Lecture - 38
Concepts of Duality

Hello friends. Welcome to lecture series on Essential Mathematics form Machine Learning. In the last lecture, we have seen few concepts of ah machine learning; fundamentals of support vector machines. Now, in this lecture we will see the Concepts of Duality which we will use in soft margin or hard margin classifiers.

The concept of duality is important to find out Lagrange function to find out the dual of a given problem so that, it will be computationally the problem will become computationally easy to solve.

(Refer Slide Time: 01:01)

The slide is titled "Introduction" in a blue header. Below the header, there is a light blue box containing three bullet points. At the bottom of the slide, there is a dark blue footer containing logos for UGC, swayam, and MPPE, along with the number 2.

- Duality is used in mathematical programming for many theoretical and computational developments in diverse fields including operations research, management science and economics.
- The duality principle connects two programs: one, the primal which is a constrained minimization (or maximization) problem and other called the dual which is a constrained maximization (or minimization) such that the existence of optimal solution to one of them ensures an optimal solution to other and optimal values of the two are equal.
- Results developed in duality theory have helped develop numerical algorithms for solving certain optimization problems.

So, what do you mean by duality and how can you find out dual of a general non-linear problem? So, first it is some introduction. So, duality is used in mathematical programming for many theoretical and computational developments in diverse fields including operation research, management science and economics.

The duality principle what a duality principle is? The duality principle connects two programs: one, the primal which is the constraint minimization or maximization problem and the other is called the dual for which is a constraint maximization or minimization. Such that the existence of optimal solution to one of them ensures an optimal solution of the other and the optimal values of the two are.

So, the main important concept behind duality is that, we have 2 problems. Problem 1, problem 2; is connect it connect the 2 problem in such a way that if you are having the optimal

solution of the 1 problem say 1, if you have the optimal solution of a problem 1; then it will ensure the optimal solution of the other problem 2 also, and the objective value of both the problems are equal.

So, that is the main concept of duality principle. Now, why duality? So, results developed in duality theory have helped develop various numerical algorithms for solving certain optimization problems. So, it is required to in developing various numerical optimization algorithms.

(Refer Slide Time: 02:35)

Constrained optimization problem

The general form of a constrained optimization problem is given as:

$$(P) \quad \text{Min} \quad f(x) \\ \text{s/t} \quad g_i(x) \leq 0; \quad i = 1, 2, \dots, m$$

where $f: \mathbb{R}^n \rightarrow \mathbb{R}$, $g_i: \mathbb{R}^n \rightarrow \mathbb{R}$; $i = 1, 2, \dots, m$.

Lagrangian function

The Lagrangian function for the problem (P) is defined as:

$$L(x, \lambda) = f(x) + \sum_{i=1}^m \lambda_i g_i(x) = f(x) + \lambda^T g(x)$$

where $x \in \mathbb{R}^n$, $\lambda \in \mathbb{R}^m$ and $g(x) = (g_1(x), g_2(x), \dots, g_m(x))^T$.

3

So, now the question is how can we write the dual of a given non-linear optimization problem? So, suppose we have this non-linear optimization problem; minimization of a function $f(x)$ subject to $g_i(x) \leq 0$; i from 1 to m , so there are m number of constraints and we have a single objective f which is to be minimized.

So, this problem we are calling as problem P. So, where this function f is from $\mathbb{R}^n$ to $\mathbb{R}$; that means, there are n number of unknowns g_i are the function from $\mathbb{R}^n$ to $\mathbb{R}$; for all i . Now, to find out the dual of this problem P, let us first write the Lagrange function of this problem. How we define a Lagrange function? So, Lagrange function is basically function of two parameters x and λ , x is $\mathbb{R}^n$ and λ is in $\mathbb{R}^m$.

So, λ are the Lagrange; a λ are called Lagrange multiplier corresponding to the constraints. How many constraints we are having in this problem P? We are having m number of constraints. So, corresponding where we will be having m number of Lagrange multipliers in the Lagrange function.

