Linear Transformations - Part 3

In the last lecture, we saw several examples of linear transformations. We shall now continue to study the structure of linear transformations, the answers to many of the questions that we raised lies in the study of the structure of a linear transformations.

(Refer Slide Time: 00:37)

Let us now consider a vector space V and a vector space W , both are vector spaces over a field F and recall that a transformation from V to W is called a Linear Transformation, if it preserve the basic algebraic operation in the vector spaces.

(Refer Slide Time: 01:09)

The screenshot shows a digital whiteboard with the following content:

- Handwritten text: "is called a l.t."
- Equation: $T(x+y) = T(x) + T(y) \forall x, y \in V,$
- Text: "and"
- Equation: $T(\alpha x) = \alpha T(x) \forall \alpha \in F \wedge \forall x \in V$
- Section header: A simple property of a l.t
- Equation: $T(\theta_V) = \theta_W$

The slide also features a video feed of a lecturer in the bottom right corner and a Windows Journal interface at the top.

If it preserves addition T of x plus y is T of x plus T of y for every x, y in V and it preserves scalar multiplication, T of αx is αT of x for every α in F and for every x in V . Such a Linear Transformations is going to hold the key for our studies on various questions that we raised and important property that we have observed a very simple, but important property. So, let us note that a simple property of a Linear Transformations which we saw last time was that if we take θ_V , the 0 vector in the V space T always maps it to the 0 vectors in the W space.

(Refer Slide Time: 02:14)

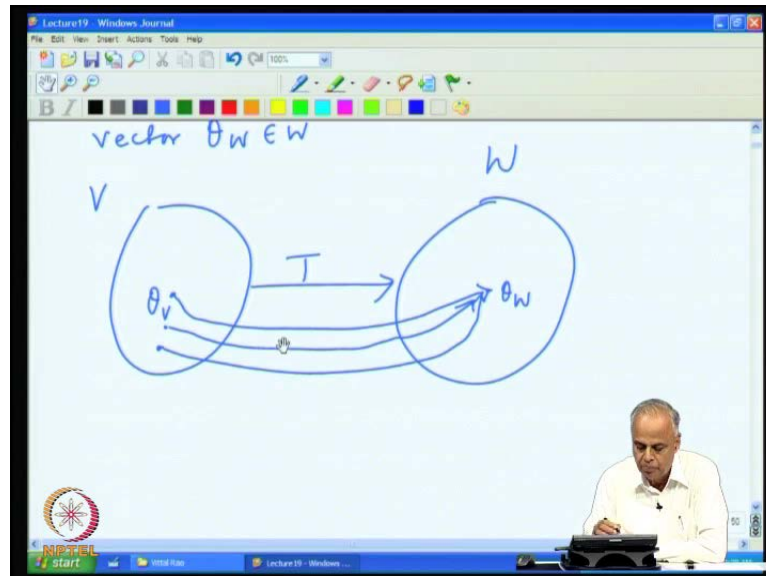

The screenshot shows a digital whiteboard with the following content:

- Equation: $T(\alpha x) = \alpha T(x) \forall \alpha \in F \wedge \forall x \in V$
- Section header: A simple property of a l.t
- Equation: $T(\theta_V) = \theta_W$
- Text: "A l.t. always maps the zero vector $\theta_V \in V$ to the zero vector $\theta_W \in W$ "

The slide also features a video feed of a lecturer in the bottom right corner and a Windows Journal interface at the top.

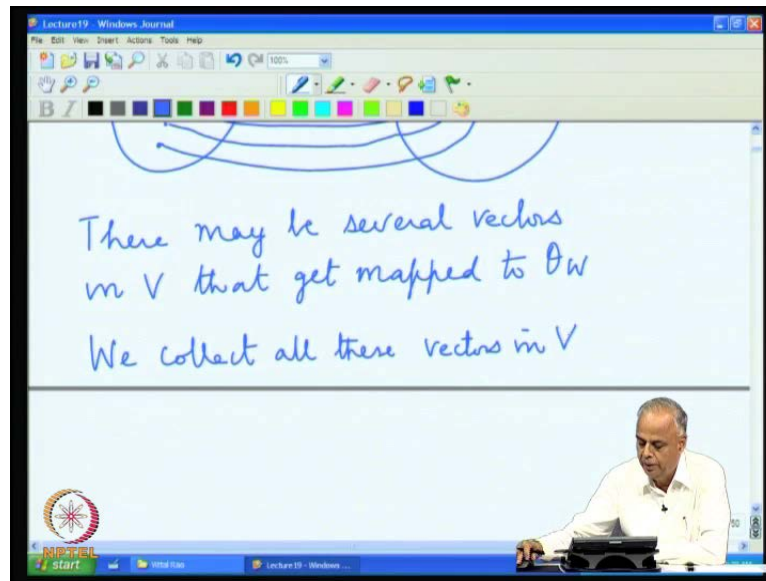

So, a Linear Transformation always maps the zero vector θ_V in V to the zero vector θ_W in W .

(Refer Slide Time: 02:40)

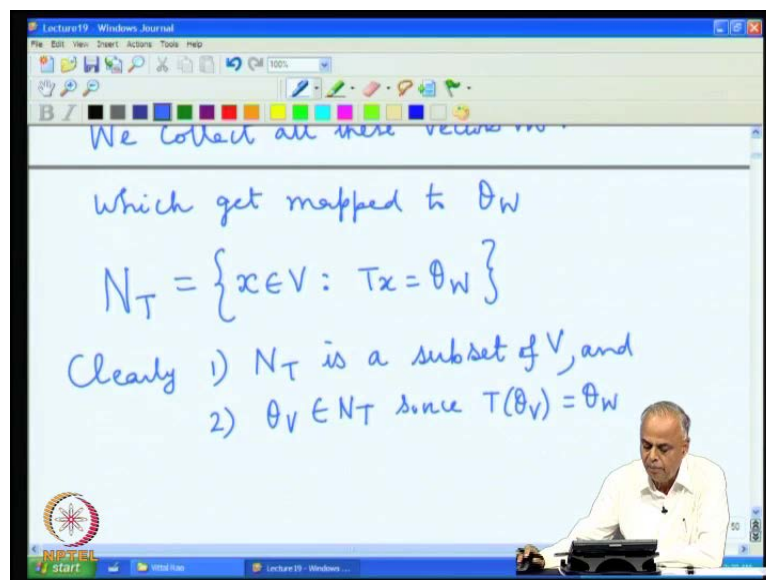

So, what does that mean? We have the vector space V and vector space W and T is the transformation that is taken V vectors into W vectors. What the above property says is, θ_V is a vector in V and θ_W is a vector in W , θ_V is the 0 vector in V , θ_W is the 0 vector in W , T pulls along this 0 and then maps into that 0 this is a typical property of Linear Transformations. Now, it may so happen that some other vector in V may also get pulled to the 0 vector, there may be another vector which get pulled to 0 vectors. In other words, there may be a lot of vectors in V which are all going to get focused towards θ_W , so all of them are going to be focused towards θ_W by this lens T . So, we collect these vectors which are going to be focused to θ_W .

(Refer Slide Time: 03:53)

So, there may be several vectors in V that get mapped to the 0 vector in W , in addition to the θ_V which we already know gets mapped to the θ_W . We collect all these vectors in V .

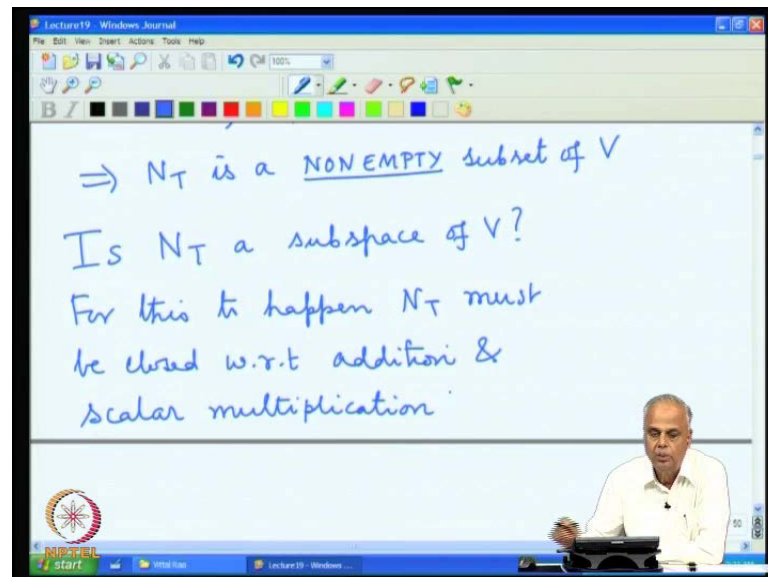

(Refer Slide Time: 04:32)

Which get mapped to 0 the 0 vector under the map T , so we denote this collection by N_T . So, N_T is the collection of all the vectors in V such that, they get mapped to the 0 vector. Now clearly, the first thing we observe is that N_T is a collection of vectors from V having certain specific property.

