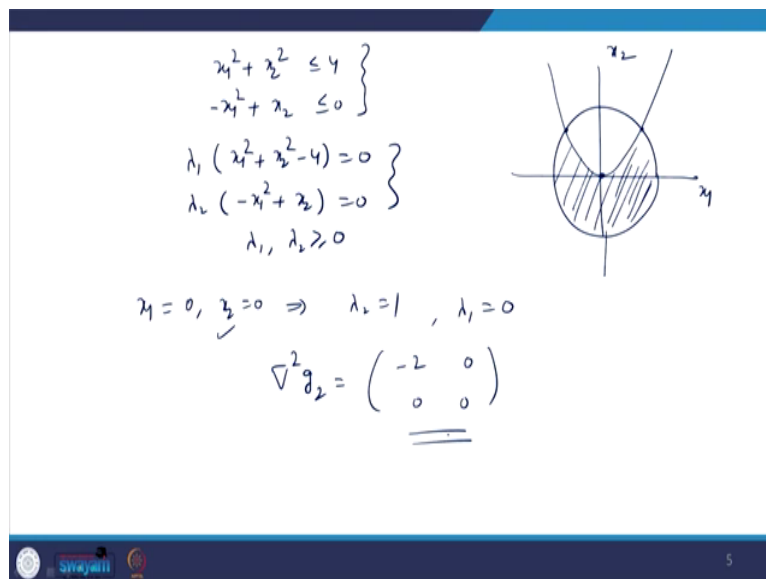

So, gradient of $f(x)$. So, first with respect to x_1 it will be ∇f by ∇x_1 ∇f by ∇x_2 plus will come here actually, λ_1 times gradient of g_1 , so ∇g_1 by ∇x_1 plus ∇ . So, this is not plus this is a vector. So, this is ∇g_1 by ∇x_2 plus λ_2 times ∇g_2 by ∇

x_1 and ∇g_2 by ∇x_2 which is equal to 0 0. This is by the first constraint, first KKT condition.

Now, this further implies, why ∇f by ∇x_1 0, ∇f by ∇x_2 minus 1 plus λ_1 times, ∇f by ∇g_1 by ∇x_1 2 x_1 it is 2 x_2 plus λ_2 times minus 2 x_1 and g_2 is 1 which is equal to 0 0. And this implies 0 plus 2 x_1 λ_1 minus 2 x_1 λ_2 is equal to 0; the first constraint first equation. The second equation is minus 1 plus 2 x_2 λ_1 plus λ_2 2 equal to 0.

So, these are the two constraint which we got from the first KKT condition.

(Refer Slide Time: 16:01)

Handwritten mathematical derivation and a graph of the feasible region for an optimization problem.

Constraints:

$$\left. \begin{aligned} x_1^2 + x_2^2 &\leq 4 \\ -x_1^2 + x_2 &\leq 0 \end{aligned} \right\}$$

KKT conditions:

$$\left. \begin{aligned} \lambda_1 (x_1^2 + x_2^2 - 4) &= 0 \\ \lambda_2 (-x_1^2 + x_2) &= 0 \end{aligned} \right\}$$

Non-negativity conditions:

$$\lambda_1, \lambda_2 \geq 0$$

Optimal point and Lagrange multipliers:

$$x_1 = 0, x_2 = 0 \Rightarrow \lambda_2 = 1, \lambda_1 = 0$$

Hessian matrix:

$$\nabla^2 g_2 = \begin{pmatrix} -2 & 0 \\ 0 & 0 \end{pmatrix}$$

The graph shows a coordinate system with x_1 and x_2 axes. A circle of radius 2 is centered at the origin, representing the constraint $x_1^2 + x_2^2 \leq 4$. A parabola $x_2 = x_1^2$ opens upwards from the origin, representing the constraint $-x_1^2 + x_2 \leq 0$. The feasible region is the area inside the circle and below the parabola, which is shaded with diagonal lines. The origin (0,0) is marked as the optimal point.

What are other KKT conditions let us quickly see for this problem. The other KKT condition is the first, the second one is the feasibility condition that is x_1 square plus x_2 square less

than equal to 4 and minus x_1 square plus x_2 less than equal to 0. This is a feasibility condition.

And next condition is a complimentary condition, that condition is called complimentary condition $\lambda_i g_i = 0$. So, $\lambda_1 g_1 = 0$; g_1 is this condition equal to 0 and $\lambda_2 g_2$ is this condition equal to 0 and $\lambda_1 \lambda_2 \geq 0$. So, these are the various KKT condition for this particular problem.

