Inner Product and Orthogonality- Part 5

(Refer Slide Time: 00:19)

Orthonormal sets

$$S \subseteq \mathbb{R}^k \text{ s.t. } (\varphi, \psi) = \begin{cases} 0 & \text{if } \varphi \neq \psi \\ 1 & \text{if } \varphi = \psi \end{cases}$$

$\varphi, \psi \in S$

---

Orthonormal Basis

A basis for  $\mathbb{R}^k$  which is an o.n. set is called an o.n.b.

We have been looking at orthonormal sets, and the notion of the orthogonal complement of a given subspace. So, let us recollect some of the basic ideas, suppose we have a set  $S$  in  $\mathbb{R}^k$ , such that  $\varphi \psi$  is equal to 0 if  $\varphi$  not equal to  $\psi$  and 1 if  $\varphi$  equal to  $\psi$  where  $\varphi$  and  $\psi$  are in  $S$ , then we say  $S$  is an orthonormal set. And then we had the notion of an orthonormal basis, so your base is which is an orthonormal set is called an orthonormal basis, so your base is for  $\mathbb{R}^k$  which is an orthonormal set is called an orthonormal basis. This is very important notion that we have introduced and using this orthonormal basis, we showed that any vector can be expanded in terms of the orthonormal basis.

(Refer Slide Time: 01:36)

Orthonormal Basis

A basis for  $\mathbb{R}^k$  which is an o.n. set is called an o.n.b.  $\mathcal{B} = \{\varphi_j\}_{j=1}^k$  o.n.b.

$$x \in \mathbb{R}^k \Rightarrow x = \sum_{j=1}^k (x, \varphi_j) \varphi_j \quad (x, \varphi_j) = \varphi_j^T x$$
$$\Rightarrow \|x\|^2 = \sum_{j=1}^k (x, \varphi_j)^2$$

The slide also features a video feed of a lecturer at the bottom right and an NPTEL logo at the bottom left.

So, if we have  $x$  in  $\mathbb{R}^k$  the expansion becomes easy, the vector  $x$  can be written as  $\sum_{j=1}^k x_j \varphi_j$ , where  $\varphi_j$  is the orthonormal basis  $j$  equal to 1 to  $k$ .

Suppose, we had an orthonormal basis, then any vector in  $\mathbb{R}^k$  can be expanded in terms of these  $\varphi_j$  and the coefficients in the expansion are nothing but the inner product of  $x$  with a vector  $\varphi_j$ , recall  $x \varphi_j$  is only another notation for  $\varphi_j^T x$ . Now, once we have this from this we also have that the length of  $x$  square is given by the sum of these  $x \varphi_j$  square.

(Refer Slide Time: 02:35)

$$\Rightarrow \|x\|^2 = \sum_{j=1}^k (x, \varphi_j)^2$$

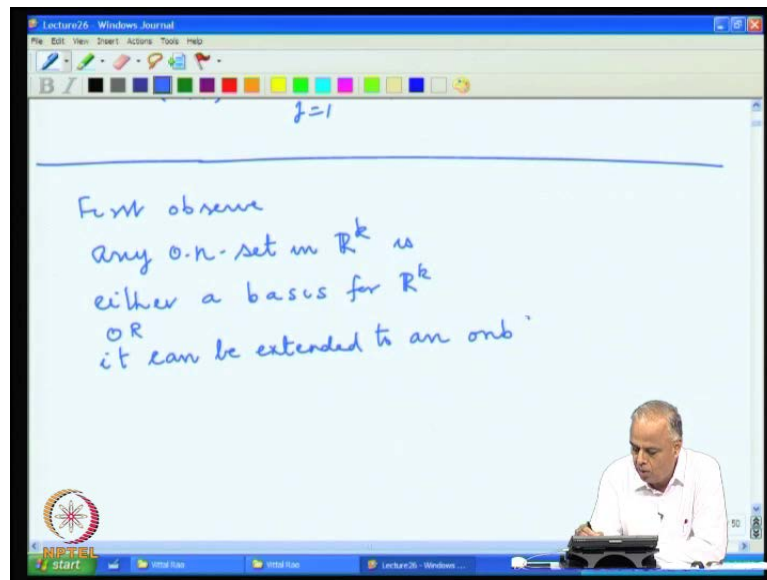

Also if  $x, y \in \mathbb{R}^k$  then

$$(x, y) = \sum_{j=1}^k (x, \varphi_j)(y, \varphi_j)$$

The slide also features a video feed of a lecturer at the bottom right and an NPTEL logo at the bottom left.