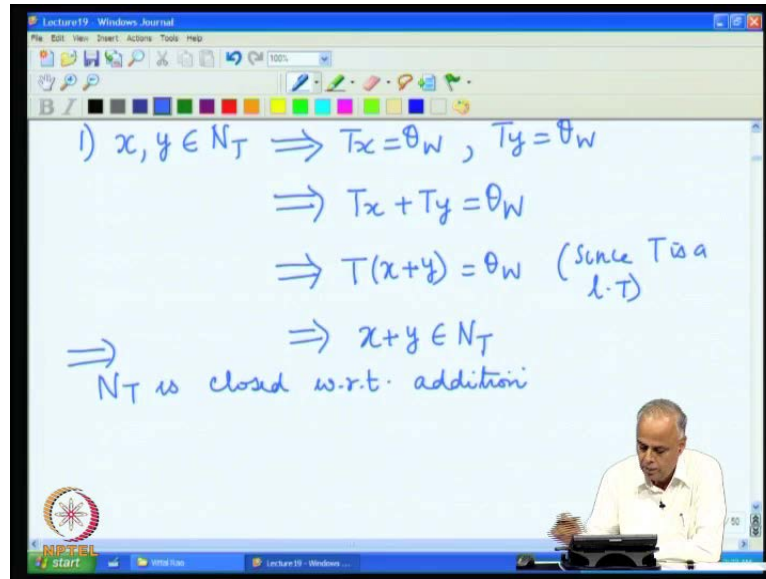

Therefore, a priori they are all vectors in V therefore, N_T is a subset of V (no audio from 05:16 to 05:22) and the second trivial thing that we know is that the 0 vector of V is certainly in N_T because the 0 vector get mapped to the 0 vector. Two, θV belongs to N_T , since T of θV equal to θW .

(Refer Slide Time: 05:46)

And therefore, N_T is a non empty subset of V because at least one vector namely θV which belongs to N_T . Now whenever we have a non empty subset of a vector space, the natural question that we ask is whether that is a sub space, so is N_T a subspace of V ? This always whenever there is a non empty **subspace of a vector** subset of vector space, we are always interested in knowing whether it is a subspace. In order to make sure that N_T is a subspace, we must make sure that N_T is closed with respect to the two basic operation of the vector space. So, for this to happen N_T must be closed with respect to addition and scalar multiplication that is the major requirement for any subset to get **qualification** qualified as a subspace. So, let us verify whether N_T is closed under these two operations.

(Refer Slide Time: 07:18)

So, let us first check with addition suppose we have two vectors in N_T , we want to know whether their sum will also be in N_T . Now all we know at present is that x and y are in N_T , but N_T is the collection of all those vectors which are mapped to the 0 vector and therefore, Tx must be the 0 vector that means x must be mapped to the 0 vector and Ty must be the 0 vector because x and y are in N_T and therefore, they map to the 0 vector. That says I can add the two and I will get equal to θ_W plus θ_W , the 0 vector plus the 0 vector is the 0 vector itself.

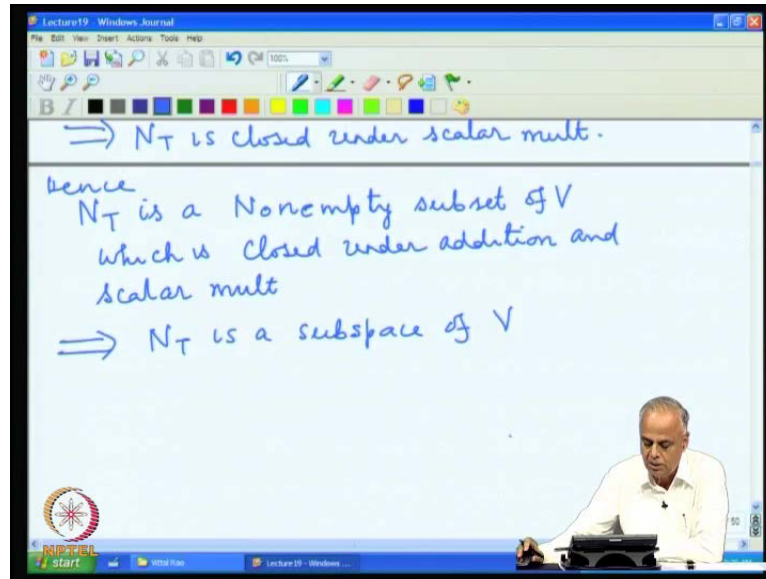

Now, we know that T is a Linear Transformation therefore, T preserves addition and hence $T(x+y)$ is the same as $Tx + Ty$; $Tx + Ty$ is the same as $T(x+y)$, that says this is because T is a Linear Transformation, we know T preserves addition. That says the vector $x+y$ is also getting mapped to the 0 vector and hence, $x+y$ also belongs to N_T . So, thus x and y belong to N_T mean $x+y$ belong to N_T hence, N_T the whole thing implies N_T is closed with respect to addition. The next thing we have to verify is whether N_T is closed with respect to scalar multiplication.

(Refer Slide Time: 09:08)

1) $x, y \in N_T \Rightarrow Tx = \theta_W, Ty = \theta_W$
 $\Rightarrow Tx + Ty = \theta_W$
 $\Rightarrow T(x+y) = \theta_W$ (since T is a l.T)
 $\Rightarrow x+y \in N_T$
 $\Rightarrow N_T$ is closed w.r.t. addition

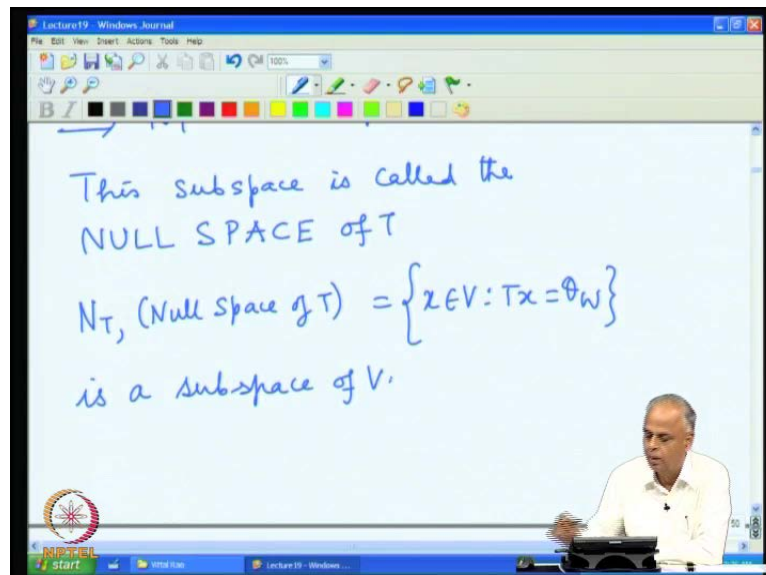

So, let us take a vector x in N_T what does that mean? We want to verify that it is closed with respect to scalar multiplication, that means when we multiply x by any scalar, the resulting vector must also be in N_T . Now first of all, we given x is in N_T this means T carries x to the 0 vector, that is the qualification for being in N_T , and if that is so for any scalar if I multiply both side by α , I get $\alpha \theta_W$ which is θ_W , when the 0 vector is multiplied by any scalar we get the 0 vector. Now since T is linear, T of αx is same as α of Tx , because T preserves scalar multiplication, so αTx is same as T of αx , since T is a Linear Transformations. So, that says vector αx is going to carry over to the 0 vector, and hence αx qualifies to be in N_T .

(Refer Slide Time: 10:24)

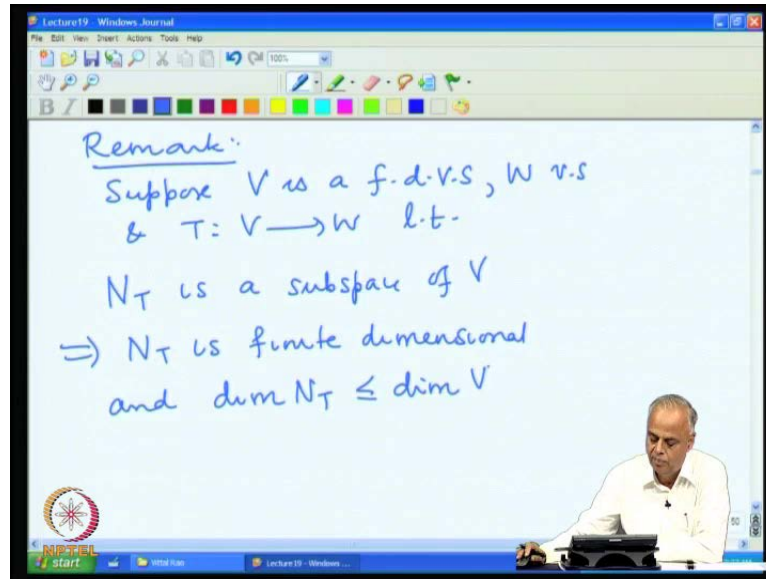

So, this says N_T is closed under scalar multiplication. Therefore, N_T so what are the various properties we observed? N_T is... So, hence N_T is first of all, a non empty subset of V which is closed under addition and scalar multiplication, and that makes it a subspace. So, N_T is a subspace of V .

(Refer Slide Time: 11:30)

This subspace is called the Null space vectors which get nullified Null space of T , so we have N_T is called Null space of T is the set of all vectors in V such that, Tx equal to 0_W and this is subspace of V . (no audio from 12:05 to 12:12)

(Refer Slide Time: 12:14)

Remark:
Suppose V is a f.d.v.s, W v.s
& $T: V \rightarrow W$ l.t.
 N_T is a subspace of V
 $\Rightarrow N_T$ is finite dimensional
and $\dim N_T \leq \dim V$

So, make one simple observation suppose, V is a finite dimensional vector space and T maps V to W and W is a vector space, we do not know whether it is finite or infinite dimensional space. So, it is some vector space and as a Linear Transformations; T mapping V to W is a Linear Transformations. Now, N_T is a subspace of V and V is a finite dimensional space, so we observed that any subspace of a finite dimensional vector space must be finite dimensional and its dimension should be less than or equal to the dimension of the full space and hence, we get N_T is finite dimensional and dimension of N_T is less than or equal to dimension of V because it is a part of V . This dimension is called the nullity of T .

