Lecture - 29
Steepest Descent Method

Hello friends. Welcome to lecture series on Essential Mathematics for Machine Learning. So however, we have seen analytical matrix to solve our non-linear problems. We have seen if a problem is a convex optimization problem, then the KKT conditions become sufficient. We can write the KKT condition and solve a problem a non-linear problem.

Now, always analytic methods may not work; because of the complexity of the problem, because the problems are not convex or because of some other reason. So, we have some such techniques numerical such techniques to handle such problems. So, this lecture is basically devoted to numerical optimization algorithms; that what numerical optimization algorithm which are useful in machine learning.

So, first let us understand; if you are having an unconstrained optimization problem. We have already discussed what unconstrained means. Unconstraint means; without any constraint without any restrictions.

(Refer Slide Time: 01:28)

Unconstrained optimization problems

Consider the following unconstrained minimization problem:

$$(P) \quad \min_{x \in \mathbb{R}^n} f(x).$$

The question arises how to find a point $\bar{x} \in \mathbb{R}^n$ which solves (or at least approximately solves) (P). Because in general, our analytical approach may not work for all types of optimization problems. So, we move to search techniques.

So; that means, we have to simply minimize $f(x)$ subject to x belongs to \mathbb{R}^n . If we have this problem and we want to minimize it. So, so, the question arises; how can you find a point \bar{x} in \mathbb{R}^n which solves the problem p or at least approximately solve the problem p . Because, in general our analytical approach may not work for all types of optimization problems. So, we move to such techniques or numerical optimization algorithms.

(Refer Slide Time: 02:01)

Basic scheme

A common basic scheme is of the form:

$$x_{k+1} = x_k + \alpha_k d_k$$

where x_k is the current solution, d_k is the direction of movement from x_k and $\alpha_k > 0$ is the step size (distance upto which we move from x_k in the direction d_k).
How to find α_k and d_k to find next iteration x_{k+1} such that we move to the solution of (P) in an efficient manner?

3

So, what is the basic scheme? See, the basic scheme of any algorithm of any numerical algorithm is; we have a initial we have a current point x_k a direction d_k from x_k there are. So, many directions say if you are having a point x_k .

(Refer Slide Time: 02:20)

If you are having a point x_k from this x_k there are infinite directions in which direction we should move. So, that direction is basically d_k the optimal direction. α_k is a step size, optimal step size and using this relation x the next iteration $x_k + 1$ which is equal to x_k plus $\alpha_k d_k$ the next iteration $x_k + 1$ can be found.

So, here x_k is the current solution, d_k is the direction of movement from x_k and α_k is a step size. The distance up to which we move from x_k in the direction of d_k to obtain $x_k + 1$ ok. Now how to find α_k and d_k ? This α_k and d_k these are not known to us, only x_k the current solution is known to us. How can you find α_k and d_k such that we get $x_k + 1$ from x_k in an efficient way ok? So, this is the next question.

So, if we have having a minimization type problem as we have discussed here the minimization type problem.

(Refer Slide Time: 03:29)

Descent property

An algorithm for solving (P) is said to have a descent property if $f(x_{k+1}) < f(x_k)$ for all k . That is, as we proceed, the value of objective function should decrease.

Order of convergence

Let a sequence $\{x_k\}$ converge to a point \bar{x} and let $x_k \neq \bar{x}$ for sufficiently large k . The quantity $\|x_k - \bar{x}\|$ is called the error of the k^{th} iteration. Suppose there exist p and $0 < \alpha < \infty$ such that

$$\lim_{k \rightarrow \infty} \frac{\|x_{k+1} - \bar{x}\|}{\|x_k - \bar{x}\|^p} = \alpha,$$

then p is called the order of convergence of the sequence $\{x_k\}$.

4

Then we have descent property. What is a descent property? See, if we are moving from a current solution x_k to x_{k+1} such that the value of f at x_{k+1} is less than value of f at x_k ; that means, we are going in a descent direction.