Also, we have if  $x$  and  $y$  are in  $\mathbb{R}^k$  then the inner product of  $x$  and  $y$  or the dot product of  $x$  and  $y$  just in terms of these coefficients is just  $x_j \phi_j + y_j \phi_j$ . So, the expansion in terms of orthonormal sets is akin to the expansion with respect to the  $i, j, k$  vectors which you might have learnt at an earlier class.

(Refer Slide Time: 03:27)

Now, having got this orthonormal set then we introduced the notion of a orthogonal complement for a subspace. Now, we observed first we if you have any orthonormal set in  $\mathbb{R}^k$  is either a basis for  $\mathbb{R}^k$  or it can be extended to an orthonormal basis for  $\mathbb{R}^k$ . We use this notion in analyzing what is known as the orthogonal complement of a subspace.

(Refer Slide Time: 04:14)

The image shows a screenshot of a lecture slide from a video recording. The slide is titled "Lecture26" and "Windows Journal". It contains handwritten text in blue ink. The text reads: "W a subspace of  $\mathbb{R}^k$ ", "Orthogonal complement of W is defined as", and the equation  $W^\perp = \{x \in \mathbb{R}^k : (x, w) = 0 \forall w \in W\}$ . Below this, it says "We observed the following facts:" followed by two numbered points: "1  $W^\perp$  is a subspace of  $\mathbb{R}^k$ " and "2 If  $B_W$  is a basis for W and  $B_{W^\perp}$  is a basis for  $W^\perp$ ". In the bottom right corner of the slide, there is a small inset video of a man in a white shirt sitting at a desk. The NPTEL logo is visible in the bottom left corner of the slide.

So, then we introduced the notion which we looked last time namely the  $W$  is a subspace of  $\mathbb{R}^k$  then, the orthogonal complement of  $W$  is defined as  $W^\perp$  that is the notation for the orthogonal complement. It consists of all those vectors in  $\mathbb{R}^k$  which are perpendicular which are orthogonal that is the dot product is 0 for every vector in  $W$  that is these are vectors which are orthogonal to everyone of the vectors in  $W$ .

We observed in the last lecture the following facts what are they? the first thing that we observed was the  $W^\perp$  is a subspace of  $\mathbb{R}^k$ . This is the first simple observation the  $W^\perp$  is forced to be a subspace of  $\mathbb{R}^k$ , the second thing we observed was that if  $B_W$  is a basis for  $W$  and  $B_{W^\perp}$  is a basis for  $W^\perp$ . So, you have a basis for  $W$  and you have basis for  $W^\perp$ .

(Refer Slide Time: 05:56)

1  $W^\perp$  is a subspace of  $\mathbb{R}^k$

2 If  $B_W$  is a basis for  $W$  and  $B_{W^\perp}$  is a basis for  $W^\perp$

then  $B = \underline{B_W \cup B_{W^\perp}}$  is a basis for  $\mathbb{R}^k$

3  $\dim W + \dim W^\perp = \dim \mathbb{R}^k = k$

4.  $O_W$  an o.n.-b. for  $W$  and  $O_{W^\perp}$  an o.n.-b. for  $W^\perp$  then

Then if you put them together let us call that  $B$  as  $B_W \cup B_{W^\perp}$  is a basis for the whole space so, we can get a basis for the whole space by getting a basis for  $W$  and a basis for orthogonal complement, a consequence of two is the fact that the dimension of  $W$  plus dimension of  $W^\perp$  is equal to the dimension of  $\mathbb{R}^k$  which is  $k$ . The dimension of a subspace plus the dimension of its orthogonal complement is always equal to the dimension of the whole space because the number of vectors in the basis  $W$  is equal to the number of vectors in the basis  $W^\perp$ . So, the dimension of  $W$  plus dimension of  $W^\perp$  is equal to the dimension of  $\mathbb{R}^k$ .

Another special version of two is the fact that if you take an orthonormal basis for  $W$  so, let us call it as  $O_W$  an orthonormal basis for  $W$  and  $O_{W^\perp}$  an orthonormal basis for  $W^\perp$ , then putting them together we get an orthonormal basis for the whole space.

(Refer Slide Time: 07:26)

4.  $\mathcal{O}_W$  an o.n.-b. for  $W$  and  
 $\mathcal{O}_{W^\perp}$  " "  $W^\perp$  then  
 $\mathcal{O} = \mathcal{O}_W \cup \mathcal{O}_{W^\perp}$  is an o.n.-b. for  $\mathbb{R}^k$

5 Any vector  $x \in \mathbb{R}^k$  can be decomposed  
as a sum  
 $x = x_W + x_{W^\perp}$  where  
 $x_W \in W$  and  $x_{W^\perp} \in W^\perp$  in  
a unique manner

Then  $\mathcal{O}$  equal to  $\mathcal{O}_W \cup \mathcal{O}_{W^\perp}$  is an orthonormal basis for  $\mathbb{R}^k$ . Therefore, you can put together basis for  $W$  and  $W^\perp$  to get a basis for the whole space you can put together an orthonormal basis for  $W$  and an orthonormal basis for  $W^\perp$  to get an orthonormal basis for the whole space. We further observed using these facts that any vector  $x$  in  $\mathbb{R}^k$  can be decomposed as the sum of two vectors  $x_W$  plus  $x_{W^\perp}$  where  $x_W$  belongs to  $W$  and  $x_{W^\perp}$  belongs to  $W^\perp$  and this decomposition is unique in a unique way.