(Refer Slide Time: 13:38)

N_T is a subspace of V
 $\Rightarrow N_T$ is finite dimensional
and $\dim N_T \leq \dim V$
This $\dim N_T$ Nullity of T and
is denoted by ν_T
 $\nu_T = \dim N_T$

And is denoted by the nu of T, so what do we have? nu of T is dimension of N_T where N_T is the Null space, so the nullity of Linear Transformations is just the dimension of the Null space of T. So, now we have collected all the vectors which are focused to 0 and then we have studied them and we find that they form a subspace and that subspace is called the null space and its dimension is called the nullity.

(Refer Slide Time: 14:20)

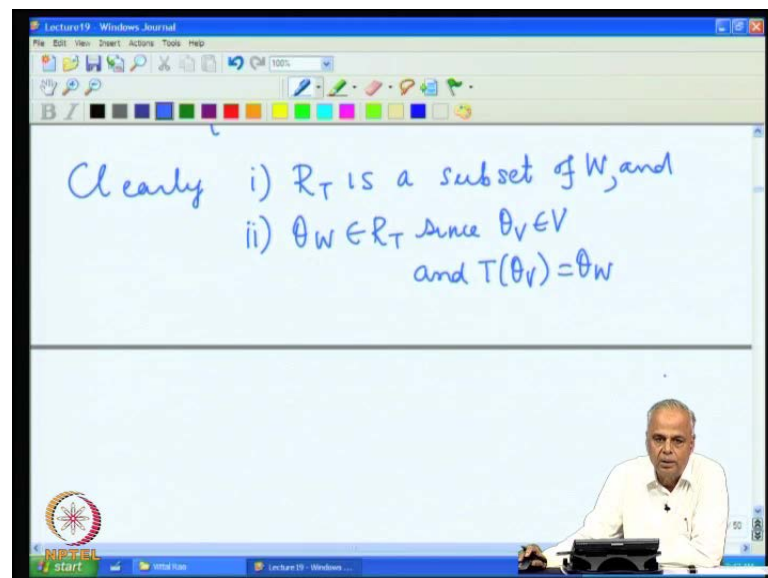

$R_T = \{y \in W : \exists x \in V \text{ such that } Tx = y\}$

Now let us look at again the transformation we have V , we have W and T transforms V vectors to W , now we have say this is N_T , that is all the vectors here are focused to W ;

All the vectors in this portion are going to be focused to W . The 0 vector in W now, if I take any vector that is not in $N(T)$, it will now get focus to elsewhere. This one may be focused somewhere. So, now therefore, we see that W is one focal point and there may be other focal points, that mean the other points in W where the image of a vector at V may come and form, we collect all these focal points.

So, we now look at the set $R(T)$ which is the collection of all these focal points; these focal points will be in W ; if a points in W we are trying to see where they come and fall. These are points in W such that, somebody comes and falls there is unique comes here under T , that is there exist a x in V such that the image of x under T is y . So, y is the focal point for x then he is take into $R(T)$, if y is not the focal point for anybody, it is not going to be in $R(T)$. So, $R(T)$ is the collection of all such y for which there is a pre image x such that $T(x) = y$, we also say that why the $R(T)$ is the collection of all the values taken by the function T ? T of x is the value of that function at the point x , so y is the value of the function at the point x . We are collecting all the possible values that the function T takes.

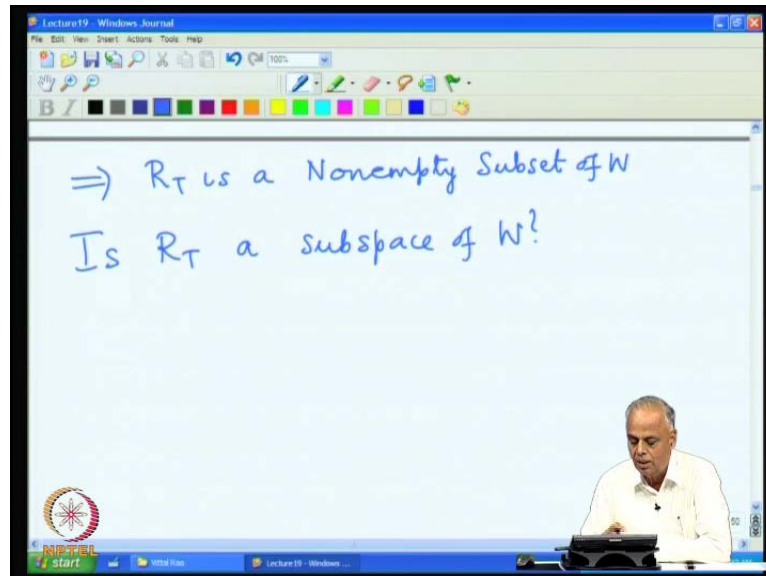

(Refer Slide Time: 16:37)

Now clearly, since this is a collection of vectors in W with certain specific property it is the subset of W . $R(T)$ is a subset of W and we have already seen, that 0_V goes to 0_W therefore, the 0_W is the one of the values taken by T . So, 0_W belongs to

R_T since, θV belongs to V and value of T at θV is precisely θW . So, there is at least one point in R_T therefore, R_T is a non empty subset of W .

(Refer Slide Time: 17:32)

So, that implies R_T is a non empty subset of W and as we look in the case of N_T , whenever we have a non empty subset vector space; we always interested in knowing whether it is a subspace. So, is R_T a subspace of W ? It can be a subspace of W because it is a subset of W . Once again, in order to check whether it is a subspace of W or not, there are two properties that we have to check, whether it is closed under addition and whether it is closed under scalar multiplication.

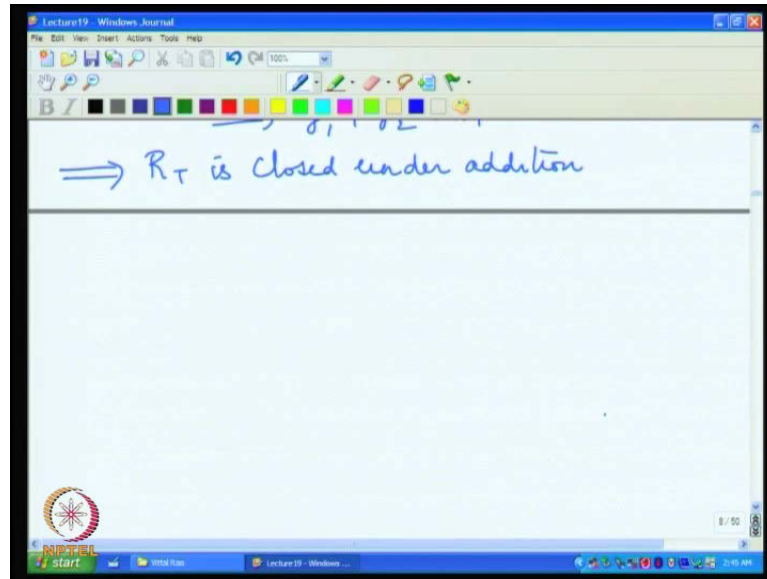

(Refer Slide Time: 18:21)

$$\begin{aligned} 1) y_1, y_2 \in \mathcal{R}_T &\Rightarrow \exists x_1 \in V \text{ s.t. } T(x_1) = y_1, \\ &\quad \exists x_2 \in V \text{ s.t. } T(x_2) = y_2 \\ &\Rightarrow \exists x_1, x_2 \in V \text{ s.t. } T(x_1) + T(x_2) = y_1 + y_2 \\ &\Rightarrow \exists x_1, x_2 \in V \text{ s.t. } T(x_1 + x_2) = y_1 + y_2 \\ &\quad \text{(since } T \text{ is l.t.)} \\ &\Rightarrow \exists z = x_1 + x_2 \in V \text{ s.t. } T(z) = y_1 + y_2 \\ &\Rightarrow y_1 + y_2 \in \mathcal{R}_T \end{aligned}$$

So, let us check whether it is closed under addition, so suppose I take y_1 and y_2 in \mathcal{R}_T we want to know, whether y_1 plus y_2 is also in \mathcal{R}_T . Now first of all, what does it mean to say that y_1 is in \mathcal{R}_T ? y_1 is in \mathcal{R}_T means it is a focal point, which means? There is a pre image x_1 in V such that, T of x_1 will be focused on y_1 , T of x_1 is y_1 . Similarly, y_2 is in \mathcal{R}_T means there exist a x_2 in V such that, T of x_2 is y_2 , which implies there exists x_1, x_2 in V such that, T of x_1 plus T of x_2 is y_1 plus y_2 . Now, since T is linear T of x_1 plus T of x_2 is T of x_1 plus x_2 . So, this means, there exist x_1, x_2 in V such that, T of x_1 plus x_2 is equal to y_1 plus y_2 since, T is linear, if T is Linear Transformation, T of x_1 plus x_2 is same as T of x_1 plus T of x_2 .

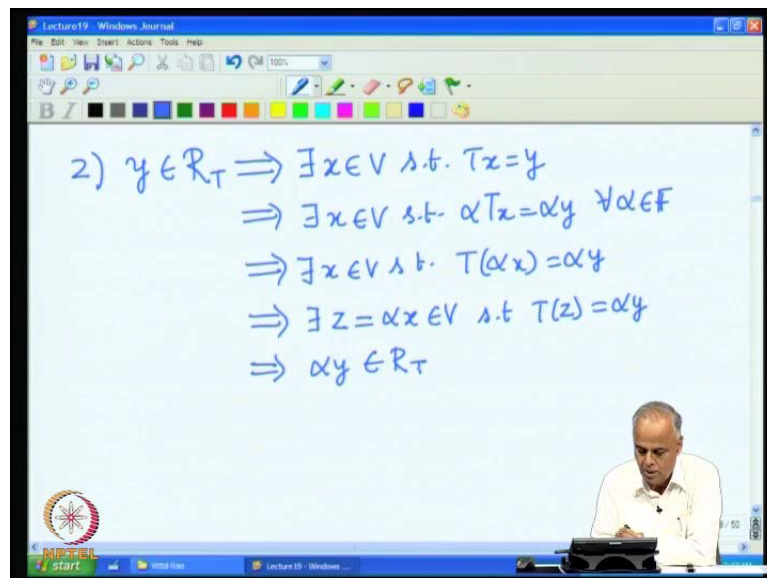

Now, if you call x_1 plus x_2 as z then, since x_1 is in V ; x_2 is in V ; x_1 plus x_2 will also be in V because V is a vector space. So, there exists z which is equal to x_1 plus x_2 in V such that, T of z is y_1 plus y_2 . This means y_1 plus y_2 is also a focal point with z being focused at y_1 and y_2 , that is the value of T at the vector z is y_1 plus y_2 , so y_1 plus y_2 is a value taken by T therefore, y_1 plus y_2 also belongs to \mathcal{R}_T .