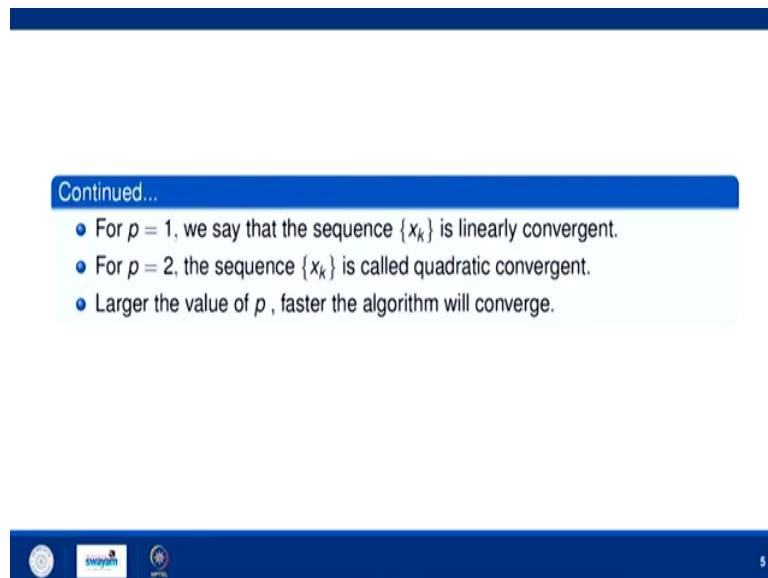

If it is a maximization type and f_{k+1} is more than f_k , then we say that this is an ascent direction ok. So, an algorithm were solving a P is said to have a descent property if this inequality holds for every k and that is as we proceed the value of objective function decreases.

Now, if you are developing any algorithm any numerical algorithm. So, we have certain terms related to that algorithm. First is order of convergence. What is the order of convergence of that algorithm? So, how we define order of convergence? So, let a sequence x_k converges to a point \bar{x} ok.

And let x_k is not equal to \bar{x} for sufficiently large k . The quantity the norm of x_k minus \bar{x} is called the error of the k th iteration of course, because x_k converges to \bar{x} and the norm of x_k minus \bar{x} because we have to anyhow approach to x_k . So, this is nothing but the error term at the k th iteration.

Suppose there exists a p and α been between 0 and infinity such that norm of x_{k+1} minus \bar{x} divided by norm of x_k minus \bar{x} whole raise to power p as limit k tends to infinity if it is α . Then p is called order of convergence of sequence x_k ; that means, this must be this value must be finite. If this value is finite for some p , then that p is called order of convergence of sequence x_k ok.

(Refer Slide Time: 05:40)

Continued...

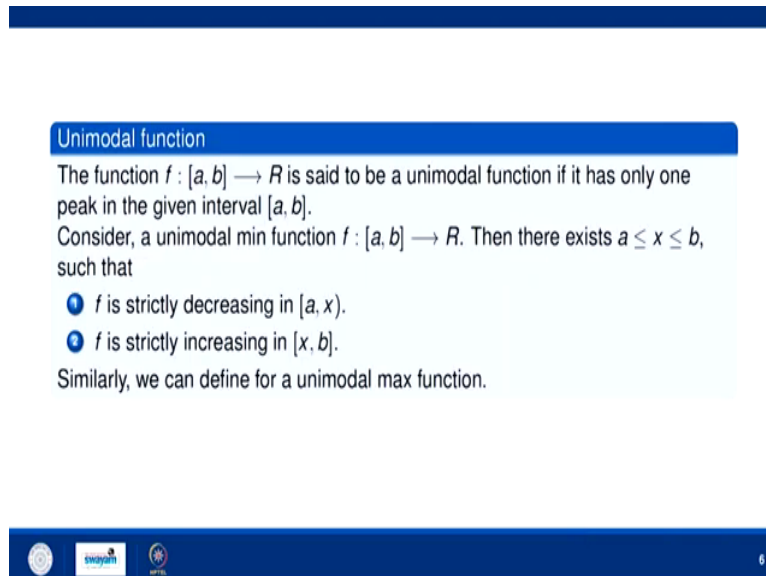

- For $p = 1$, we say that the sequence $\{x_k\}$ is linearly convergent.
- For $p = 2$, the sequence $\{x_k\}$ is called quadratic convergent.
- Larger the value of p , faster the algorithm will converge.

