Lecture – 05
Linear Transformations

Hello friends. So, welcome to the 5th lecture of this course. So, in this lecture we will talk about a very important concept of linear algebra; that is called Linear Transformation. So, believe me linear transformation is the most useful concept if you are doing machine learning.

(Refer Slide Time: 00:47)

Relevance in Machine Learning

- Linear transformations are used in both abstract mathematics, as well as computer science. Linear transformations within calculus are used as way of tracking change, also known as derivatives.
- Linear transformations are often used in machine learning applications. They are useful in the modeling of 2D and 3D animation, where an objects size and shape needs to be transformed from one viewing angle to the next.
- An object can be rotated and scaled within a space using a type of linear transformations known as geometric transformations.
- Linear transformations also used to project the data from one space to another. Sometimes, a dataset is not linearly separable in its original space, therefore we need to transform (project) the data in another space with different dimensions. This can be done either using 'linear transformation' or 'kernels'.

2

So, linear transformation are used in both abstract mathematics as well as in computer science. So, this concept is very very frequently used in many of the topics of computer science also. Even electrical engineering electronics etcetera.

So, linear transformations within calculus are used as a way of tracking change also known as derivative. So, if you want to define derivative from some \mathbb{R}^3 to \mathbb{R}^3 then you have to make use of linear transformation. So, linear transformations are often used in machine learning applications; they are useful in the modeling of 2D and 3D animations.

So, very much useful in graphics, animation. How? Because by applying a linear transformation you can change the object shape in a plane or in a space and you can see from one viewing angle to another viewing angle.

Moreover an object can be rotated and scaled within a space using a type of linear transformations known as geometric transformations. So, in this lecture we will see later the scaling and rotation linear transformation. Linear transformations also used to project the data from one space to another. Suppose the data of your classification problem is not linearly separable in its original space.

So, what you can do? You can project the data to some other space where it can be linearly separable. And you can make use of some of the linear classifier like linear SVM or simple perceptron type of classifiers to classify the complex data which is not linearly separable in original space.

(Refer Slide Time: 03:01)

Linear Transformation

Let V and W be vector spaces over a field F of dimensions n and m , respectively. A linear transformation is a mapping $T : V^{(n)}(F) \rightarrow W^{(m)}(F)$ such that

- (1) $T(v_1 + v_2) = T(v_1) + T(v_2) \forall v_1 \text{ and } v_2 \in V$
- (2) $T(\alpha v) = \alpha T(v) \forall v \in V \text{ and } \alpha \in F.$

Example:

- $T : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ such that
 $T(x_1, x_2) = (x_1, x_1 + x_2)$
- $T : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ such that
 $T(x_1, x_2, x_3) = (x_2, x_1, 0)$

Remarks:

- A linear map from T to itself is called a linear operator.
- A linear map from a vector space to underlying field is called a linear functional.

3

Let us come to the formal definition of linear transformation. So, let V and W be vector spaces over a field F of dimension n and m respectively. So, dimension of V is n dimension of W is m , a linear transformation is a mapping from vector space V to vector space W satisfying these two conditions. The first condition is additivity. That is T of v_1 plus v_2 equals to T of v_1 plus T of v_2 for all v_1, v_2 belongs to the vector space V .

So, here v_1 plus v_2 is a vector in vector space V while T of v_1 and T of v_2 are vector are vectors in vector space W . The second condition is homogeneity if you multiply a vector of v from α where α is a scalar from the field F then T of αv equals to α times T of v . For all v belongs to V vector space and α belongs to F .

So, if this mapping T satisfy these two conditions then we say that T is a linear transformation. Another name a popular name of linear transformation in some of the references you will find

as linear map or linear mapping. So, these are two examples of linear transformations T of \mathbb{R}^2 to \mathbb{R}^2 such that T of $x_1 \ x_2$ equals to x_1 comma x_1 plus x_2 . How to prove that it is a linear transformation?