(Refer Slide Time: 20:48)

So, y_1 and y_2 are in R_T ; y_1 plus y_2 is also in R_T which means R_T is closed under addition. Other thing that we have to check whether R_T is a subspace or not, is to see whether R_T is closed under scalar multiplication.

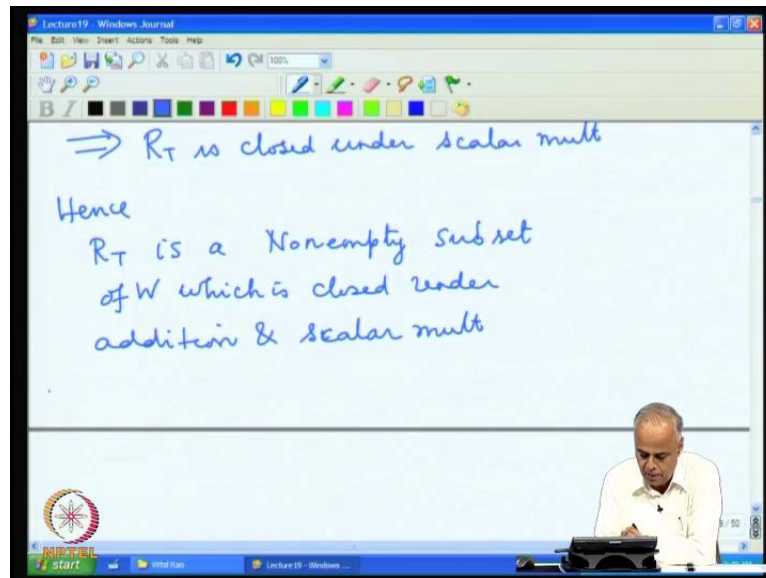

(Refer Slide Time: 21:10)

So, take a vector y in R_T we want to know whether αy will also be in R_T , if y is in R_T that means y is the value taken T at a point x , that means there exist a x in V such that $Tx = y$. If $Tx = y$; if we multiply by α , αTx will be equal to αy for every α in F . Once again, since T is linear α of Tx

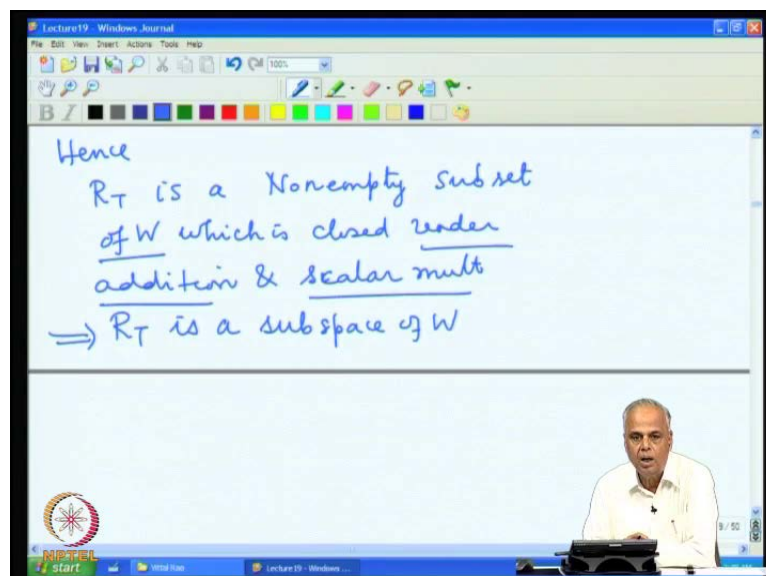

will be T of αx , so there exist a vector x in V such that, T of αx is equal to αy . Now, if we call αx is z so since, x is in V α is a scalar and V is a vector space therefore, it is closed under scalar multiplication, so z equal to αx will belong to V such that, T of z is αy . That means, αy is the value of T at the vector z or it is a focal point for the vector z and hence, αy must also belong to $R T$.

(Refer Slide Time: 22:48)

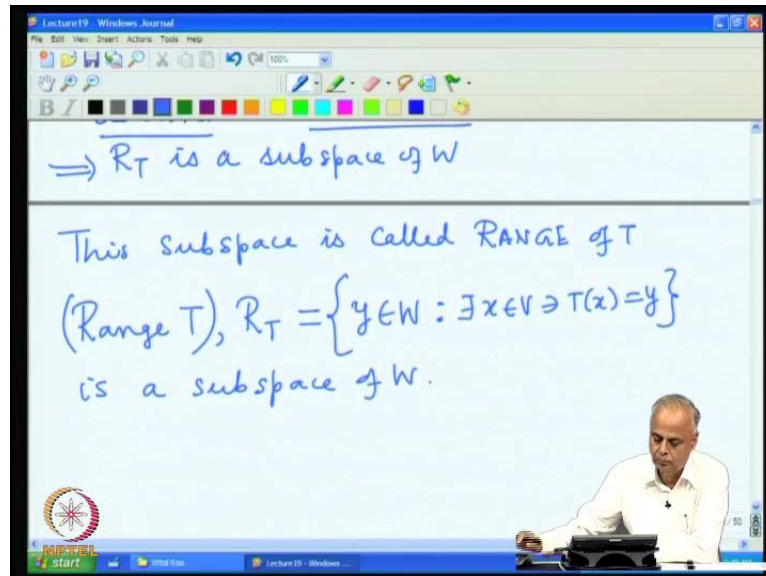

So, that says $R T$ is closed under scalar multiplication, thus we have $R T$ is a non empty subset of W which is closed under addition and scalar multiplication.

(Refer Slide Time: 23:34)

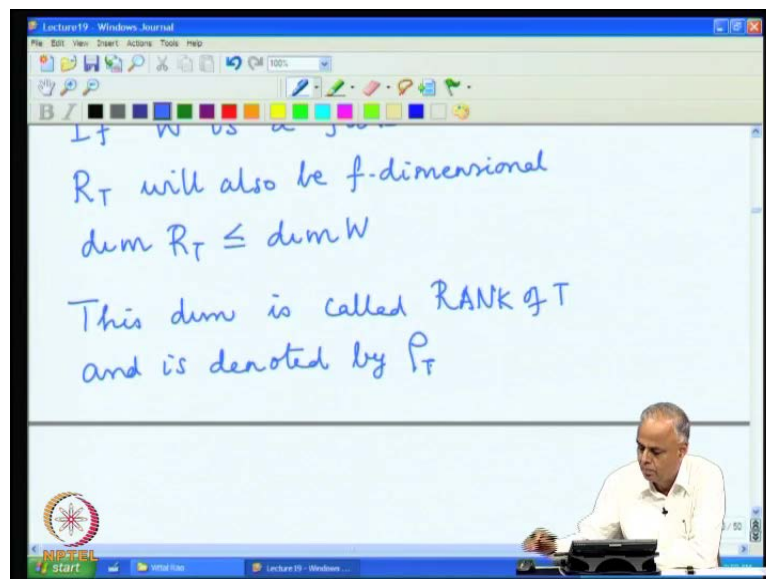

Which means R_T is a subspace of W ; R_T is a non empty subset of W which is closed under addition and scalar multiplication and hence, R_T is a subspace of W .

(Refer Slide Time: 23:58)

This subspace is called range of T , so the range of T which is denoted by R_T is equal to all those y 's in W such that, there exist a x in V whose image under T is y and this is a subspace of W .

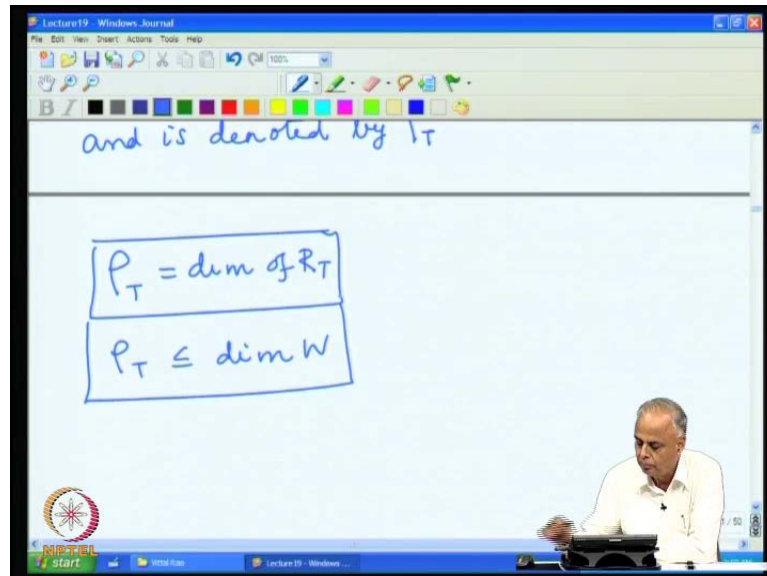

(Refer Slide Time: 24:44)

If W is a finite dimensional vector space then, R_T being a sub space of the finite dimensional subspace W will also be finite dimensional and since, is a subspace of W ;