5

Now, if p equal to 1, if for some algorithm; the sequence x_1, x_2, x_3 up to x_k and. So, on if that sequence converges for p equal to 1, then we say that the sequence is linearly convergent ok. If in this p comes out to be 1; that means, that sequences linearly convergent. If p equal to 2, then we say that sequence is quadratic convergent or convergent of order 2.

Of course a larger value of p , what indicates a larger value of p if you are having $p = 3, 3.5$ or something for some algorithms; that means, the algorithm is faster. The larger value of p indicate the faster the algorithm will converge ok.

(Refer Slide Time: 06:29)

Unimodal function

The function $f : [a, b] \rightarrow R$ is said to be a unimodal function if it has only one peak in the given interval $[a, b]$.

Consider, a unimodal min function $f : [a, b] \rightarrow R$. Then there exists $a \leq x \leq b$, such that

- 1 f is strictly decreasing in $[a, x]$.
- 2 f is strictly increasing in $[x, b]$.

Similarly, we can define for a unimodal max function.

6

Now, we are having unimodal function. What do you mean by unimodal function? The function f from an interval a to b . Now this initial interval is called interval of uncertainty. See, you are having an interval a to b and you are interested to find out point x which is the optimal solution of a given unconstrained optimization problem. So, this initial interval is called interval of uncertainty.

So, this problem the function from a to b is said to be unimodal function if it has only one peak in the given interval a to b ; if it is only one peak either minima or maxima only one peak is called unimodal function. Let us suppose you are having a unimodal minimum function f from a to b then, there exists x between a and b such that. See, if you are having a unimodal function, if you are having a unimodal minimum function.

(Refer Slide Time: 07:29)

So, it may be of this type which is only one peak. So, it is unimodal minima and minimum also. So, it is unimodal minimum function.

So, if you are saying that this is I initial interval of uncertainty a b. If you are saying that these are this is a initial interval of uncertainty a b, then these are close interval a b. So, these points are also inclusive then; that means, that it first decreases up to some point and then increases, because it is a unimodal minimum function. So, that is what I have stated here that first of all there will be a x in between a and b and that access the minimum point where it first strictly decreases from a to x and then increases from x to b .

Now, similarly we can define unimodal minimum maximum function.

(Refer Slide Time: 08:38)

Continued...

Let $f(x)$ be the unimodal min function on the interval of uncertainty $[a, b]$. Take two distinct points (called experiments) x_1 and x_2 such that $x_1 < x_2$, then the following cases may arise

- $f(x_1) < f(x_2) \Rightarrow x_{min} \in [a, x_2]$
- $f(x_1) > f(x_2) \Rightarrow x_{min} \in [x_1, b]$
- $f(x_1) = f(x_2) \Rightarrow x_{min} \in [x_1, x_2]$.

Now, in unimodal minimum function, the various cases may arise. So, let us discuss these cases now.

(Refer Slide Time: 08:44)

Suppose, you are having in between a and b, you are having two experiment x_1 and x_2 . So, this is y equal to $f(x)$ a function ok, this is a and this is some point b, this is the initial interval of uncertainty a b.

Now, you are having 2 experiments here. Now the two point x_1 x_2 may be any where in between a and b. And let us suppose x_1 is less than x_2 and between a and b. So, let us suppose x_1 is here and suppose x_2 is here. So, in this case in this case $f(x_1)$ is more than $f(x_2)$ because this height is more than this height.

So, where does maximum belongs to? It implies x_{\min} will belongs to which interval see this x_{\min} is somewhat here ok. Now this x_2 may be here also this x_2 may be here also. So, we can say because this is $f(x_1)$ is less than $f(x_2)$. So, this point may be here also. So, we can say that this belongs to x_1 to b. Because x_1 cannot be here, if x_1 is here

because x_1 is less than x_2 and if x_1 is here it is increasing. So, this when equality will not hold ok.

(Refer Slide Time: 10:26)

Now, the second case which may arise is, this is a this is b the second case which may arise is x_1 is somewhat here and x_2 is somewhat here; that means, $f(x_1)$ is less than $f(x_2)$. So, x_{\min} belongs to in which interval? See, now x_1 is less than x_2 . So, this x_1 may be here also; may be here also ok, but this x_2 cannot be here because x_1 is less than x_2 .