So, the Lagrange function is a function of two unknowns x and λ , which may be defined as the objective function; the objective function is $f(x)$ here you see, objective function comes here. And the sum of $\lambda_i g_i$; i is from 1 to m because, there are m number of constraints.

So, this $\lambda_1, \lambda_2, \lambda_3$ up to λ_m ; these are called Lagrange multipliers. So, in j we can also write this problem as $f(x) + \lambda^T g(x)$; λ^T see λ is basically, λ_1, λ_2 up to λ_m , and g is basically g_1, g_2 up to g_m .

So, when we multiply these two then we get, $g_1 \lambda_1 + g_2 \lambda_2$ and so on up to $g_m \lambda_m$. So, in this way we can write we can write the Lagrange of a given non-linear programming problem.

(Refer Slide Time: 04:47)

Dual Problem

The dual of the problem (P) is given as:

$$\begin{aligned} & \text{Max } L(x, \lambda) \\ \text{s/t } & \nabla_x L(x, \lambda) = 0, \\ & \lambda \geq 0. \end{aligned}$$

This can be re-written as:

$$\begin{aligned} \text{(D) Max } & f(x) + \sum_{i=1}^m \lambda_i g_i(x) \\ \text{s/t } & \nabla f(x) + \sum_{i=1}^m \lambda_i \nabla g_i(x) = 0, \\ & \lambda_i \geq 0, \quad i = 1, 2, \dots, m. \end{aligned}$$

 4

Now, how can you write a dual of this problem? So, dual may be as, the dual of this problem P is given as we write maximizing of Lagrange function; subject to gradient respect to x of this Lagrange equal to 0; lambda greater than equal to 0.

So, this is how we can defined Lagrange we can define the dual of this problem P ok. Now, this dual this problem can be rewritten as see what is the Lagrange function? Lagrange function we have already seen. The Lagrange function is basically f x plus summation i from 1 to m lambda i g i ok.

So, this is Lagrange, this Lagrange will come here maximization of this subject to; now the gradient of this function this Lagrange respect to x. So, gradient of this respect to x it will come here. The gradient of this respect to x will come here equal to 0 and lambda i greater

than equal to 0 for all i . So, this is how we can write the dual of this problem P; then this dual is also called Wolfe phase dual ok.

(Refer Slide Time: 05:54)

If f, g_i ($i = 1, 2, \dots, m$) are convex differentiable functions, then the problem (P) becomes a convex programming problem and we denote it as (CP).

Weak Duality Theorem

Let x be feasible for (CP) and (u, λ) be feasible for (D). Then,

$$f(x) \geq f(u) + \sum_{i=1}^m \lambda_i g_i(u).$$

Corollary

Let $\bar{x}$ be feasible to (CP) and $(\bar{u}, \bar{\lambda})$ be feasible for (D). Further, let

$$f(\bar{x}) = f(\bar{u}) + \sum_{i=1}^m \bar{\lambda}_i g_i(\bar{u}).$$

Then, $\bar{x}$ is optimal for (CP) and $(\bar{u}, \bar{\lambda})$ is optimal for (D).

So, if we are calling two problem as a; if one problem the initial the first problem is called primal problem, and the second problem is called the dual problem. Now, there is some relation between these two, as I already told you that the optimality, condition optimality of one of the problem guarantee is the optimality of the other problem and vice versa.

So, there are some relations between these two and these are called duality relations. There are certain duality theorems you see; so what are those results? Let us first try to understand those results. So first is if f and g_i ; g_i for all i are convex differentiable functions, in this problem.

See, in this problem P if this f and all g_i 's are convex then, this problem is called convex programming problem. And now we denote this problem as CP ok. The problem P we are calling as CP. So, the first result is which we are calling as weak duality result it states that, if x is a feasible solution of CP and u, λ is feasible for problem D, which is a dual of this problem P of this problem CP then, this inequality always hold.

This inequality means the minimum value of the objective function of the primal problem P or CP is always greater than equal to the maximum value of the objective function I mean the value of the objective function of problem D.