(Refer Slide Time: 05:00)

$$\begin{aligned}
 T: \mathbb{R}^2 &\rightarrow \mathbb{R}^2 \text{ s.t. } T(x_1, x_2) = (x_1, x_1 + x_2) \\
 \text{Let } v_1 &= (x_1, x_2) \text{ and } v_2 = (y_1, y_2) \in V = \mathbb{R}^2(\mathbb{R}) \\
 T(v_1) &= T(x_1, x_2) = (x_1, x_1 + x_2) \\
 T(v_2) &= T(y_1, y_2) = (y_1, y_1 + y_2) \\
 T(v_1 + v_2) &= T(\underline{x_1 + y_1}, x_2 + y_2) = (x_1 + y_1, x_1 + y_1 + x_2 + y_2) \\
 &= T(v_1) + T(v_2) \checkmark \\
 T(\alpha v_1) &= T(\alpha x_1, \alpha x_2) = (\alpha x_1, \alpha(x_1 + x_2)) \\
 &= \alpha T(v_1) \checkmark \\
 T &\text{ is a linear Transformation.}
 \end{aligned}$$

So, we are having $T: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ such that T of $x_1 \ x_2$ equals to x_1 comma x_1 plus x_2 . So, let v_1 equals to $x_1 \ x_2$ and v_2 equals to $y_1 \ y_2$ belongs to V .

So, these are two arbitrary vector from the vector space V that is your \mathbb{R}^2 over the field of real number. So, again we are taking field as the field of real numbers, but this definition is true for any vector space over defined over any of the field. So, now, T of v_1 equals to T of $x_1 \ x_2$ which is x_1 comma x_1 plus x_2 .

Similarly, $T(v_2)$ equals to $T(y_1, y_2)$, it is y_1, y_2 . Now $T(v_1 + v_2)$ equals to $T(x_1 + y_1, x_2 + y_2)$ and this will become $x_1 + y_1$ that is your first component as per the definition of T and then sum of these 2 component.

So, $x_1 + y_1 + x_2 + y_2$. Now this equals to $T(v_1) + T(v_2)$. So, first condition of additivity is satisfied. Now $T(\alpha v_1)$ is $T(\alpha x_1, \alpha x_2)$ this becomes $\alpha x_1, \alpha x_2$ and this is $\alpha T(v_1)$.

Because $T(v_1)$ is x_1, x_2 and you are multiplying by α both the component. So, the second condition is also satisfied. So, hence T is a linear transformation. So, this is the working process for checking whether a transformation is linear or not. Similarly another example is T from \mathbb{R}^3 to \mathbb{R}^3 such that $T(x_1, x_2, x_3) = (x_2, x_1, 0)$.

So, what is the geometrical interpretation of a linear transformation. So, we apply this transformation to a vector and it is scaled or rotate or change the shape of that. So, if we are having a set of vectors for example, suppose I am having x_1, x_2 plane in \mathbb{R}^2 .

(Refer Slide Time: 09:08)

And in this I am having a square. So, let us say this is square of length 1. So, this is 0, 0 1, 0 1, 1 and 0, 1.

So, I apply a linear transformation T on it such that T of x_1 . So, T \mathbb{R}^2 to \mathbb{R}^2 T of $x_1 \times x_2$ equals to $2 \times 1 \ 2 \times 2$. So, now, I am having what this transformation is doing it is scaling each dimension by 2. So, then what will be the output? The in the output space $x_1 \times x_2$. So, we will apply this transformation on to this square. So, I will get another square where the length of each side is now 2 say it is scaling.

If I apply a linear transformation T $x_1 \times x_2$ equals to $x_1 \ 2 \times 2$, then what I will get? So, x_1 and x_2 . So, what this transformation is doing? It is not making any change in x_1 component; however, x_2 component is becoming twice. So, it will become a rectangle where this x_1

dimension remain same as 1; however, x 2 dimension become 2. If I am having a linear transformation let us say $T \times 1 \times 2$ equals to $x \ 1 \ 0$.