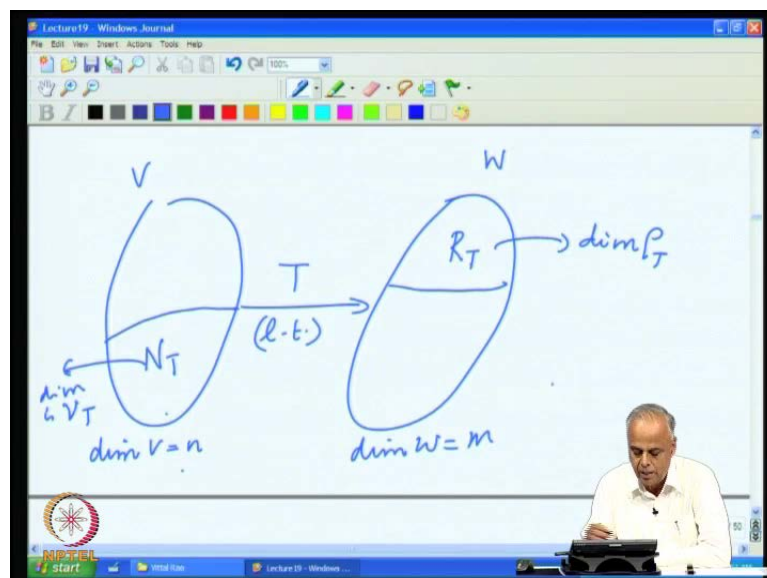

dimension of W will be less than or equal to dimension of R_T . R_T will be less than or equal to dimension of W . This dimension is called rank of T and is denoted by ρT .

(Refer Slide Time: 25:51)

So, ρT is just the dimension of range of T by dimension and ρ of T will be less than or equal to dimension of W .

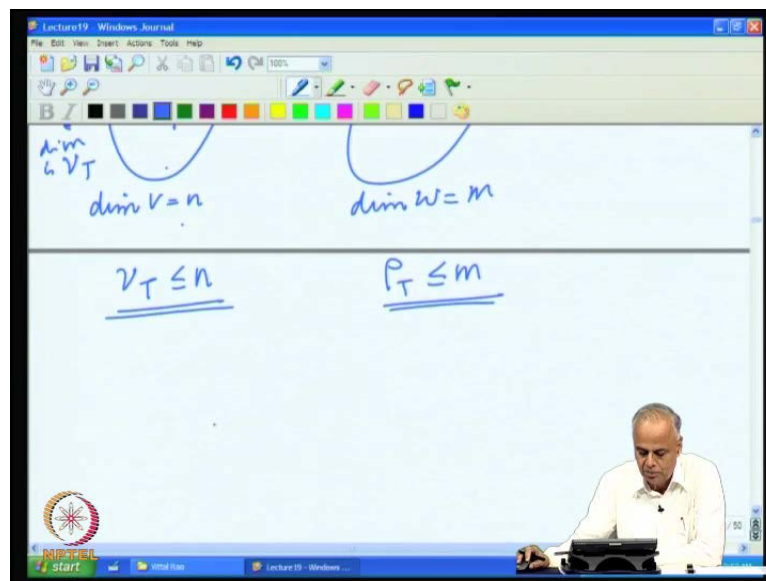

(Refer Slide Time: 26:10)

So, suppose now we have V finite dimensional, say dimension of V is n and say W finite dimensional, dimension of W equal to m and T is a Linear Transformations. So, I have two finite dimensional spaces and I have a Linear Transformation T from V to W . Now,

we have seen one subspace of V which is connected with T namely the N of T and we have seen, one subspace of W which is connected with T namely range of T and this N of T is a finite dimensional subspace of V and its dimension is called nullity and that is denoted by $\text{nu } T$. So Dimension, its dimension is $\text{nu } T$ and here, the dimension is ρ of T . At this dimension is smaller than or equal to n and this dimension is smaller than or equal to m .

(Refer Slide Time: 27:25)

So, nu of T is less than or equal to n and ρ of T is less than or equal to m , so we have two important subspaces associated with the Linear Transformation. As we go along, we will see a lot of subspaces that are connected with a Linear Transformation and these subspaces come into play in the analysis of the structure of a Linear Transformation.

(Refer Slide Time: 27:54)

EXAMPLES

(1) $V = F^n$, $W = F^m$

Let $A \in F^{m \times n}$ a fixed matrix

Define

$$T_A : F^n \longrightarrow F^m$$

as $T_A(x) = Ax$.

The screenshot also shows the NPTEL logo and a small inset of the lecturer in the bottom right corner.

Let us look at some examples, (no audio from 27:55 to 28:04) to consider V to be F^n where F is a field, W to be F^m where F is a field. So, from n component vectors or n column vector with n entries to the column vectors with m entries. Now we have a transformation, how did we define a transformation from V to W ? And the last lecture, we saw any m by n matrix will generate transformation a Linear Transformations from F^n to F^m . So, let us now consider a fixed matrix into a fixed matrix, so consider a fixed n by m matrix with entries in F then, we defined a Linear Transformation T_A from F^n to F^m as T_A takes any vector x to the vector A times x and since, A is m by n and x is n by one, the result will be m by one and therefore, it will be F^m . We have already seen in the last lecture, that this is a Linear Transformations from F^n to F^m .

(Refer Slide Time: 29:27)

We have seen that T_A is a l-t

Null space of T_A

$$x \in N_T \Leftrightarrow T_A(x) = \theta_W$$
$$\Leftrightarrow Ax = \theta_m$$

So, we have seen that T_A is a Linear Transformation from F^n to F^m , now once we have a Linear Transformation we want to what is this Null space? What is its dimension? What is the range space? And what is the dimension? So, let us look at the Null space of T_A , so in order to find Null space of T_A we want to find all those vectors which get mapped to the 0 vector. So, x in V belongs to the Null space of T if and only if somebody gets qualified to be in n_T ; if and only if it is get carried to the 0 vector; so if and only if Tx is θ_W , but then **by definition I shall put T_A** the definition of T_A is that, T_A of x is A times x . So, the image of any vector is obtained by pre multiplying it by the matrix A . So therefore, T_A of x is A of x is equal to θ_W ; what is θ_W ? This is θ_m because W is F^m . So, this is simply the homogenous system of equation $Ax = \theta_m$ and the solutions of this is what we know as the Null space of the matrix A .

(Refer Slide Time: 31:02)

$x \in N_T \iff J(x) = 0_W$
 $\iff Ax = \theta_m$
 $\iff x \in N_A$ (i.e. the set of all sol of the HS $Ax = \theta_m$)

For example $m=2, n=3$
 $V = F^3, W = F^2$

So, if and only if, x belongs to the Null space of matrix A that is the set of all solution of homogeneous system $Ax = \theta$, so the Null space of T is the same as the Null space of A . For example, if we take m equal to 2, n equal to 3 and consider F^3 to be our V and F^2 to be our W . We have to look for a matrix in m by n , F^m by F^n remember we want to, when we go from n component to m component, we need a matrix which is m by n in this case, we have m is 2 and n is 3.

(Refer Slide Time: 32:05)

$V = F^3, W = F^2$
 $A = \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix}$
 $T_A(x) = Ax$

So, we have to take a matrix which is 2 by 3, so let us say 1 0 minus 1 0 1 minus 1 then, the transformation T_A is T_A of x , now x is in F^3 will be A times x . Since x is in F^3 , A is in 2 by 3 the result will be in 2 by 1 and therefore, it will be in F^2 .

(Refer Slide Time: 32:35)

$$T_A(x) = Ax$$

$$N_{T_A} = N_A = \{x \in F^n : Ax = 0_m\}$$

$$A \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$x_1 = x_3, x_2 = x_3$$

Now, what is the Null space of T_A ? It must be equal to the Null space of A , now what is Null space of A ? The set of all x in F^m such that, Ax equal to θ_m . Now, what is Ax ? A is this matrix I do not know what x is? x must be in F^3 , so it must have three components which means 1 0 minus 1 0 1 minus 1 into x_1, x_2, x_3 is equal to θ_2 . Now, the matrix A is already in rho reduced echelon form and therefore, we can write down the solution by inspection by eliminating two of the pivotal variables; there are two pivotal variable x_1 and x_2 and the non pivotal variable is x_3 and we can eliminate x_1 and x_2 in terms of x_3 , we get x_1 equal to x_3 , x_2 equal to x_3 .

(Refer Slide Time: 33:41)

The screenshot shows a digital whiteboard with the following handwritten text:

$$N_A = \left\{ x = \begin{pmatrix} \alpha \\ \alpha \end{pmatrix} \right\}$$

We have $\therefore N_T = \uparrow$

Since $u = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ is a basis for N_T

$\dim N_T = 1$

The slide also features a video feed of a lecturer in the bottom right corner and a toolbar at the top.

And therefore, the Null space of A consists of all vectors for which x three can be chosen arbitrarily the non pivotal variable. Once, you choose the non pivotal variable, the pivotal variable have to be chosen to be equal to them and alpha can be chosen arbitrarily. And we have therefore, N_T also equal to this because N_T is equal to N_A . Now, what is the dimension of N_T ? Since, the vector 1 1 1 is a basis for N_T now, N_T is same as N_A , I should write N_{T_A} and since the basis has exactly one vector and the number of vectors in basis is called dimension, we get dimension of N_T is 1 and this dimension is called nullity.