(Refer Slide Time: 07:42)

$$f(x) \geq f(u) + \lambda^T g(u)$$

Proof: By the convexity of f at u , we have

$$f(x) - f(u) \geq (x-u)^T \nabla f(u)$$

$$= - (x-u)^T \sum_{j=1}^m \lambda_j \nabla g_j(u) \quad \text{--- (1)}$$

Again, by the convexity of g_j at u , we get

$$g_j(x) - g_j(u) \geq (x-u)^T \nabla g_j(u)$$

$$\sum_{j=1}^m \lambda_j (g_j(x) - g_j(u)) \geq \sum_{j=1}^m \lambda_j (x-u)^T \nabla g_j(u)$$

$$= - (x-u)^T \sum_{j=1}^m \lambda_j \nabla g_j(u)$$

$$= f(x) - f(u)$$

$$f(x) \geq f(u) + \sum_{j=1}^m \lambda_j (g_j(x) - g_j(u))$$

$$f(x) \geq f(u) + \sum_{j=1}^m \lambda_j g_j(x) - \sum_{j=1}^m \lambda_j g_j(u)$$

$$f(x) \geq f(u) + \sum_{j=1}^m \lambda_j g_j(x) \quad \text{since } g_j(u) \leq 0 \text{ and } \lambda_j \geq 0$$

(P) $\begin{cases} \min & f(x) \\ \text{s.t.} & g_j(x) \leq 0, j=1,2,\dots,m \end{cases}$

(D) $\begin{cases} \max & f(x) + \sum_{j=1}^m \lambda_j g_j(x) \\ \text{s.t.} & \nabla f(x) + \sum_{j=1}^m \lambda_j \nabla g_j(x) = 0, \\ & \lambda_j \geq 0, j=1,2,\dots,m \end{cases}$

So, how we got this result? So, let us try to understand. So, we are having two problems here. So, what is our primal problem? The primal problem is minimization of $f(x)$ subject to $g_j(x) \leq 0$

than equal to 0; j from 1 to m . And this problem if, f and g_j 's are convex for all j ; we are calling as CP.

And the problem D which is a dual of this problem CP is given by maximization of Lagrange function which is f^*x plus summation j from 1 to m λ_j $\nabla g_j(x)$ subject to the gradient of this should be 0; that means gradient of f^*x plus summation j from 1 to m λ_j $\nabla g_j(x)$ equal to 0; and λ_j greater than equal to 0 for all j .

So, this is this problem is D and this problem is CP. So, what is weak duality result? Weak duality result says that, if x is any feasible point of the problem CP and u, λ is any feasible point of the problem D then, f^*x is always greater than equal to $f^*u + \lambda^T \nabla g(u)$.

So, now we have we have to prove this. So, it is given to us that f is convex, and g_j for all j 's are convex; x is feasible for this problem and u, λ is feasible for this problem D. So, let us try to prove this result. So, since by the convexity of f at u , we have $f(x) - f(u) \geq (x - u)^T \nabla f(u)$.

This is why the convexity of f ; because f is a differentiable convex functions hence, this result will hold, that we have already discussed in our in the previous lectures. Now, since u is feasible for this problem D. So, you multiply both sides by $x - u$ transpose so, that means, this will be equal to $(x - u)^T \nabla f(u) + \sum_{j=1}^m \lambda_j (x - u)^T \nabla g_j(u) \leq 0$ ok.

This is because you see u, λ is feasible for this problem D. So, you multiply both sides by $x - u$ transpose; so, this quantity will be equal to the negative of $(x - u)^T \sum_{j=1}^m \lambda_j \nabla g_j(u)$. Now, again so say this inequality as inequality 1. So again, by the convexity of g_j at u , we have we get $g_j(x) - g_j(u) \geq (x - u)^T \nabla g_j(u)$.