Now, let us check whether $(0,0)$ is a KKT point or not. KKT point means it satisfies the KKT conditions or not. So, if you put $x_1 = 0$, $x_2 = 0$, so $g_1 = 0$. If it is 0 then λ_1 comes out to be 1. So, λ_1 is 1. So, we are putting x_1 equal to 0 and x_2 equal to 0. So, this implies λ_2 is 1.

So, $0 + 0 < 4$; true, $0 < 0$; true, 0 if it is 0 ; that means, it nonzero so; that means, λ_1 is 0. And $0 = 0$, this is 0, this is 1 and $0 = 0$. So, and $\lambda_1 \lambda_2$ are also non negative. So, we have shown that $(0,0)$ satisfy all the KKT conditions, but still $(0,0)$ for this problem is not a global minimum point. What is the reason? The reason is that this problem is not a convex programming problem.

Why? Because you can see if you draw the graph of this problem, the graph of this problem is you see $x_1^2 + x_2^2 \leq 4$, this is x_1 , this is x_2 . Less than equal to 4 means inside the circle and minus $x_1^2 + x_2^2 \leq 0$ means this parabola and outside this parabola; that means, in inside the circle there is this region.

So, $(0,0)$ is clearly not a global minimum point of this objective function minus x_2 . We are you have to minimize minus x_2 , you have to minimize minus x_2 means you have to maximize x_2 . So, maximize x_2 will be where, maximize x_2 will be at this point or at this point.

So, this point clearly will not be a global minimum point of this function; however, it is a KKT point and the reason why? The reason is, because this feasible region is not a convex set.

Or you can say that this is all if you find the Hessian of the second constraint, Hessian of a second constraint, Hessian of a second constraint del square of g 2 is minus 2 0 0 0. So, this Hessian is not positive semi definite. That means, the constraint g 2 is not a convex function. That means, this problem is not a convex programming problem.

So, what we have concluded? We have concluded that KKT point will be a global minimum point of the problem P 2 only when a given problem, a given p problem P 2 is a convex programming problem. So, that is a sufficient condition.

(Refer Slide Time: 19:38)

Problems

1 Show that $(3/2, 9/4)^T$ is a unique global optimal solution for the following problem:

$$(P1) \quad \text{Min } f(x) = \left(x_1 - \frac{9}{4}\right)^2 + (x_2 - 2)^2$$

subject to $x_1^2 \leq x_2,$
 $x_1 + x_2 \leq 6,$
 $x_1, x_2 \geq 0.$

2 Solve the following problem:

$$(P2) \quad \text{Min } f(x) = x_1^2 + x_2^2 - 6x_1 - 4x_2 + 13$$

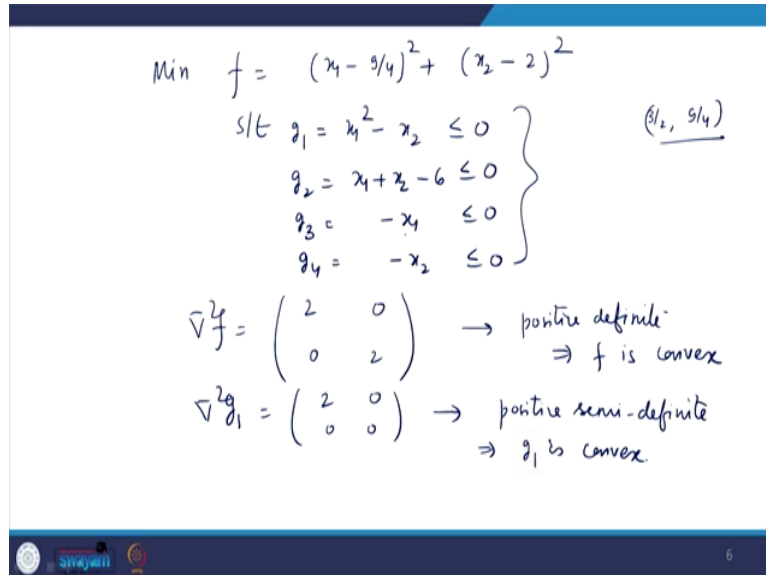

subject to $x_1^2 + x_2^2 \leq 52,$
 $x_1, x_2 \geq 0.$

6

So, here are few examples based on KKT condition, let us discuss one problem say problem 1. So, we have to show that 3 by 2 9 by 4 a unique global minimum global optimal solution the following problem. So, for first we have to show that the problem is a convex programming problem, then we have to write all the KKT conditions and then we have to show that this

point 3 by 2 9 by 4 satisfy all the KKT conditions. This is sufficient to show that 3 by 2 9 by 4 is a global optimal solution of this problem.