(Refer Slide Time: 34:43)

The screenshot shows a digital whiteboard with the following handwritten text:

$\dim N_{T_A} = 1$

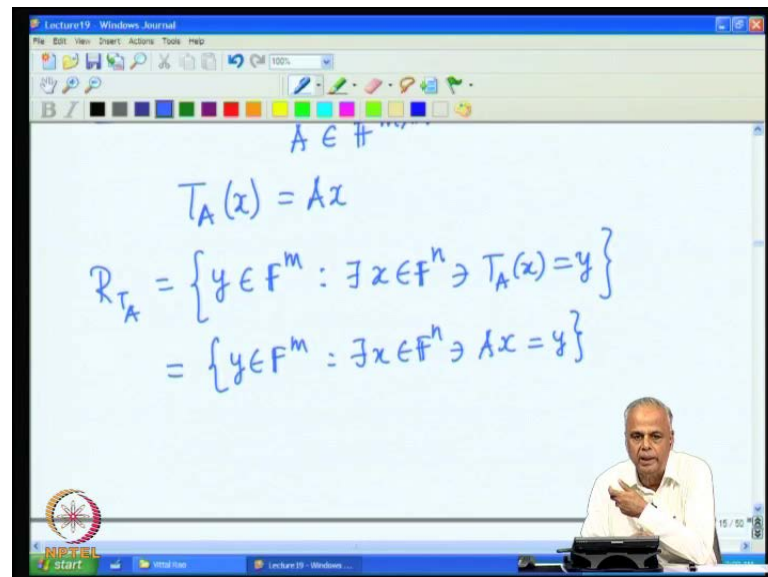

Nullity of T_A , $\nu_T = 1$

Range T_A . $V = F^n$, $W = F^m$
 $A \in F^{m \times n}$

The slide also features a video feed of a lecturer in the bottom right corner and a toolbar at the top.

Therefore, the nullity of T_A which is $\dim N(T_A) = n - \text{rank}(A)$, now let us find the range of T_A for the same transformation. First, let us look at the general matrix and then look at these examples, so once again we look at $V = F^n$ to be V , $W = F^m$ and we take a fixed matrix in $M_n(F)$.

(Refer Slide Time: 35:22)

And we look at the Linear Transformations which takes the vector x to A of x , now we want to find the range of T_A what does this range of T_A mean? To want to know the vector which are all focused by the vectors in x . So, we want to look at the range of T_A , the set of all y in F^m that is the W such that, there exist a x in V , V in this case F^n such that $T_A(x)$ is equal to y . This means we are looking at there exist a x in F^n such that, but now again T_A of x is multiplying the vector x by the matrix A , but this means we are looking at all those y for which the non-homogenous system has a solution.

(Refer Slide Time: 36:24)

The screenshot shows a whiteboard with the following handwritten text:

$$= \{y \in F^m : \exists x \in F^n \ni Ax = y\}$$

$$= \{y \in F^m : \text{The NHS } Ax=y \text{ has a sol}\}$$

$$= \text{Range of the Matrix } A$$

$$\dim R_{T_A} = \dim \text{Range } A$$

$$\parallel$$

$$\text{Rank } T_A = \text{Rank of } A$$

The slide also features the NPTEL logo and a small video inset of a lecturer in the bottom right corner.

So, this is the set of all y in F^m such that, the non homogenous system $Ax = y$ has a solution and this is what we call as a range of the matrix A and the dimension of this is called the rank of A . So, the dimension of R_{T_A} is same as the dimension of range A is called the rank of the A and it is also because the dimension of the range of T_A which is the rank of T_A .

(Refer Slide Time: 37:09)

The screenshot shows a whiteboard with the following handwritten text:

$$A = \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix} :$$

$$T_A : F^3 \longrightarrow F^2$$

$$T_A(x) = Ax$$

NHS $Ax = y$

$$\begin{pmatrix} x_1 - x_3 \\ x_2 - x_3 \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}$$

The slide also features the NPTEL logo and a small video inset of a lecturer in the bottom right corner.

Then let us go back to that example, $\begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix}$ mapping F^3 then, we have T_A mapping F^3 to F^2 where $T_A(x) = Ax$. We have already found the Null space of

this matrix; we shall now find the range of this matrix. So, now we want to know for what wise Ax equal to y has the solution, so look at the non homogenous system Ax equal to y that means Ax is x_1 minus x_3 , x_2 minus x_3 that is what Ax is, if we take a vector x_1, x_2, x_3 and pre multiplied by the matrix A , you get this and we want this to be equal to be y_1 and y_2 ; we want to know for what y_1 and y_2 will the system have a solution.

(Refer Slide Time: 38:12)

$(x_2 - x_3) = (y_2)$

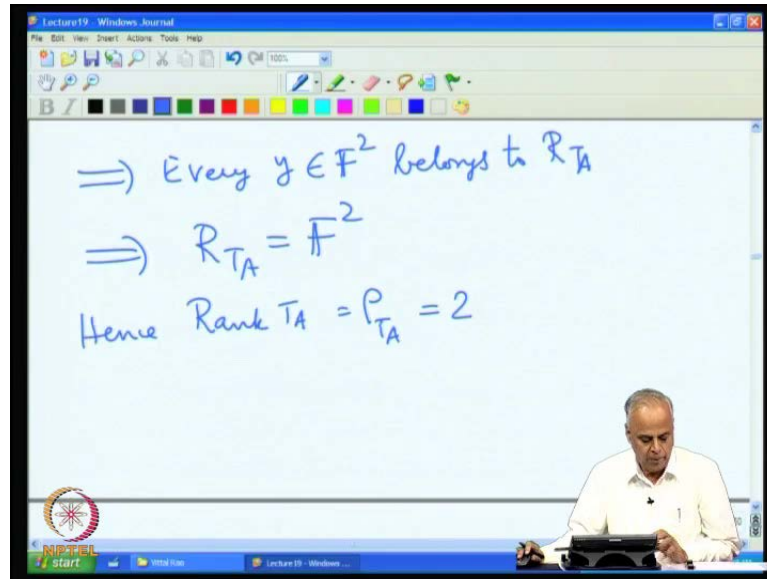

Whatever $y_1, y_2 \in F$ the system has a sol

$x_1 = y_1, x_2 = y_2, x_3 = 0$

$\therefore \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ 0 \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}$

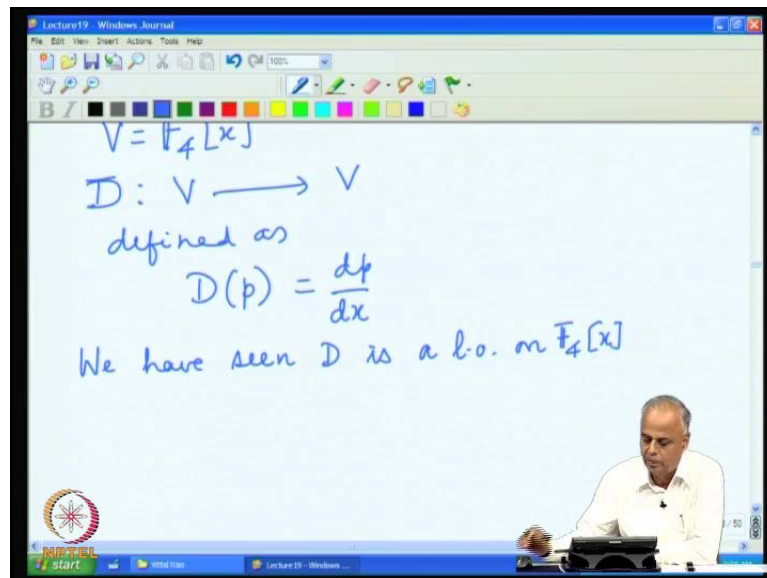

We see that whatever y_1, y_2 we chose in F , the system has a solution x_1 equal to y_1 , x_2 equal to y_2 , x_3 equal to 0 because a into $x_1, x_2, 0, y_1, y_2, 0$ is precisely equal to y_1 and y_2 and therefore, given any y_1 by 2.

(Refer Slide Time: 39:04)

Were able to construct a solution therefore, every y in F^2 belongs to R_T and therefore, R_T is all of F^2 and hence R_{TA} therefore, rank of TA which is ρ_{TA} is 2. So, thus we have very simple example of Linear Transformations from F^2 to F^3 to F^2 for which we found the Null space and the range.

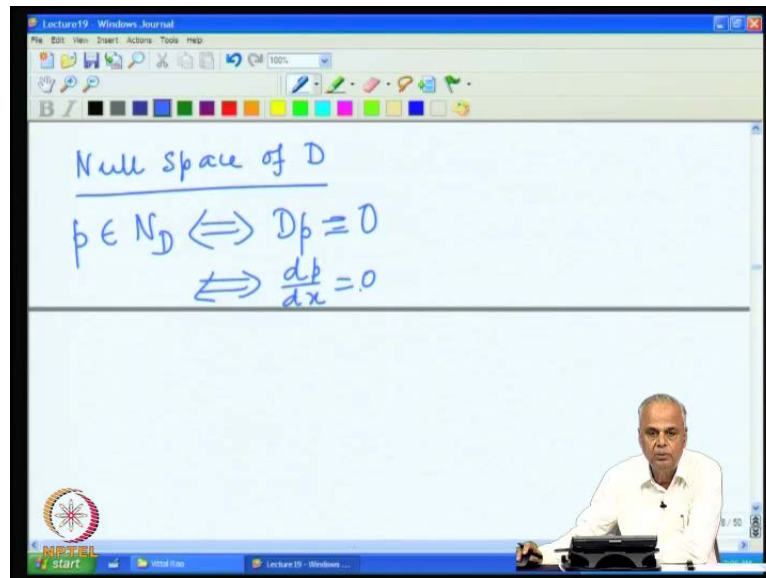

(Refer Slide Time: 39:45)

Let us look at another example; let us consider V to be the collection of all polynomials of degree less than or equal to 4 with coefficients from F . We now look at the linear operator that is a Linear Transformations from V to V , defined as D of any p is dp by dx .