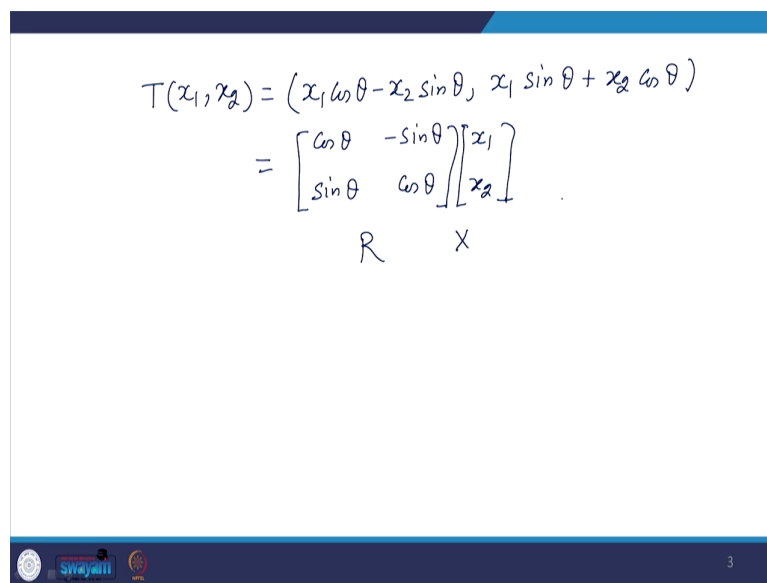

So, what this linear transformation is doing? First component will remain as such while the second component become zero. So, now, the output the result will become only a line from 0 to 1 on the x 1 axis. Similarly using the linear transformation I can rotate this square by an arbitrary angle in $x \ 1 \times 2$ plane.

For example, I will rotate it by 45 degree like this. So, what will be the linear transformation for this?

(Refer Slide Time: 12:20)

$$\begin{aligned} T(x_1, x_2) &= (x_1 \cos \theta - x_2 \sin \theta, x_1 \sin \theta + x_2 \cos \theta) \\ &= \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \end{aligned}$$

$R \quad X$

So, linear transformation for this will be T of $x_1 \times x_2$ will be $x_1 \cos \theta - x_2 \sin \theta$ and $x_1 \sin \theta + x_2 \cos \theta$. Basically, it is the rotation matrix in $x_2 \times x_1$ plane given by $\begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}$ and it is acting on $x_1 \times x_2$.

So, this is rotation matrix acting on the vector x where θ is the angle of rotation. Similarly we can define rotation matrices or rotation transformation in \mathbb{R}^3 . So, all these are geometrical interpretation of linear transformations. Some remarks, a linear transformation T from a vector space V to itself is called a linear operator. Similarly, a linear map or linear transformation from a vector space V to underlying field F is called a linear functional.

(Refer Slide Time: 13:46)

Some more examples:

Check which of the followings are linear map?

- ❶ $T : \mathbb{R}^2 \rightarrow \mathbb{R}^3$ s.t. $T(x_1, x_2) = (x_1 + x_2 + 1, 2x_1 - x_2, x_1 + x_2)$
- ❷ $T : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ s.t. $T(x_1, x_2) = (x_1 - x_2, 2x_1^2 - x_2^2)$
- ❸ $T : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ s.t. $T(x_1, x_2) = (x_1 - x_2, |x_1|)$
- ❹ $T : \mathbb{R}^2 \rightarrow \mathbb{R}^4$ s.t. $T(x_1, x_2) = (x_1 + x_2, x_1 - x_2, 2x_1 + x_2, 3x_1 - 4x_2)$
- ❺ $T : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ s.t. $T(x_1, x_2, x_3) = (x_3, x_2, x_1)$
- ❻ $T : M_2(\mathbb{R}) \rightarrow M_2(\mathbb{R})$ s.t. $T(A) = A^T$
- ❼ $T : M_2(\mathbb{R}) \rightarrow M_2(\mathbb{R})$ s.t. $T(A) = I + A$
- ❽ $T : M_2(\mathbb{R}) \rightarrow M_2(\mathbb{R})$ s.t. $T(A) = BAB^{-1}$ where B is an invertible matrix.

4

Some more examples; check which of the following are linear map. So, $T : \mathbb{R}^2 \rightarrow \mathbb{R}^3$ $T(x_1, x_2)$ is going to $x_1 + x_2 + 1, 2x_1 - x_2, x_1 + x_2$. So, the first condition we have to check the necessary condition to be a linear transformation. And what is the necessary

condition to be a linear transformation that? If you are having a linear transformation from vector space V to W . So, the zero vector of V map to the zero vector of W .

So, in this case, if you take $x_1 = 0, x_2 = 0$, it is going to $1 \ 0 \ 0$. So, it is not a linear transformation because zero vector is not going to zero vector. If you take this T of $x_1 \ x_2$ equals to x_1 minus x_2 $2x_1^2 - x_2^2$ again it is not a linear transformation. Because, additivity condition will fail here. So, for if you want to check it.