So, we can say that minimum always belongs to a to x_2 in any case whether x_1 is here or here minima always belongs to a to x_2 . So, these are second case 2.

(Refer Slide Time: 11:26)

Now, what is the case 3? Case 3, it may be that you are having unimodal minimum function like this, this is a point a, this is a point b. And the 2 experiments which we have find which you have found x_1 and x_2 , you are having 2 experiments such that $f(x_1)$ is equal to $f(x_2)$ ok.

So, you will be having only 3 cases; either $f(x_1)$ will be less than $f(x_2)$ or $f(x_1)$ is more than $f(x_2)$ or $f(x_1)$ is equal to $f(x_2)$ if it is a if it is equation then this implies $x_{minimum}$ will belongs to of course, in between x_1 and x_2 , $x_{minimum}$ is here somewhat here. So, that is basically unimodal function. So, if we are dealing with a unimodal function and we are finding experiments by any method then either these three cases may arise.

So, if you have a unimodal function by any experiments you find experiments x_1 and x_2 , then each time you are reducing the size of the experiment ok. See, if x_1 x_2 are like this that $f(x_1)$ is less than $f(x_2)$ then $x_{minimum}$ will belong to this then; that means, now the new

interval of uncertainty is $a \pm 2$ instead of $a \pm b$ and then you will perform the same method on this interval.

And if again it comes out to be this, then again the size of the interval will decrease and the process proceed; continue till you get the required accuracy.

(Refer Slide Time: 13:12)

Measure of effectiveness

The measure of effectiveness of any search technique, α is defined as

$$\alpha = \frac{L_n}{L_0}$$

where, L_n is the width of interval of uncertainty after n -experiments and L_0 is the initial width of uncertainty.

The slide is a presentation slide with a blue header and footer. The header contains the title 'Measure of effectiveness'. The main content area has a light blue background and contains the definition of α and the formula. The footer contains logos for 'swayam' and 'NPTEL' and the page number '8'.

Now, how we can find out measure of effectiveness of an algorithm? So, that will be a simply given by width of the n th interval of uncertainty divided by initial width of uncertainty. So, that is basically alpha and this alpha is always less than 1. So, this is how we can defined measure of effectiveness.

(Refer Slide Time: 13:35)

Steepest Descent method

Consider the following unconstrained minimization problem:

$$\min_{x \in \mathbb{R}^n} f(x)$$

where f has continuous first order partial derivatives in \mathbb{R}^n .

Choose the starting point as X_1 and move toward the optimal point according to the following rule:

$$X_{k+1} = X_k + \lambda_k d_k$$

where $d_k = -\nabla f(X_k)$ and λ_k is the optimal step size which can be obtained by $\min\{f(X_k + \lambda_k d_k)\}$.

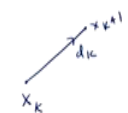

Stopping rule: $\|\nabla f(X_k)\| < \epsilon$ or $\|f(X_{k+1}) - f(X_k)\| < \epsilon'$.

Now, let us come to the first method; which is steepest descent method. Now what is a steepest descent method? See suppose you are having an unconstrained optimization problem of this type minimization of $f(x)$ x belongs to \mathbb{R}^n . Where f has continuous first order partial derivatives in \mathbb{R}^n ok. Now what is the numerical algorithm the algorithm is you first choose a starting point as x_1 . We can take a point initial point as x_1 or initial guess as x_1 and move toward the optimal point according to the following rule.

So, rule is the same rule which we have discussed initially that; X_{k+1} is X_k plus here λ_k instead of α_k you are having λ_k $\lambda_k d_k$. Now d_k is the direction and here is a minimization type problem. So, that direction must be must have descent property descent property means that f of X_{k+1} should be less than f at X_k and λ_k is the optimal step size which can be obtained by this. So, how we will obtain this? Let us discuss.

(Refer Slide Time: 14:50)

Steepest descent method

$$d_k = -\nabla f(x_k)$$
$$x_{k+1} = x_k + \lambda_k d_k$$
$$\min_{\lambda_k} f(x_{k+1})$$

22

So, first of all first of all in a steepest descent method, this point is x_k it may be x_1 x_2 or any one any point. From this x_k as we already discussed there are in finite direction in which direction we should move that that is the first thing.