The differentiation operator, we have seen in the last lecture that this is a Linear Transformation or a linear operator. We have seen D is a linear operator on $F_4(x)$, our V now is $F_4(x)$. So, let us find the Null space and the range of this operator.

(Refer Slide Time: 40:52)

So, let us find Null space of D , so we want to find those vectors in V which get mapped to the 0 vector under the transformation D . Now vectors are all polynomials because our vector space is the space of all polynomials, so we want to find all those polynomials which when differentiated gives me the 0 polynomial go to zero vector. Zero vector is the 0 polynomial so x belongs to the Null space of D ; if and only if dx is the 0 polynomial, that is if and only if let us use the notation p because we have polynomials, so dp equal to 0 . Now dp by definition, dp by dx that must be equal to 0 that is how the transformation D is defined; the transformation d is the differentiation transformation.

(Refer Slide Time: 42:07)

The image shows a digital whiteboard with the following mathematical content:

$$\Leftrightarrow \frac{dp}{dx} = 0$$
$$\Leftrightarrow p = \text{const}$$
$$\Rightarrow N_D = \{p \in F_4[x] : p = a_0, a_0 \in F\}$$

$p = 1$ is a basis for N_D

$$\therefore \dim N_D = 1.$$

So, dp by dx is equal to 0 the derivative 0 if and only if, p is a constant. So therefore, only the constant polynomials qualify to be in the Null space of D . So, thus we get the Null space of D is set of all polynomials in the vector space which are of the form p equal to some constant a naught; a naught belongs to F , they are all constant polynomials.

Now what is a basis for this space? Well the constant polynomial one is a basis for this space, so p equal to 1 is a basis for N_D because everybody else is a multiple linear combination a naught times p will get all the vectors in N_D and therefore, dimension of N_D is equal to 1 because we have a basis consisting of one vector and since, dimension of the Null space is 1; the nullity of D is 1.

(Refer Slide Time: 43:15)

$\therefore \dim N_D = 1$

$V_D = 1$

Range of D

To find all poly $p \in F_4[x]$
for which we can find.

So, thus we have found the Null space of this differentiation operator $F_4(x)$ and the nullity. Now let us look at the range of d , so to find the range of D we want to find all polynomials p in $F_4(x)$ remember now, we are looking at d as a linear operator on V . So, even the W space is now V ; so the W space is also V four x , so we are looking at all those p in $F_4 x$ for which we can find a pre image what does that mean?

(Refer Slide Time: 44:14)

a $q \in F_4[x]$ s.t.

$D(q) = p$

$\frac{dq}{dx} = p$

$q(x) = \int_0^x p(x) dx$

We can find a q which is also in that same space because they are linear operator such that, the image of q is equal to p . So, we want to find all those p 's which can be obtained

as the image of q in F_4 which means we want dq/dx must be equal to p . So, we would like to find for those p 's for which dq/dx will be equal to T then, q must be equal to $\int_0^x p(x) dx$, but then if you take any polynomial of degree four, the integral will become a polynomial of degree five and therefore, in order that q belongs to; we want q to belong to $F_4(x)$, so in order that q is a polynomial of degree less than or equal to 4, p must be a polynomial of degree less than or equal to three. So, only polynomials of degree less than or equal to three have a pre image.

(Refer Slide Time: 45:29)

In order that $q \in F_4[x]$ it is necessary that $p \in F_3[x]$

Hence $R_D = \{p \in F_4(x) = p \in F_3(x) = a_0 + a_1x + a_2x^2 + a_3x^3 \mid a_j \in F\}$

In order that q belongs to $F_4(x)$, it is necessary that p belongs to $F_3(x)$; it is a polynomial of degree less than or equal to three. Hence, the range of D is set of all polynomials in $F_4(x)$ such that p belongs to $p \in F_3(x)$. They are of form p is equal to $a_0 + a_1x + a_2x^2 + a_3x^3$ where all the a_j 's are in F . So, R_D consist of all polynomials of degree less than or equal to 3.

(Refer Slide Time: 46:25)

Hence $R_D = \{ p \in F_4[x] = \{ p \in F_3[x] \}$
 $p = a_0 + a_1x + a_2x^2 + a_3x^3$
 $a_j \in F$

$\dim R_D = 4$
 $\text{Rank } D, \rho_D = 4.$

Now what is the dimension R_D , we have seen that one x , x square x cube form a basis and therefore, the dimension is 4 and therefore, rank D which is ρ_D is equal to 4.

(Refer Slide Time: 46:48)

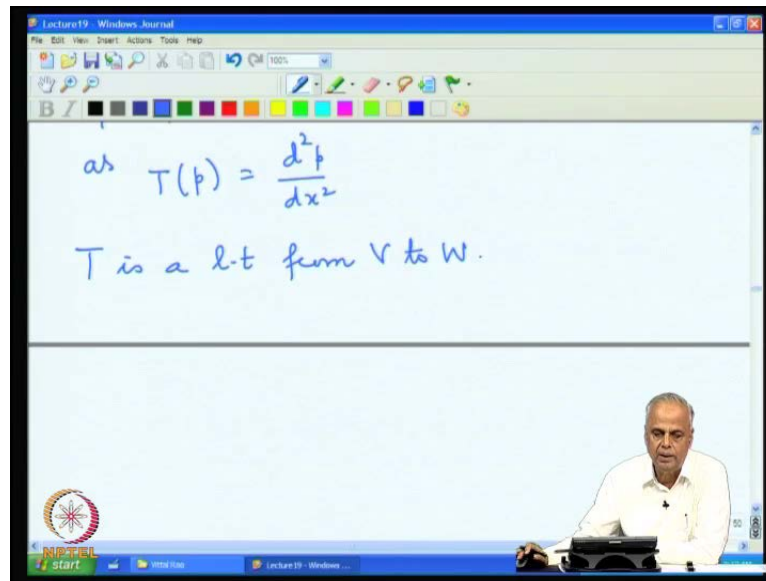

EXAMPLE 5

$V = F_4[x], W = F_3[x]$

$T: V \longrightarrow W$ defined as
as $T(p) = \frac{d^2p}{dx^2}.$

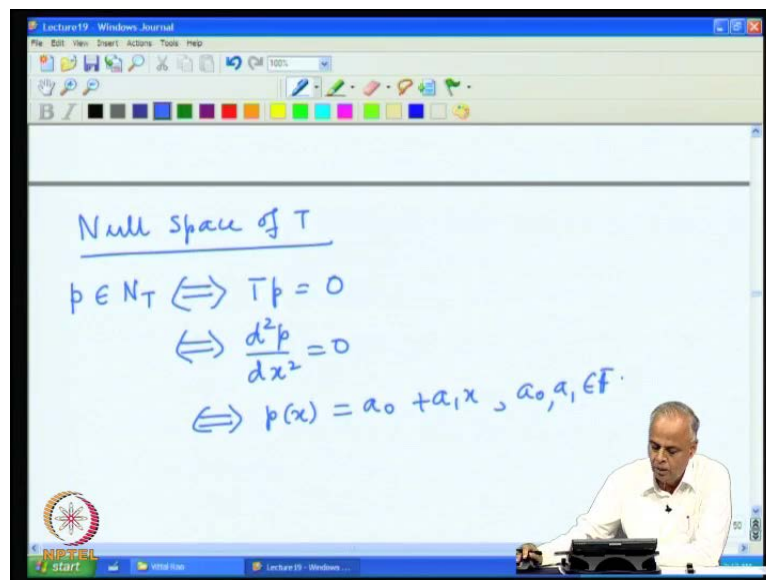

We will see one more example, similar to the one above. Take V equal to $F_4(x)$ and then say W equal to $F_3(x)$ and then consider the transformation D , let us call it as T because D we use for differentiation, T mapping V to W defined as T of p is the second derivative of p . Now again in last lecture, we verified that this is a Linear Transformations from V to W .

(Refer Slide Time: 47:36)

So, T is a Linear Transformation from V to W , the once we have Linear Transformation we want to find is Null space and the range.

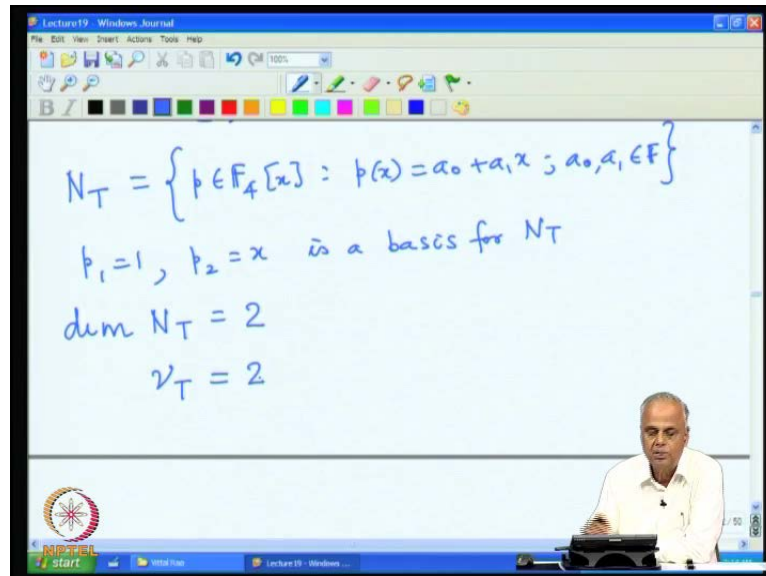

(Refer Slide Time: 47:49)

Now let us find the Null space of T ; now the Null space of T is all those vectors which get focused to the 0 vector. Vectors here are all polynomials so p belongs to the Null space of T , if and only if it gets focused to the 0 polynomial or its value under T is the 0 polynomial. If and only if T is defined as d^2 , so it is $d^2 p$ by dx^2 is 0

this means, $p(x)$ is a linear polynomial $a_0 + a_1x$ where a_0 and a_1 belong to F . Therefore, only linear polynomials qualify to be in the Null space of T .