(Refer Slide Time: 15:04)

$$\begin{aligned}
 T(x_1, x_2) &= (x_1 - x_2, 2x_1^2 - x_2^2) \\
 (1, 1) \text{ and } (2, 2) &\text{ in } \mathbb{R}^2 \\
 T(1, 1) &= (0, 1) \quad \left| \quad T(3, 3) = (0, 9) \right. \\
 T(2, 2) &= (0, 4) \\
 T((1, 1) + (2, 2)) &\neq T(1, 1) + T(2, 2)
 \end{aligned}$$

So, I am having T of $x_1 \ x_2$ going to x_1 minus x_2 $2x_1^2 - x_2^2$. So, take 2 vectors, let us say $1 \ 1$ and $2 \ 2$ in \mathbb{R}^2 . So, T of $1 \ 1$ is going to 0 and 1 . T of $2 \ 2$ is going to 0 and 4 while T of $3 \ 3$ that is the sum of $1 \ 1$ and $2 \ 2$ is going to $0 \ 9$.

So, simply T of $\begin{pmatrix} 1 & 1 \\ 2 & 2 \end{pmatrix}$ which is $\begin{pmatrix} 0 & 9 \end{pmatrix}$ not equals to T of $\begin{pmatrix} 1 & 1 \\ 2 & 2 \end{pmatrix}$ plus T of $\begin{pmatrix} 1 & 1 \\ 2 & 2 \end{pmatrix}$. Hence T is not a linear transformation. Similarly you can check about this. So, due to this modulus, absolute value of x it is not a linear transformation.

While you can check that it will make a linear transformation, then this will make a linear transformation it will make a linear transformation; however, this 1 will not make a linear transformation. Why? Because 0 matrix here will go to identity 0 matrix should go to 0 matrix. So, in that way you can have all these checks whether a given transformation is linear or not.

(Refer Slide Time: 17:07)

The matrix of a linear map

Suppose $V(F)$ and $W(F)$ are finite dimensional vector spaces with bases $\{v_1, v_2, \dots, v_n\}$ and $\{w_1, w_2, \dots, w_m\}$ respectively. Let $T : V \rightarrow W$ be a linear map. Then the matrix of T , with entries $a_{ij} \in F$ is defined by

$$T(v_j) = a_{1j}w_1 + a_{2j}w_2 + \dots + a_{mj}w_m$$

for $j = 1, 2, 3, \dots, n$

It shows that the j^{th} column of the matrix A of linear map T consists of the coordinates of $T(v_j)$ in the chosen basis for W .

Conversely, every matrix $A \in \mathbb{R}^{m \times n}$ induced a linear map $T : \mathbb{R}^n \rightarrow \mathbb{R}^m$ given by

$$T(v) = Av$$

5

Now, every linear transformation is a matrix and every matrix is a linear transformation. So, what I want to say; linear transformation is nothing they are matrices only. So, how to find out

the matrix corresponding to a linear transformation first of all a linear transformation is from a vector space to another vector space.

So, you have to decide the basis relative to what basis you want to find out the associated matrix. So, how to do it suppose V and W are finite dimensional vector spaces with over the field F with basis v_1, v_2, \dots, v_n . So, dimension of V is n and dimension of W here is m and basis is w_1, w_2, \dots, w_m . T from V to W be a linear transformation, then the matrix of T with entries a_{ij} belongs to F some of the entry of the matrix will come from the field F is defined by for any basis vector v_j here T of v_j will be $a_{1j}w_1 + a_{2j}w_2 + \dots + a_{mj}w_m$.

So, what first you have to take the basis vector from this vector space v . You have to find out it is image where it is mapping to space in W and then you have to write that particular vector as the linear combination of w_1, w_2, \dots, w_m . Then the coordinates $a_{1j}, a_{2j}, \dots, a_{mj}$ will give the j th column of the associated matrix A .

(Refer Slide Time: 19:05)

Examples of matrix of a linear map

* Consider a linear map $T : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ defined by $T(x_1, x_2) = (2x_1 - 7x_2, 4x_1 + 3x_2)$.

Find the matrix representation of T relative to basis $B = \{(1,3), (2,5)\}$.