So, what really matters here is that the basis can be split a part in to two parts that is the basis for the whole space can be split into the basis for  $W$  and the basis for  $W^\perp$  the orthogonal basis for the whole space can be split into an orthogonal basis for  $W$  and an orthogonal basis for  $W^\perp$ , this allows us to split a vector into two parts one part coming from  $W$  and the other part coming from  $W^\perp$ .

(Refer Slide Time: 09:12)

a unique manner

6. Pythagoras Theorem:

$$\|x\|^2 = \|x_W\|^2 + \|x_{W^\perp}\|^2$$

7  $x_W$  = Orthogonal projection of  $x$  onto  $W$

$x_{W^\perp}$  : orthogonal projection of  $x$  onto  $W^\perp$

The slide is a screenshot of a Windows Journal window titled "Lecture26 - Windows Journal". It contains handwritten text and a mathematical equation. The text describes the Pythagorean Theorem for orthogonal projections. The equation is  $\|x\|^2 = \|x_W\|^2 + \|x_{W^\perp}\|^2$ . Below the equation, it states that  $x_W$  is the orthogonal projection of  $x$  onto  $W$ , and  $x_{W^\perp}$  is the orthogonal projection of  $x$  onto  $W^\perp$ . The slide also features the NPTEL logo and a small video inset of a lecturer in the bottom right corner.

And we had the consequential Pythagoras Theorem which was a at that when we do such a splitting the length of  $x$  squared will be the length of  $x_W$  squared plus the length of  $x_{W^\perp}$  squared. The  $x_W$  is what we called as the orthogonal projections of  $x$  onto  $W$  and  $x_{W^\perp}$  is called the orthogonal projection of  $x$  onto  $W^\perp$ . So, these are some of the important facts about orthonormal sets orthonormal basis the orthogonal complement and their basis and the splitting that we have studied so far, let us look at a simple example to illustrate all these facts.

(Refer Slide Time: 10:21)

Example:  $\mathbb{R}^3$

$$W = \left\{ x = \begin{pmatrix} \alpha \\ \alpha \\ \alpha \end{pmatrix} : \alpha \in \mathbb{R} \right\}$$

$W$  is a subspace

$\alpha_W = u_1 = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$  is a basis for  $W$

$\dim W = 1$

What is  $W^\perp$ ?

$$W^\perp = \left\{ x = \begin{pmatrix} \alpha \\ \beta \\ -\alpha - \beta \end{pmatrix} : \alpha, \beta \in \mathbb{R} \right\}$$

The slide is a screenshot of a Windows Journal window titled "Lecture26 - Windows Journal". It contains handwritten text and mathematical expressions. The text starts with "Example:  $\mathbb{R}^3$ " and defines a subspace  $W = \{ x = \begin{pmatrix} \alpha \\ \alpha \\ \alpha \end{pmatrix} : \alpha \in \mathbb{R} \}$ . It then states that  $W$  is a subspace and that  $\alpha_W = u_1 = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$  is a basis for  $W$ . It also notes that  $\dim W = 1$ . The text then asks "What is  $W^\perp$ ?" and provides the answer:  $W^\perp = \{ x = \begin{pmatrix} \alpha \\ \beta \\ -\alpha - \beta \end{pmatrix} : \alpha, \beta \in \mathbb{R} \}$ . The slide also features the NPTEL logo and a small video inset of a lecturer in the bottom right corner.

Let us consider  $\mathbb{R}^3$  and consider the subspace  $W$  which consists of all vectors of the form  $a \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$  where  $a$  belongs to  $\mathbb{R}$  that is, it is the subspace consisting of all those vectors which have all components equal to each other, the first component is  $a$ , the second component is  $a$  and the third component is  $a$  so to say the collection of all vectors which have all components equal to each other.