(Refer Slide Time: 20:22)

Handwritten mathematical derivation on a slide:

$$\begin{aligned} \text{Min } f &= (x_1 - 9/4)^2 + (x_2 - 2)^2 \\ \text{s.t. } g_1 &= x_1^2 - x_2 \leq 0 \\ g_2 &= x_1 + x_2 - 6 \leq 0 \\ g_3 &= -x_1 \leq 0 \\ g_4 &= -x_2 \leq 0 \end{aligned} \quad \left. \vphantom{\begin{aligned} \text{s.t. } g_1 &= x_1^2 - x_2 \leq 0 \\ g_2 &= x_1 + x_2 - 6 \leq 0 \\ g_3 &= -x_1 \leq 0 \\ g_4 &= -x_2 \leq 0 \end{aligned}} \right\} \quad (9/4, 9/4)$$

$$\nabla^2 f = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} \rightarrow \text{positive definite} \Rightarrow f \text{ is convex}$$

$$\nabla^2 g_1 = \begin{pmatrix} 2x_1 & 0 \\ 0 & 0 \end{pmatrix} \rightarrow \text{positive semi-definite} \Rightarrow g_1 \text{ is convex}$$

So, let us try this problem, its in the same way we can try for this problem solve this problem also. Problem is minimizing f equal to x_1 minus 9 by 4 whole square plus x_2 minus 2 whole square subject to. What are the conditions? The first condition is x_1 square minus x_2 less than equal to 0, suppose this is g_1 . The second constraint is x_1 plus x_2 less than equal to 6. The third constraint is minus x_1 less than equal to 0. The fourth constraint is minus x_2 less than equal to 0.

Now, g_2 is linear so convex, g_3 is linear so convex and g_4 is linear so convex. Let us see for f and g_1 . So, what are Hessian matrix of f ? It is 2 0 0 2. So, this matrix is clearly positive

definite matrix and hence convex. So, f is this, this is positive definite and this implies f is convex.

Now, similarly find Hessian matrix of g_1 , it is $2 \ 0 \ 0 \ 0$ which is again, which is positive semi definite. What we have seen? So, hence we can say that this problem is a convex programming problem. Now let us write the KKT conditions. So, what are the various KKT conditions?.

(Refer Slide Time: 22:10)

$$\begin{aligned} \nabla f(x) + \sum_{i=1}^4 \lambda_i \nabla g_i(x) &= 0 \\ \begin{pmatrix} 2(x_1 - 9/4) & 2(x_2 - 2) \end{pmatrix} + \lambda_1 \begin{pmatrix} 2x_1 & -1 \end{pmatrix} \\ &+ \lambda_2 \begin{pmatrix} 1 & 1 \end{pmatrix} + \lambda_3 \begin{pmatrix} -1 & 0 \end{pmatrix} \\ &+ \lambda_4 \begin{pmatrix} 0 & -1 \end{pmatrix} = (0, 0) \\ \Rightarrow \begin{cases} 2(x_1 - 9/4) + 2x_1\lambda_1 + \lambda_2 - \lambda_3 = 0 \\ 2(x_2 - 2) - \lambda_1 + \lambda_2 - \lambda_4 = 0 \end{cases} \rightarrow \begin{cases} 2(\frac{1}{2} - \frac{9}{4}) + \lambda_1 = 0 \\ 2(-\frac{3}{4}) + \lambda_2 = 0 \end{cases} \\ \lambda_1(x_1^2 - x_2) = 0 = \lambda_2(x_1 + x_2 - 6) = \lambda_3 x_1 = \lambda_4 x_2 \\ \lambda_1, \lambda_2, \lambda_3, \lambda_4 \geq 0 \\ \Rightarrow \lambda_1 = \frac{1}{2}, \lambda_2 = \frac{3}{2}, \lambda_3 = 0, \lambda_4 = 0, \lambda_2 = 0 \\ \Rightarrow 2(\frac{9}{4} - 2) - \frac{1}{2} = \frac{9}{2} - 4 - \frac{1}{2} = \frac{9}{2} - \frac{9}{2} = 0 \end{aligned}$$

So, KKT conditions of the first KKT condition first KKT condition is gradient of $f(x)$ plus summation λ_i gradient of $g_i(x)$ equal to 0. Here i is from 1 to 4, because there are four constraints. So, what is gradient of $f(x)$? Gradient of $f(x)$ will be, you find the gradient of this f , so gradient will be twice x_1 minus 9 by 4 twice x_2 minus 2 plus λ_1 times gradient of

first constraint, which is $2x_1$ for x_1 and -1 for x_2 plus λ_2 . For λ_2 it is 1 , for λ_3 it is -1 , for λ_4 it is 0 minus 1 is equal to 0 .