Now, it is a minimization type problem and we know that the rate of change of a function decreases most rapidly if we move along negative of gradient of f so; that means, if we move along negative of gradient of f at this point x_k and take that as a descent direction. So, that will definitely the direction where the value of the f decreases.

Now, the question is how we can find out the optimal step size see we have find a direction d_k which is nothing but negative of gradient of f at x_k ok. And x_{k+1} is nothing but x_k plus $\lambda_k d_k$. Now this the α_k is nothing, but this α_k is see from here we have

to reach a point x_{k+1} and this is the step size. So, how we can find out the optimal step size?

So, if we put this x_{k+1} this f of x_{k+1} and if you minimize this over λ_k then this will give the optimal step size ok. So, let us discuss it by an example first you will see few properties of this and what is the stopping rule up to how much we have to perform this iterations. We first start with x_1 then find x_2 x_3 and so on. So, the stopping rule is either norm of gradient of x_k should be less than epsilon is the tolerance level which will be given to you or the difference of the 2 successive algorithm 2 successive iterations, the value of f and a 2 sub save iterations the norm of this should be less than epsilon dash that is the stopping rule.

(Refer Slide Time: 17:14)

Steepest Descent algorithm

- is globally convergent.
- has order of convergence unity.
- has descent property.

Example

Use the steepest descent method to minimize $f(x_1, x_2) = x_1^2 - x_1x_2 + x_2^2$ such that $|f(X_{k+1}) - f(X_k)| < 0.05$. Take $X_1 = \left(1, \frac{1}{2}\right)^T$.

10

Now, what are properties of this method. The first property is, it is globally convergent ok. The second property is it has order of convergence unity; that is p equal to 1 for this case and it has a descent property. Of course, it a descent property it; that means, $f(x_{k+1})$ is less than $f(x_k)$ for all k . So, that is the important property and it is very easy to understand, easy to apply that is why we are using this algorithm in machine learning.

So, let us discuss this method by a example. Suppose you want to minimize this function $x_1^2 - x_1 x_2 + x_2^2$ such that we want at the difference of two consecutive values should be less than 0.05 and it is given to us that initial guess as 1 and half.

(Refer Slide Time: 18:14)

$$\begin{aligned}
 \text{Min } f &= x_1^2 - x_1 x_2 + x_2^2 \\
 x_1 &= \left(1, \frac{1}{2}\right)^T \quad \nabla f = \begin{pmatrix} 2x_1 - x_2 & -x_1 + 2x_2 \end{pmatrix}^T \\
 \nabla f(x_1) &= \begin{pmatrix} \frac{3}{2} & 0 \end{pmatrix}^T \\
 d_1 &= -\nabla f(x_1) = \begin{pmatrix} -\frac{3}{2} & 0 \end{pmatrix}^T \\
 x_2 &= x_1 + \alpha_1 d_1 = x_1 + \alpha_1 \begin{pmatrix} -\frac{3}{2} & 0 \end{pmatrix}^T \\
 &= \begin{pmatrix} 1 & \frac{1}{2} \end{pmatrix}^T + \alpha_1 \begin{pmatrix} -\frac{3}{2} & 0 \end{pmatrix}^T \\
 x_2 &= \begin{pmatrix} 1 - \frac{3}{2}\alpha_1 \\ \frac{1}{2} \end{pmatrix}
 \end{aligned}$$

So, what is the problem? Problem is minimization of f which is equal to $x_1^2 - x_1 x_2 + x_2^2$ this is the problem ok.

So, what is the initial guess? Initial guess is $\begin{bmatrix} 1 \\ 1/2 \end{bmatrix}$. So, first let us find gradient of f . So, what is gradient of f ? Grad of is $2x_1 - x_2$ here it is $-x_1 + 2x_2$ whole transpose. So, this will be the gradient of f .

Now, what is gradient of f at x_1 at initial guess as x_1 . So, put x_1 equal to 1 and x_2 equal to half. So, $2 - 1/2$ is $3/2$ and it is $1/2$ so, that is 0. So, it is 0 transpose. So, this will be gradient of f . Now what will be $d_1 d_1$ is nothing, but negative of gradient of f x_1 and that will be nothing but $-3/2$ and 0 transpose ok.