(Refer Slide Time: 11:57)

Multiply by λ_j both sides of the above inequality,
 & sum up all the m - inequalities, we get

$$\sum_j \lambda_j g_j(x) - \sum_j \lambda_j g_j(u) \geq (x-u)^T \sum_j \lambda_j \nabla g_j(u) \quad \text{--- (2)}$$

from (1) & (2), we obtain

$$\begin{aligned} f(x) - f(u) &\geq \sum_j \lambda_j g_j(u) - \sum_j \lambda_j g_j(x) \\ &\geq \sum_j \lambda_j g_j(u) + 0 \\ \Rightarrow f(x) &\geq f(u) + \sum_j \lambda_j g_j(u) \quad \cdot \square \end{aligned}$$

So, multiply by λ_j both sides of the above constraint of the above inequality, and sum up all the m in equations inequalities, we get; so, now what we will obtain? Summation λ_j it is $\lambda_j g_j(x)$ it summation over j minus summation over j $\lambda_j g_j(u)$ is greater than equal to minus x minus u whole transpose summation j λ_j gradient of $g_j(u)$; this is suppose this is in equation 2.

Now, you can use this in equation because this side is less than equal to this side oh this is positive this is not negative; this is positive. So, now you from one and two see this side is less than equal to this side ok, and the negative of negative of this side is greater than equal to this side.

So, using 1, from 1 and 2 what we obtain? From 1 and 2 we get here we obtained this from this side it is $f(x) - f(u)$ is greater than equal to 0, so, you multiply both sides with minus 1. So, this factor will come before towards ok; axis feasible for this problem.

So, $g_j(x)$ will be less than equal to 0 for every j ok. So, negative of g_j will be greater than equal to 0 for all j and λ_j 's are non-negative. So, from this we will obtain that this quantity with negative sign is greater than equal to 0; so that means, it is greater than equal to $g_j \lambda_j g_j u$ plus 0 ok, because this because this is less than equal to 0; for every j and λ_j 's are non-negative.

So, when you multiply and sum it sum it up for all j ; so this quantity will be less than equal to 0 with negative it will be greater than equal to 0. So, what we obtain from here now it is $f(x)$ is greater than equal to $f(u)$ plus summation over j $\lambda_j g_j u$. So, hence we got the result. So, this is our weak duality results result. So, basically weak duality result is important to find out the bound of the problem; as the primal problem or the dual problem.

If there is any u or λ which is feasible for the problem D then, we can easily say that this value will be finite for that u and λ and $f(x)$ will always be greater than equal to that value. So, that will be helpful in finding out the bound of a given problem. So, the primal problem or the dual problem similarly if you know x as a feasible problem for the problem CP then, you know this value some finite value; then we can say that the objective function a dual problem will always be less than equal to that value.

So, this is helpful in finding out the bounds of the primal problem or the dual problem. Now, the next is now the next result from the weak duality result that if $\bar{x}$ is a feasible point of CP and $\bar{u}$ $\bar{\lambda}$ is feasible for D, and suppose the value of the objective function of the primal at $\bar{x}$ and the value of the dual problem at $\bar{u}$ $\bar{\lambda}$ both are equal; both coincides. Then, as far as the optimal solution of optimal solution for CP and $\bar{u}$ $\bar{\lambda}$ will be the optimal solution for problem.

(Refer Slide Time: 16:38)

The slide contains handwritten mathematical text. At the top, it states $f(\bar{x}) = f(\bar{u}) + \sum_j \bar{\lambda}_j g_j(\bar{u}) \rightarrow \text{Given}$. Below this, the proof begins with "Proof: let y be any feasible point of the problem (CP). we need to show that $f(\bar{x}) \leq f(y)$." It then references the "weak duality result" to show $f(y) \geq f(\bar{u}) + \sum_j \bar{\lambda}_j g_j(\bar{u}) = f(\bar{x})$. This leads to the conclusion $\Rightarrow f(\bar{x}) \leq f(y)$ and finally $\Rightarrow \bar{x}$ is the optimal solution of (CP). The slide has a blue header and footer with logos and a page number '3'.

$$f(\bar{x}) = f(\bar{u}) + \sum_j \bar{\lambda}_j g_j(\bar{u}) \rightarrow \text{Given}$$

Proof: let y be any feasible point of the problem (CP).
we need to show that $f(\bar{x}) \leq f(y)$.