Solution: $T(1,3) = (-19,13) = a_{11}(1,3) + a_{21}(2,5)$

$$T(2,5) = (-31,23) = a_{12}(1,3) + a_{22}(2,5)$$

Gives $a_{11} = 121$; $a_{12} = 201$;

$a_{21} = -70$; $a_{22} = -116$

$$\text{Hence } A = \begin{pmatrix} 121 & 201 \\ -70 & -116 \end{pmatrix}$$

Suppose you are having a linear transformation from \mathbb{R}^2 to \mathbb{R}^2 defined by T of $x_1 \times x_2$ equals to $2x_1 - 7x_2$ comma $4x_1 + 3x_2$. Find a matrix representation of T relative to basis B given by the vectors $(1,3)$ and $(2,5)$.

So, first I will check the image of $(1,3)$ under T . So, T of $(1,3)$ will become $(-19,13)$. Now this vector I will write as the linear combination again of the basis of \mathbb{R}^2 . Here basis are same for both the vector space, it may be different in some of the examples. So, $a_{11}(1,3) + a_{21}(2,5)$. So, it will give the first column of the associated matrix A .

Similarly, $T(2,5)$ is $(-31,23)$. So, $a_{12}(1,3) + a_{22}(2,5)$. So, by solving these 2 I will get a_{11} as 121, a_{12} as 201, a_{21} as -70 and a_{22} as -116 . Hence the matrix A is $\begin{pmatrix} 121 & 201 \\ -70 & -116 \end{pmatrix}$. So, in that way you can find out the matrix representation of a given linear transformation.

(Refer Slide Time: 20:36)

Nullspace and Range of a linear map

Let $T : V \rightarrow W$ be a linear map. Then the nullspace of T is defined as

$$\text{null}(T) = \{v \in V \mid T(v) = 0\}$$

and the range of T is defined as

$$\text{range}(T) = \{w \in W \mid \exists v \in V \text{ s.t. } T(v) = w\}$$

Remarks:

- Nullspace of T is also called kernel of T denoted by $(\ker(T))$.
- $\text{Null}(T)$ is a subspace of V .
- $\text{Range}(T)$ is a subspace of W .
- The dimension of $\text{Null}(T)$ is called nullity of T .
- The dimension of $\text{Range}(T)$ is called rank of T .

7

Similarly, if you are having a matrix; how to find corresponding linear transformation?

(Refer Slide Time: 20:44)

$$A = \begin{bmatrix} 2 & 1 \\ 4 & 3 \end{bmatrix}$$

$$T(x_1, x_2) = \begin{bmatrix} 2 & 1 \\ 4 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = (2x_1 + x_2, 4x_1 + 3x_2)$$

$$T: \mathbb{R}^2 \rightarrow \mathbb{R}^2$$

$$T: \mathbb{R}^n \rightarrow \mathbb{R}^m \rightarrow \left[\begin{array}{c} \\ \\ \end{array} \right]_{m \times n}$$

So, let us say you are having a matrix A equals to $\begin{bmatrix} 2 & 1 \\ 4 & 3 \end{bmatrix}$, then the linear transformation representation of this corresponding to it is relative to the standard basis will become $\begin{bmatrix} 2 & 1 \\ 4 & 3 \end{bmatrix} \times 1 \times 2$. So, it will become 2×1 plus $x_2 \times 4$ plus $3 \times x_2$.