So, the x_2 from the steepest descent method by the recursive algorithm that will be nothing but x_1 plus α_1 or $\lambda_1 d_1$, that will be nothing but x_1 plus α_1 times $-3/2$ comma 0. So, that is this transpose. So, what is x_1 ? x_1 is $\begin{bmatrix} 1 \\ 1/2 \end{bmatrix}$ transpose plus α_1 minus $3/2$ 0 whole transpose. So, that will be $\begin{bmatrix} 1 \\ 1/2 \end{bmatrix} - \alpha_1 \begin{bmatrix} 3/2 \\ 0 \end{bmatrix}$. So, that will be x_2 .

Now, how to find x_2 ? You simply substitute this point in this function and now it will be a function of single variable α_1 and try to minimize that function. We have to find out α_1 for which that f , f is minimum. So, simply substitute this over here.

(Refer Slide Time: 20:29)

$$\begin{aligned}
 f(x_2) &= \left(1 - \frac{3}{2}\alpha_1\right)^2 - \left(1 - \frac{3}{2}\alpha_1\right)\left(\frac{1}{2}\right) + \frac{1}{4} \\
 \frac{df}{d\alpha_1} &= 0 \Rightarrow 2\left(1 - \frac{3}{2}\alpha_1\right)\left(-\frac{3}{2}\right) + \frac{3}{4} = 0 \\
 \frac{d^2f}{d\alpha_1^2} &> 0 \rightarrow \text{minima} \quad -3 + \frac{9}{2}\alpha_1 + \frac{3}{4} = 0 \\
 &\Rightarrow \frac{9}{2}\alpha_1 = 3 - \frac{3}{4} = \frac{9}{4} \\
 &\Rightarrow \alpha_1 = \frac{1}{2} \\
 x_2 &= \left(\frac{1}{4} \quad \frac{1}{2}\right)^T \\
 \|f(x_2) - f(x_1)\|
 \end{aligned}$$

So, let us try to find out. So, what is $f(x_2)$? $f(x_2)$ will be $f(x_2)$ is you replace here you replace x_1 by $1 - \frac{3}{2}\alpha_1$. So, you replace x_1 by $1 - \frac{3}{2}\alpha_1$ whole square minus $1 - \frac{3}{2}\alpha_1$ and x_2 is what? x_2 is half. So, it is half and plus 1 by 4.

So, now it is a function of single variable α_1 . So, your differentiate with respect to α_1 and put it equal to 0 for maxima and minima. So, it will be 2 times $1 - \frac{3}{2}\alpha_1$ minus $\frac{3}{2}$ plus $\frac{3}{4}$ and put it equal to 0. Second derivative is of course, second derivative here is positive; that means, minima. Second derivative with respect to α_1 is positive; that means, minima ok.

So, let us compute α_1 from here. So, 2 2 cancels out. So, it is nothing but minus 3 and it is plus 9 by 2 α_1 plus 3 by 4 equal to 0. So, that will be this implies 9 by 2 α_1

should be equal to 3 minus 3 by 4. So, it is 12 minus 3 that is 9. So, which is 9 by 4 alpha 1. So, this 9 by 4. So, this is simply 9 by 4 and this imply alpha 1 is 1 by 2.

So, in this way we obtain alpha 1. So, what will be x_1 x_2 now? So, x_2 is nothing but, now I substitute alpha 1 here alpha 1 is what? 1 by 4. So, 1 by 4; that means, it is 1 by 4 and half. So, it is 1 by 4 and half whole transpose. So, this is x_2 . Now we will compute $f(x_2)$ minus $f(x_1)$ and it is norm or modulus.

We will see whether this value is less than 0.05 or not, because that is a stopping rule here, that is a stopping rule here. If this is come out to be less than 0.05; that means, we will take x_2 as we will take x_2 as the approximate solution of this given problem. So, what is what is this value?