So, this implies twice of x_1 minus 9 by 4 plus $2x_1$ λ_1 plus λ_2 minus λ_3 equal to 0 . The second will be twice of x_2 minus 2 minus λ_1 plus λ_2 minus λ_4 equal to 0 .

So, these are the two conditions which you obtain from the first KKT condition. Next are the feasibility conditions. So, feasibility conditions are the same conditions, these are the feasibility conditions.

Next are the complimentary condition. The complimentary condition is λ_1 time the first constraint the first constraint is $x_1^2 - x_2$, this is equal to 0 which is equal to this is equal to 0 which is equal to λ_2 times x_1 plus x_2 minus 6 which is equals to λ_3 x_1 which is equals to λ_4 x_2 and λ_1 , λ_2 , λ_3 , λ_4 all must be greater than equal to 0 .

Now, now what to show? We have to show that this point 3 by 2 9 by 4 is the global optimal point of this problem. That means, it must satisfy the KKT conditions ok. So, x_1 is 3 by 2 and x_2 is 9 by 4 . So, you substitute first you substitute it here. So, what is x_1^2 ?

So, first you first you see whether it is feasible or not ok. So, first we will see the feasibility. So, 3 by 2 and 9 by 4 , 3 by 2 and 9 by 4 . So, you substitute 3 by 2 is greater than equal to 0 , 9 by 4 is greater than equal to 0 , 3 by 2 plus 9 by 4 is what? It is 6 by 4 plus, 6 by 4 means 15 by 4 minus 6 which is less than equal to 0 that is true. And $x_1^2 - x_2$, 9 by 4 minus 9 by 4 is 0 which is equal to 0 . So; that means, first thing is clear that this point is a feasible point.

Now, the other conditions. Now this is x_1 is non 0 and λ_3 into x_1 is equal to 0 , so this implies λ_3 equal to 0 and similarly λ_4 is also 0 . And x_1 is 3 by 2 and x_2 is 9 by 4 . So, and this is this sum will be 15 by 4 which is not 6 ; that means, this is not 0 . That means,

λ_2 will come out to be 0. From this we cannot say anything, λ_1 may or may not be 0 because this is 0.

So, these three we have obtained. Now λ_3 is 0, λ_2 is 0 and x_1 is 3 by 2. So, from here you can calculate λ_1 . So, what will be λ_1 from this condition? It is 2×3 by 2 minus 9×4 minus 2×3 by 2 plus 2×3 by 2 into λ_1 . These two are 0 which is equal to 0.

So, what we have obtained from here? So, these two will cancel with this two. So, this is nothing, but 2×3 is 6×4 that is 24 plus $3 \lambda_1$ equal to 0. So, this implies λ_1 is equal to. So, 24 cancels out 1×2 ok. Now only one condition left; λ_1 is also non negative only one condition to check. So, 9×4 minus 2 . So, let us compute it here.

So, $2 \times 9 \times 4$ minus 2 , λ_1 is 1×2 , λ_2 is 0, λ_4 is 0. So, this is 0, this must be 0. So, let us check, so this is equal to what? This is 9×2 minus 4 minus 1×2 . So, this is again 9×2 the 9×2 minus 9×2 which is 0. That means, this condition is also satisfied. Hence we can say that this point satisfies all the KKT conditions.

So, hence by the sufficiency KKT conditions we can say that this point is a global minimum point of this problem ok. In the same way we can solve the problem P 2 also. You write the KKT, you first check whether it's a convex programming problem or not. If it's a convex programming problem then you write the KKT conditions and try to find a point x which satisfies all the KKT conditions, that will be the global minimum point to the problem P 2.

So, in this lecture we have seen that if we have given a non-linear programming problem and it is a convex programming problem. Then to solve such problems you just write the KKT conditions ok. Try to solve the KKT condition and a point will satisfy the KKT conditions will be a global minimum point of the problem if it is a convex programming problem.

Thank you very much.