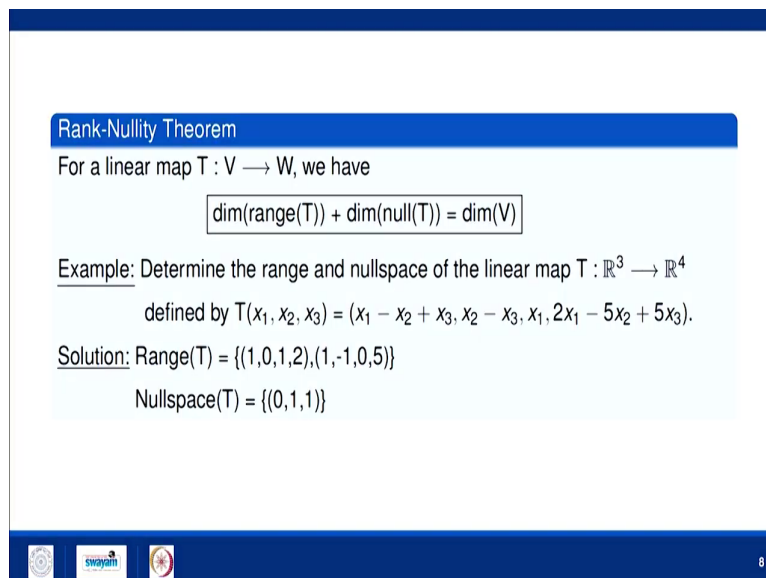

So, this is the linear transformation from $T: \mathbb{R}^2 \rightarrow \mathbb{R}^2$. So, if you are having a linear transformation from \mathbb{R}^n to \mathbb{R}^m , then matrix representation will be of a m by n matrix. So, this times this one you this you have to remember. Next, I am defining two important subspaces those are associated with linear transformations.

So, let $T: V \rightarrow W$ be a linear map, then the null space of T is defined as all vectors V belongs to this vector space V such that the image of v under T is 0 ; that is 0 vector of W . So, all those vectors from the vector space V those are mapped to the zero vector of W will come in null space of T . Hence and you can check very easily that this null space of T is a subspace of V .

The range space of T is all vectors w belongs to this vector space W such that there exists v belongs to V such that $T v$ equals to w . And you can easily verify that this range space or range of T is a subspace of W .

Null space of T also called kernel of T denoted by kernel of T . As I told you null space of T is a subspace of, range space of T is a subspace of W . So, the dimension of that null space is called nullity of T . Similarly, the dimension of range of t is called the rank of T .

(Refer Slide Time: 23:23)

Rank-Nullity Theorem

For a linear map $T : V \rightarrow W$, we have

$$\dim(\text{range}(T)) + \dim(\text{null}(T)) = \dim(V)$$

Example: Determine the range and nullspace of the linear map $T : \mathbb{R}^3 \rightarrow \mathbb{R}^4$ defined by $T(x_1, x_2, x_3) = (x_1 - x_2 + x_3, x_2 - x_3, x_1, 2x_1 - 5x_2 + 5x_3)$.

Solution: $\text{Range}(T) = \{(1, 0, 1, 2), (1, -1, 0, 5)\}$

$\text{Nullspace}(T) = \{(0, 1, 1)\}$

8

We are having a very important result here. So, for a linear transformation T which is defined from V to W . We have the dimension of range of T that is the rank of T plus dimension of null space of T ; that is nullity of T equals to dimension of this vector space V .

So, let us take an example, how to find out range space and null space of a linear transformation. So, determine the range and null space of the linear map which is from \mathbb{R}^3 to \mathbb{R}^4 and here field is the field of real numbers defined by T of $x_1 \times 2 \times x_3$ is going to x_1 minus x_2 plus $x_3 \times 2$ minus $x_3 \times 1$ and $2 \times x_1$ minus $5 \times x_2$ plus $5 \times x_3$.

(Refer Slide Time: 24:24)

$$\begin{aligned}
 &T: \mathbb{R}^3 \rightarrow \mathbb{R}^4 \text{ such that} \\
 &T(x_1, x_2, x_3) = (x_1 - x_2 + x_3, x_2 - x_3, x_1, 2x_1 - 5x_2 + 5x_3) \\
 &\text{Range}(T): \quad T(1, 0, 0) = (1, 0, 1, 2) \quad \checkmark \\
 &\quad \quad \quad T(0, 1, 0) = (-1, 1, 0, -5) \quad \checkmark \\
 &\quad \quad \quad T(0, 0, 1) = (1, -1, 0, 5) \quad \checkmark \\
 &\quad \quad \quad \text{Range}(T) = L\{(1, 0, 1, 2), (-1, 1, 0, -5)\} \\
 &\quad \quad \quad \text{Rank}(T) = 2 \\
 &\text{Null}(T): \{x \mid T(x) = 0\} \Rightarrow x_2 = x_1 + x_3; x_3 = x_3; x_1 = 0 \\
 &\quad \quad \quad \{x_1, x_2, x_3\} = \{0, x_1 + x_3, x_3\} \\
 &\quad \quad \quad \{0, x_2, x_3\} \Rightarrow \{0, 1, 1\} \quad ; \quad \text{Nullity}(T) = 1
 \end{aligned}$$