By the weak duality result, we have

$$f(y) \geq f(\bar{u}) + \sum_j \bar{\lambda}_j g_j(\bar{u})$$
$$= f(\bar{x})$$
$$\Rightarrow f(\bar{x}) \leq f(y)$$
$$\Rightarrow \bar{x} \text{ is the optimal solution of (CP).}$$

So, the proof is again very easy to obtain see here what is given to us? It is given to us that $f(\bar{x})$ is equal to $f(\bar{u})$ plus summation over j $\bar{\lambda}_j g_j(\bar{u})$. So, it is given to us. And we have to show that $\bar{x}$ and $\bar{x}$ and $\bar{u}$ $\bar{\lambda}$ are nothing but the optimal solutions of the primal or dual problems.

So, if you want to show that $\bar{x}$ is an optimal solution or dual problem then, we need to show that $f(\bar{x})$ will be less than equal to $f(y)$ for any feasible y , 2 problem CP. So, let us try to prove this result proof let y be any feasible point of the problem CP ok. So, we need to show that $f(\bar{x})$ is less than equals to $f(y)$ ok; this we need to show.

So, now by the weak duality result, we have $f(y)$ is greater than equals to $f(\bar{u})$ plus summation over j $\bar{\lambda}_j g_j(\bar{u})$; since, y is feasible point for the any feasible point of the primal

problem and $\bar{u}, \bar{\lambda}$ is also a feasible point of the problem D; then by the weak duality result this inequality will hold ok.

And this quantity is nothing but is equal to $f(\bar{x})$. So, it is equal to $f(\bar{x})$. So, this implies $f(\bar{x})$ is always less than equals to $f(y)$ and hence, we can say that $\bar{x}$ is nothing but the optimal solution of the primal problem because, this value is always less than equal to $f(y)$ for any y ; for any feasible y so; that means, $\bar{x}$ is the optimal solution of the primal problem.

And similarly, if you want to show that $\bar{u}, \bar{\lambda}$ is an optimal solution or dual problem then, now so this implies $\bar{x}$ is the optimal solution of the CP.

(Refer Slide Time: 19:25)

Let (u, λ) be any feasible point of the problem (D).
 we need to show that $f(\bar{x}) + \sum_j \bar{\lambda}_j g_j(\bar{u}) \geq f(u) + \sum_j \lambda_j g_j(u)$.

By weak duality result, we have

$$f(\bar{x}) \geq f(u) + \sum_j \lambda_j g_j(u)$$

$$\Rightarrow f(\bar{x}) + \sum_j \bar{\lambda}_j g_j(\bar{u}) \geq f(u) + \sum_j \lambda_j g_j(u)$$

$$\Rightarrow (\bar{u}, \bar{\lambda}) \text{ is the optimal solution of (D).}$$

Now, let u, λ be any feasible point of the problem D ok. Now, we have to show that $\bar{u}, \bar{\lambda}$ is an optimal solution. That means, so we need to show that $f(\bar{u}) + \sum_j \bar{\lambda}_j g_j(\bar{u}) \geq f(u) + \sum_j \lambda_j g_j(u)$.

summation over j $\lambda_j \bar{g}_j u$ is greater than equal to $f u$ plus summation over j $\lambda_j g_j u$; because it is a maximization type problem.

So, again this is easy because, by the weak duality results, what we have? We have $f x$ bar is greater than equal to $f u$ plus summation over j $\lambda_j g_j u g_j u$; because x bar is the feasible point of the primal problem and u lambda is a feasible point of the dual problem.

So, this implies since, this is equal to because this is equal to this so we can replace this by this. So, this is this implies $f u$ bar plus summation over j $\lambda_j g_j u$ bar is greater than equals to $f u$ plus summation over j $\lambda_j g_j u$ bar $g_j u$. So, this implies u bar lambda bar u bar lambda bar is the optimal solution of D.

So, hence we have proved the result. So, in this way we can say that, if the optimum values of the primal and dual are equal then the points where they are equal are nothing but the optimal solutions of the respective problems.

(Refer Slide Time: 21:50)

Strong Duality Theorem

Let $\bar{x}$ be feasible to (CP) and the basic constraint qualification hold at $\bar{x}$. Then there exists $\bar{\lambda}$ such that $(\bar{x}, \bar{\lambda})$ is optimal to (D). Further, the optimal values of the two objective functions coincide.