(Refer Slide Time: 23:06)

Solution

$$f(X_1) = f\left(1, \frac{1}{2}\right) = \frac{3}{4}, \quad \nabla f(x_1, x_2) = (2x_1 - x_2, -x_1 + 2x_2)^T$$

$$\text{and } \nabla f(X_1) = \left(\frac{3}{2}, 0\right)^T = -d_1$$

$$X_2 = X_1 + \lambda_1 d_1$$

$$= \left(1, \frac{1}{2}\right)^T + \lambda_1 \left(-\frac{3}{2}, 0\right)^T = \left(1 - \frac{3}{2}\lambda_1, \frac{1}{2}\right)^T$$

Now, to determine, λ_1 ,

$$f(X_2) = f\left(1 - \frac{3}{2}\lambda_1, \frac{1}{2}\right) = \left(\frac{2-3\lambda_1}{2}\right)^2 - \left(\frac{2-3\lambda_1}{4}\right) + \frac{1}{4}$$

$$\frac{df(X_2)}{d\lambda_1} = 0 \implies \lambda_1 = \frac{1}{2}$$

Therefore, $X_2 = \left(\frac{1}{4}, \frac{1}{2}\right)^T$. Since $|f(X_2) - f(X_1)| = 0.75 \not< 0.05$

11

So, now we will see here. So, we have we have find I have shown for X_2 and the you can you can verify that $f(X_2) - f(X_1)$ is 0.75 which is not less than 0.05. So, hence this means we have to proceed further.

(Refer Slide Time: 23:25)

Continued...

So find the next iteration,
Now,

$$X_3 = X_2 + \lambda_2 d_2$$

$$= \begin{pmatrix} 1 & 1 \\ 4 & 2 \end{pmatrix}^T + \lambda_2 \begin{pmatrix} 0 & -3 \\ 4 & 4 \end{pmatrix}^T, d_2 = -\nabla f(X_2)$$

$$= \begin{pmatrix} 1 & 1 \\ 4 & 2 \end{pmatrix}^T - \frac{3}{4} \lambda_2 \begin{pmatrix} 0 & 1 \\ 4 & 4 \end{pmatrix}^T$$

$$f(X_3) = \frac{1}{16} - \left(\frac{1}{2} - \frac{3}{4} \lambda_2 \right) \left(\frac{1}{4} \right) + \left(\frac{1}{2} - \frac{3}{4} \lambda_2 \right)^2$$

$$\frac{df}{d\lambda_2} = 0 \Rightarrow \lambda_2 = \frac{1}{2}$$

Hence, $X_3 = \begin{pmatrix} 1 & 1 \\ 4 & 8 \end{pmatrix}^T$. Also, $|f(X_3) - f(X_2)| = \frac{9}{64} < 0.05$.

So, in the same way we will find X_3 now. Now X_3 will be given as X_2 plus $\alpha_2 d_2$ or $\lambda_2 d_2$, both are both are ok. So, $\lambda_2 d_2$, X_2 is what? X_2 from here is $\begin{pmatrix} 1 & 1 \\ 4 & 2 \end{pmatrix}^T$. So, you can substitute X_2 as $\begin{pmatrix} 1 & 1 \\ 4 & 2 \end{pmatrix}^T$ λ_2 is λ_2 and d_2 ; how you will find d_2 ? d_2 is nothing but negative of gradient of f at X_2 .

So, gradient of f we have already computed, gradient of f is this. So, you have to find now gradient of f at X_2 . X_2 is $\begin{pmatrix} 1 & 1 \\ 4 & 2 \end{pmatrix}^T$. So, you substitute X_1 as $\begin{pmatrix} 1 & 1 \\ 4 & 2 \end{pmatrix}^T$ and X_2 is $\begin{pmatrix} 1 & 1 \\ 4 & 2 \end{pmatrix}^T$ and find out gradient of f at X_2 at this point. So, we will obtain this ok. Now

again we substitute this X_3 in the function and try to minimize try to find out that λ_2 for which, for which f is minimum and after solving again you will get λ_2 as half.

So, when you substitute λ_2 equal to half here we will get X_3 as $1 \frac{1}{4}$ or 1.25 ok. And now if you find out the mod of $f(X_3)$ minus $f(X_4)$, it comes out to be $9 \frac{1}{64}$, which is less than 0.05 . Now we will stop here and we will say that X_3 is the approximate optimal solution of the given problem.

So, in this way we have seen that; if we are having a non-linear unconstrained optimization problem, then using a steepest descent method we can find out at least approximate optimal solution of a given problem. In the next lecture we will see some more numerical such techniques for solving constrained optimization problems.

Thank you.