So, let us do it. So, I am having a mapping $T: \mathbb{R}^3 \rightarrow \mathbb{R}^4$ such that T of x_1, x_2, x_3 equals to x_1 minus x_2 plus $x_3 \times 2$ minus $x_3 \times 1$ and then $2 \times x_1$ minus $5 \times x_2$ plus $5 \times x_3$. So, first we will find out the range of T . So, for finding the range of T ; what I will take? I will take the standard basis of \mathbb{R}^3 and I will check where this standard basis is mapping.

So, first take the standard basis of \mathbb{R}^3 . So, $T(1, 0, 0)$ is mapping to $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$ and 2. Now take another vector of the standard basis of \mathbb{R}^3 ; $(0, 1, 0)$ it is going to $\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}$ from here 0 and then minus 5. Now, take the vector $(0, 0, 1)$.

So, $(0, 0, 1)$ will go to $\begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}$ and 5. Now, if you see these 3 vectors these 2 vectors are ld. Just this vector is minus 1 times this 1. And as I told you that in the basis of a sub space we include only.

Student: (Refer Time: 26:37).

Linearly independent vectors. So, here range of T will be linearly spanned by the vectors $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$ 2 and $\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}$ minus 5.

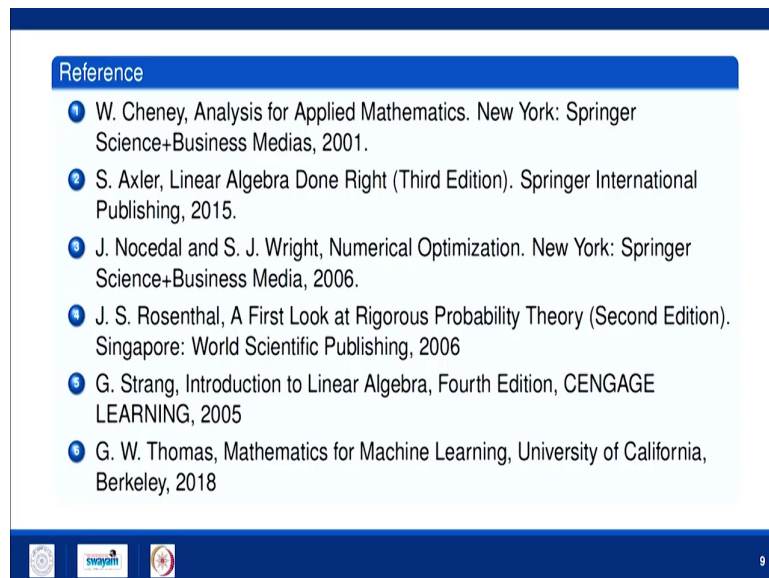

Hence rank of T is 2. Similarly, we have to find out null space. So, null space of T is all vectors X such that $TX = 0$. So, it is giving me $x_1 - x_2 + x_3 = 0$. So, from here I can write $x_2 = x_1 + x_3$. This equals to 0 gives me $x_2 = x_3$. x_1 is 0 from here and finally, the last 1 is giving me $5x_2 = 2x_1 + 5x_3$. So, $x_2 = x_3$ gives me $x_1 = 0$. So, $5x_2 = 5x_3$ because $x_1 = 0$ here. So, what I will get null space of v is x_1, x_2, x_3, x_4 such that all these are individually 0.

So, from here, what I will be having $x_1 = 0, x_2$ and then x_3 is sorry null space will come to the \mathbb{R}^3 . So, x_1, x_2, x_3 such that all these 4 equations equals to 0. So, x_2 this give me the range as $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$. So, null space of T is spanned by the vector $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$. Hence nullity of T equals to 1 because we are having only 1 vector in the basis of null space of T .

So, rank is 2, nullity is 1, rank plus nullity equals to 2 plus 1 3 that is the dimension of this vector space hence we are verifying the.

Student: Rank nullity.

Rank nullity theorem. So, in this lecture, we have learned very important concept of linear algebra. In the next lecture; we will see some more properties of linear transformation. These are the references. I hope you have enjoyed this lecture.

Thank you very much.