So, next here is strong duality result with the state that, if $\bar{x}$ is the feasible point of CP and the basic constraint qualification hold at $\bar{x}$ then, there exists $\bar{\lambda}$ such that $\bar{x}, \bar{\lambda}$ is optimal to the problem D. Further, the optimum values of the two objectives coincide.

So, basically weak duality result is helpful in finding the bounds of the primal of the dual problems ok. And their strong duality result guarantees the optimal solution of the one problem if we have the optimal solution of the primal problem. If we have the optimal solution of primal problem then, we there exist an optimal solution in the dual problem and the value of the objective values of both are equal ok.

(Refer Slide Time: 22:33)

Dual of a QPP

Consider a QPP as follows:

$$\begin{aligned} \text{(QP) Min } & c^T x + \frac{1}{2} x^T Q x \\ \text{subject to } & Ax \leq b, \\ & x \geq 0 \end{aligned}$$

where A is an $m \times n$ matrix, $c, x \in \mathbb{R}^n$, $b \in \mathbb{R}^m$ and Q is an $n \times n$ symmetric positive semi-definite matrix.

So, now let us write to try to find that how we can write a dual of a QPP, quadratic programming problem. So, this is a Quadratic Programming Problem. So, how we can write a dual we already know that this is a QPP because, objective function is quadratic in nature and all constraints are linear. So, here A is an m cross n matrix, c and x belongs to $\mathbb{R}^n$, b belongs to $\mathbb{R}^m$ and Q is a n cross n symmetric positive semi definite matrix. So, again to write a dual we can first write the Lagrange of this function.

(Refer Slide Time: 23:09)

$$\begin{aligned}
 (QP) \quad & \text{Min} \quad c^T x + \frac{1}{2} x^T Q x \\
 \text{s.t} \quad & Ax \leq b \rightarrow Ax - b \leq 0 \rightarrow u \\
 & x \geq 0 \rightarrow -x \leq 0 \rightarrow v \\
 \\
 L(x, u, v) = & c^T x + \frac{1}{2} x^T Q x + u^T (Ax - b) \\
 & + v^T (-x) \\
 \text{Dual:} \\
 (QD) \quad & \text{Max} \quad L(x, u, v) \\
 \text{s.t} \quad & \nabla_x L = 0, \\
 & u \geq 0, v \geq 0
 \end{aligned}$$

So, what is the problem we are having? Problem is minimizing $c^T x$ plus $\frac{1}{2} x^T Q x$ subject to $Ax \leq b$ and $x \geq 0$. Now, this constraint can be re written as $Ax - b \leq 0$ and this constraint can be written as $-x \leq 0$. Let the that the Lagrange multipliers corresponding to these constraints are u , and let the Lagrange multiplier of these constraints are v .

So, L which is now a function of x , u and v can be written as, first is the objective function; objective function is what? $c^T x$ plus $\frac{1}{2} x^T Q x$ ok; plus now it is $u^T (Ax - b)$ and $v^T (-x)$. So, this was the Lagrange function of this problem QP, this problem is QP.

Now, how can we write a dual of this problem? The so, a dual of this problem will be D here QD can will be now, it is maximization of L x, u subject to gradient with respect to x of L will be 0 and u greater than equal to 0 and v greater than equal to 0; as we have already discussed the prop the dual of a given a NLP given non-linear problem will be nothing but, the Wolfe phase dual is nothing but, maximizing of the Lagrange function subject to gradient respect to x of L is 0.

And the Lagrange multipliers must be non-negative. So, now let us rewrite this problem. So, what will be QD now? It will be maximization of $\frac{1}{2} c^T x$; oh it is not $\frac{1}{2}$ it is c here. It is $c^T x$.