(Refer Slide Time: 48:46)

The screenshot shows a whiteboard with the following text written in blue ink:

$$N_T = \{p \in F_4[x] : p(x) = a_0 + a_1x ; a_0, a_1 \in F\}$$

$p_1 = 1, p_2 = x$ is a basis for N_T

$$\dim N_T = 2$$
$$\nu_T = 2$$

In the bottom right corner, a lecturer is visible, sitting at a desk. The window title is "Lecture19 - Windows Journal".

So therefore, we get Null space of T consist of all those polynomial in $F_4(x)$ which are of the form $p(x) = a_0 + a_1x$; $a_0, a_1 \in F$. Now clearly $p_1 = 1$, $p_2 = x$ is a basis for N_T because as we seen here, every other polynomial is a linear combination of polynomial one and the polynomial x and therefore, they form a spanning set and obviously, linearly independent and therefore, they form a basis. So, the dimension of N_T since the basis consists of two vectors now, the dimension of N_T is 2, so the nullity of T is dimension is 2 which implies nullity of T ; which is defined to be the dimension of N_T is 2.

(Refer Slide Time: 49:53)

Range of T

To find all poly $p \in \mathbb{F}_3[x]$ for which $\exists q \in \mathbb{F}_4[x]$ s.t.

$$T(q) = p$$
$$\frac{d^2q}{dx^2} = p$$

Since $q \in \mathbb{F}_4[x]$ we have $\frac{d^2q}{dx^2} \in \mathbb{F}_2[x]$

Let us now look at the range; the range of T we want to find all polynomials p in now, the W space is $\mathbb{F}_3(x)$; our W space in this case is $\mathbb{F}_3(x)$. So, we want to find all those polynomials in $\mathbb{F}_3(x)$ that means polynomials of degree less than or equal to 3. We want to find all those polynomials for which there is a pre image; for which there exist a q pre image must be from V , V is $\mathbb{F}_4(x)$ in our case therefore, q belonging to $\mathbb{F}_4(x)$ such that $T(q)$ equal to p . If you want $T(q)$ to be equal to p , since T is defined as d^2q by dx^2 , we want to find those p 's in $\mathbb{F}_3(x)$ for which we can find q in $\mathbb{F}_4(x)$ such that d^2q is equal to dx^2 .

Now, if q has to be in $\mathbb{F}_4(x)$ is a polynomial of degree less than or equal to 4, and so when we differentiate it twice, it will lose two degrees. Every derivative reduces the power by one in the polynomial; degree by one in the polynomial. So, if we take any polynomial in $\mathbb{F}_4(x)$ and differentiate it twice on the left hand side, we will get only polynomials of degree two or less and therefore, p has to be a polynomial of degree two or less. Since, q belongs to $\mathbb{F}_4(x)$ we have d^2q belongs to $\mathbb{F}_2(x)$, it has to be polynomial of degree less than or equal to 2.

(Refer Slide Time: 52:05)

The screenshot shows a digital whiteboard with the following handwritten text:

$$\frac{d^2 q}{dx^2} = p$$

Since $q \in \mathbb{F}_4[x]$ we have $\frac{d^2 q}{dx^2} \in \mathbb{F}_2[x]$
& hence p has to be in $\mathbb{F}_2[x]$
For every $p \in \mathbb{F}_2[x]$ if we define
$$q = \int_0^x \left(\int_0^x p(x) dx \right) dx$$

The video shows a lecturer in a white shirt sitting at a desk in the bottom right corner of the whiteboard interface.

And hence, p has to be in $\mathbb{F}_2[x]$, so we know that if at all there is going to be a solution for this you mean better start with p which is in $\mathbb{F}_2[x]$, but then for every p in $\mathbb{F}_2[x]$. If we define q to be $\int_0^x \int_0^x p(x) dx dx$ then, since p is a polynomial of degree less than or equal to degree two, when I integrate it will be polynomial of degree less than or equal to three and if I integrate further, I will get a polynomial of degree less than or equal to four.

(Refer Slide Time: 53:01)

The screenshot shows a digital whiteboard with the following handwritten text:

then $q \in \mathbb{F}_4[x]$ and
$$Dq = \frac{d^2 q}{dx^2} = p$$

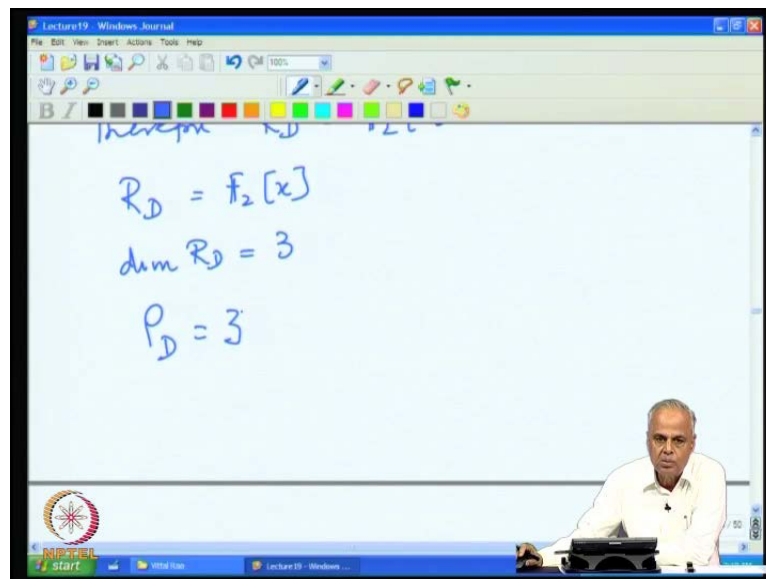

& hence $p \in \mathbb{R}_D$
Therefore $\mathbb{R}_D = \mathbb{F}_2[x]$
$$\mathbb{R}_D = \mathbb{F}_2[x]$$

$$\dim \mathbb{R}_D = 3$$

The video shows a lecturer in a white shirt sitting at a desk in the bottom right corner of the whiteboard interface.

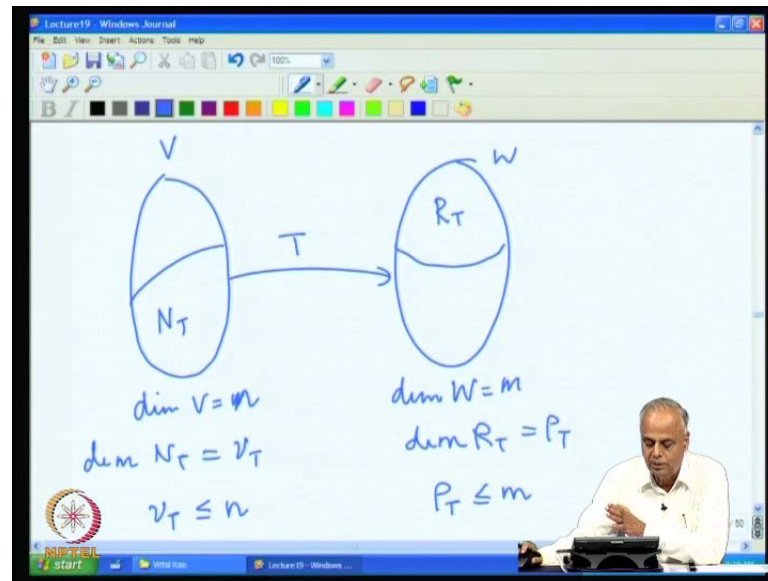

So, q will be in $F_4(x)$ and if we differentiate that is D of q will be precisely p and hence, p will belong to range of D . Therefore, range of D is precisely $F_2(x)$, what we have shown is take any vector in $F_2(x)$ it is in the range and previously we showed, that if it has to be in range, it has to be in $F_2(x)$ and therefore, $F_2(x)$ is precisely the range of D . So, the range of D is $F_2(x)$ and therefore, the dimension of R_D is dimension of F_2 , which is three because one x^2 square form basis for all polynomials, whose degree is less than or equal to 3 or less than or equal to 2.

(Refer Slide Time: 54:09)

And therefore, the rank of D is 3. So, these are some simple example of looking at the range and the Null space.

(Refer Slide Time: 54:21)

Now what we have so far is; here is the vector space V ; here is the vector space W and the dimension of V is equal to n , say dimension of W equal to m and there is a Linear Transformation T and then, a part of this is what is known as the Null space of T and the part of this is what is known as the range of T and the dimension of n of T is what is known as ν of T and the dimension of ρ of R of T is what is known as ρ of T and since, Null space of T is a part of V and we have ν of T is less than or equal to n similarly, we have ρ of T is less than or equal to m .

Now, we have one subspace on V which comes from T ; we have one subspace on W which comes from T . Is there a connection between these two? And there is a connection between the dimensions and that is what is known as the rank nullity theorem. We shall first take this and we have look a proof of this in the next lecture. Now, what is the statement? Let us look at the three examples we had, in each of this examples if you see the first example, let us even take the last example. We have the n is 5 in this case because F 4 m is 3, so n is 5, nullity was 2 and rank was 3.

(Refer Slide Time: 56:15)

The screenshot shows a whiteboard with the following handwritten text:

& hence $P_D = 3$

Therefore $R_D = F_2[x]$

$R_D = F_2[x]$

$\dim R_D = 3$

$P_D = 3$

$\text{Rank } D + \text{Nullity } D = 2 + 3 = 5 = \dim V$

And the rank plus nullity came out to be in this example, we got rank D plus nullity D was equal to 2 plus 3 which is 5; which is equal to the dimension of V . And now this is not an accident, and the fact this is not an accident and this is always true for Linear Transformations is known as the rank nullity theorem which we will look at in the next class.