(Refer Slide Time: 25:12)

$$\begin{aligned}
 \text{(QD)} \quad & \text{Max} \quad c^T x + \frac{1}{2} x^T Q x + u^T (Ax - b) - v^T x \\
 \text{s.t.} \quad & c + Qx + A^T u - v = 0, \\
 & u \geq 0, \quad v \geq 0
 \end{aligned}$$

ok.

$$\begin{aligned}
 x^T c + x^T Q x + x^T A^T u - x^T v &= 0 \\
 u \geq 0, \quad v \geq 0.
 \end{aligned}$$

$$x^T v = (x^T v)^T = \underline{\underline{v^T x}}$$

So, it will be $c^T x + \frac{1}{2} x^T Q x + u^T A x - b^T x - v^T x$ subject to what are the conditions? So, you can verify from here subject to gradient respect to x . So, what will the gradient with respect to x ?

You differentiate this function with respect to x so, it will be $c + Q x$ because q is a symmetric matrix; otherwise it will be $q^T x$, but here $Q x$ is a symmetric matrix so Q^T would be Q ; plus it will be $A^T u$ and minus b equal to 0; v is equal to 0 ok.

And this u is non-negative and v is non-negative ok. Now, this can be rewritten as, now if you see if you multiply this equation by c^T by x^T so what will obtain? So, it will be $x^T c + x^T Q x + A^T u^T x - b^T x - v^T x$ equal to 0; and x and u and v non negative.

So, I am trying to like rewrite these equations these this problem. So, basically dual is this; but I am trying to write this problem in a simplified way. So, I can replace this quantity this is $x^T v$ which is same as $x^T v^T$ whole transpose because, this is a scalar quantity. So, this is equal to $v^T x$.

So, I can replace $v^T x$ from this equation to this. So, if I replace this if I replace this from here to this equation what will be what I will obtain finally? So, finally I will obtain, now you can see from here.

(Refer Slide Time: 27:41)

The dual of (QP) is formulated as:

$$\begin{aligned} \text{(QD) Max } & c^T x + \frac{1}{2} x^T Q x + u^T (Ax - b) - v^T x \\ \text{subject to } & c + Qx + A^T x - v = 0, \\ & u, v \geq 0 \end{aligned}$$

or

$$\begin{aligned} \text{(QD1) Max } & -\frac{1}{2} x^T Q x - u^T b \\ \text{subject to } & c + Qx + A^T u \geq 0, \\ & u \geq 0. \end{aligned}$$

So, this is a dual which we are already obtained. So, now you can replace v from this equation to this ok. So, if I replace this finally after simplification of this simple equation I will obtain this. Now, this is equal to v ; so I can write v as greater than equal to 0; so it will be greater than equal to 0. So, v is eliminated from the entire expression. So, now I can say that this is also the dual of this problem QP. This problem QP ok.

(Refer Slide Time: 28:18)

Problem:

Consider the following problem:

$$\begin{aligned} \text{(EP) Min } & (x_1 - 4)^2 + (x_2 - 6)^2 \\ \text{subject to } & 2x_1 - x_2 \leq 6, \\ & x_1 - x_2 \leq 2, \\ & x_1, x_2 \geq 0. \end{aligned}$$

(a) Find the dual of the problem (EP).

(b) Verify that $(x_1 = 0.8, x_2 = 4.4)$ and $(x_1 = 0.8, x_2 = 4.4, \lambda_1 = 3.2, \lambda_2 = 0)$ are the optimal solutions of (EP) and its dual respectively.

So, let us take a problem now. Suppose, you are having this QPP, and you want to write a dual of this QPP. So, how can you write?

(Refer Slide Time: 29:29)

$$\begin{aligned}
 \text{Min } f &= (x_1 - 4)^2 + (x_2 - 6)^2 \\
 \text{s.t. } & \left. \begin{aligned} 2x_1 - x_2 &\leq 6, \rightarrow u_1 \\ x_1 - x_2 &\leq 2, \rightarrow u_2 \\ x_1, x_2 &\geq 0 \end{aligned} \right\} \begin{aligned} x_1 &= 0.8 \\ x_2 &= 4.4 \end{aligned} \left. \vphantom{\begin{aligned} 2x_1 - x_2 &\leq 6, \rightarrow u_1 \\ x_1 - x_2 &\leq 2, \rightarrow u_2 \\ x_1, x_2 &\geq 0 \end{aligned}} \right\} f = 12.8
 \end{aligned}$$

$$\begin{aligned}
 \text{Max } g &= (x_1 - 4)^2 + (x_2 - 6)^2 + u_1(2x_1 - x_2 - 6) + u_2(x_1 - x_2 - 2) - v_1x_1 - v_2x_2 \\
 \text{s.t. } & \left. \begin{aligned} 2(x_1 - 4) + 2u_1 + u_2 - v_1 &= 0, \\ 2(x_2 - 6) - u_1 - u_2 - v_2 &= 0, \\ u_1, u_2, v_1, v_2 &\geq 0. \end{aligned} \right\} \text{Dual.} \\
 & \left. \begin{aligned} x_1 &= 0.8 \\ x_2 &= 4.4 \\ u_1 &= 3.2 \\ u_2 &= v_1 = v_2 = 0 \end{aligned} \right\} g = 12.8
 \end{aligned}$$

So, what is the QPP now? It is minimization of x_1 minus 4 whole square plus x_2 minus 4 and 6 ok; it is 4 here; 6 here. Subject to what are the equations? The first equation is $2x_1$ minus x_2 less than equal to 6, and x_1 minus x_2 less than equal to 2, and x_1, x_2 non negative. So, this is the primal problem.

So, what we are dual of this problem? We have already seen, the dual will be nothing but, it will be x_1 minus 4 whole square plus or if you want to eliminate u then that will be nothing but, so you have to otherwise you have to transform; so anyway you can write in that way only; x_2 minus 6 whole square plus so that the Lagrange multiplier correspond to this is u_1 , for this is u_2 , for this is a v_1 and v_2 .

So, $u_1 2x_1$ minus x_2 minus 6 plus u_2 times x_1 minus x_2 minus 2 minus $v_1 x_1$ minus $v_2 x_2$ ok. Subject to now, take the gradient of this problem the gradient will be $2x_1$ minus 4; first

with respect to x_1 $2x_1 - 4$ it is $2u_1 + u_2 - v_1$ equal to 0, and it is $2x_2 - 6 - u_1 - u_2 - v_2$ equal to 0 ok; u_1, u_2, v_1, v_2 non negative.

Now, so these are dual of this problem. This is a dual ok. Now, at this point 0.8, 4.4. So, if you are taking x_1 as 0.8 and x_2 as 4.4. So, it is satisfying all the constraints this point is satisfying the constraint; and the objective value of this problem is suppose this objective value is f and this is suppose g the objective value coming out to be 12.8.

Now, if we take this problem then, here we take x_1 as 0.8, x_2 as 4.4 ok; and u_1 as 1.6, v_1, v_2, u_1, u_2 both all are 0. So, this is basically so λ_1 here given as 3.2 so it is 3.2.

Now, if you take this point, this point satisfying both the dual constraint all the dual constraints in fact, and the objective value at this point is also the same as f is also the g is also at this point is 12.8; you can verify very easily very easy you can verify because, when x_1 is 0.8 and x_2 is 4.4, so this is 0.

So, this is 0; u_2, v_1, v_2 are already 0. So, this whole quantity is 0; so we left with only this these two terms which are same as the; which is same as a two terms of f . So, this is nothing but, a same objective value.

So, hence we can say that since the value of the objective function at these two points coincide; so these are nothing but, the optimal solutions of the prog this problem and this problem respectively ok. So, in this way if you want to write out a dual of a given NLP; here for illustration I have taken quadratic a programming problem.

In general, if you are having any non-linear problem which is a convex programming problem then, though you can write the Wolfe phase dual in this manner. You have a given non-linear problem, minimization type subject to g_j 's less than equal to 0. You know you can add a dual as the maximization of a Lagrange function subject to gradient of Lagrange respect to x equal to 0 and all Lagrange multipliers greater than equal to 0. So, that is a general format of writing

a dual of a given non-linear programming problem. In the next lecture we will see that how we can find out hard margin classifier using duality theory so.

Thank you very much.