Now,  $W$  is a subspace we have seen this before and if you take  $B_W$  to be the simple vector  $\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$  then, this is a basis for  $W$  you see easy to verify that this is a basis for  $W$  because  $\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$  as all components equal and therefore,  $u_1$  belongs to  $W$  and any vector in  $W$  is just  $a$  times  $u_1$  and therefore, a linear combination of  $u_1$  and  $u_1$  is linearly independent and therefore,  $B_W$  is a linearly independent set in  $W$  which spans  $W$  and hence, it is a basis for  $W$ . Now, what do we get immediately out of this the dimension of  $W$  is equal to 1 so this is a basis for  $W$  and the dimension of  $W$  is equal to 1 because there is only 1 vector in the basis.

What is  $W^\perp$ ? we have already seen this in the previous lecture and the  $W^\perp$  turns out to be this set of all vectors of the form  $\alpha \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \beta \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} + \gamma \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$  where  $\alpha$  and  $\beta$  are real numbers. That is the set of all those vectors whose sum of the components must be 0 the sum of the components must be 0 because it must be orthogonal to the basis vector of  $W$  which says since, all the components of the basis vectors are 1 because or dot product will be the sum of the components so the sum of the components must be 0 and hence,  $W^\perp$  is of this form if it of this form.

(Refer Slide Time: 13:02)

$B_{W^\perp} : w_1 = \begin{pmatrix} 0 \\ 1 \\ -1 \end{pmatrix}, w_2 = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$  is a basis for  $W^\perp$

We see that  $\dim W^\perp = 2$

$\dim W + \dim W^\perp = 1 + 2 = \dim \mathbb{R}^3$

We can easily see that  $B_{W^\perp}$  consisting of these following vectors  $w_1$  equal to  $\begin{pmatrix} 0 \\ 1 \\ -1 \end{pmatrix}$   $w_2$  is equal to  $\begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$ . These two vectors are obtained as follows by putting  $\alpha$  equal to 1 and  $\beta$  equal to 0 we get  $w_1$  by putting  $\alpha$  equal to 0 and  $\beta$  equal to 1 we get  $w_2$ . Therefore,  $w_1$  and  $w_2$  are vectors in  $W^\perp$  they are obviously linearly independent and any vector in  $W^\perp$  is  $\alpha w_1 + \beta w_2$  and Hence, the span  $W^\perp$  so these two vectors are in  $W^\perp$  they are linearly independent they span  $W^\perp$  and hence they form a basis for  $W^\perp$ .

Now, we see that since the basis consists of two vectors dimension of  $W^\perp$  is 2 and therefore, we immediately see that dimension of  $W$  plus dimension of  $W^\perp$  is equal to 1 plus 2 which is the dimension of the whole space. This is one of the properties which we looked at last time this illustrates the fact that the dimension of a subspace plus the dimension of the orthogonal complement must always be equal to the dimension of the whole space.

(Refer Slide Time: 14:41)

If we set

$$B_0 = B_W \cup B_{W^\perp}$$
$$= u_1 = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, w_1 = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}, w_2 = \begin{pmatrix} 0 \\ 1 \\ -1 \end{pmatrix}$$

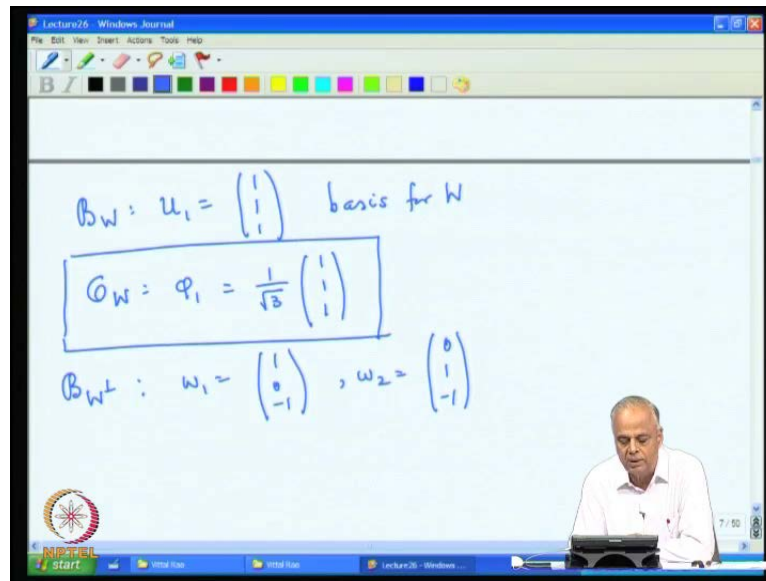

These are l.i. (Easy to check)  
They form a basis for  $\mathbb{R}^3$  since any three l.i. vectors in  $\mathbb{R}^3$  form a basis for  $\mathbb{R}^3$

We also see that if we set  $B$  equal to  $B_W$  Union  $B_{W^\perp}$  we get the vectors  $u_1$  equal to  $(1, 1, 1)$ ,  $w_1$  equal to  $(1, 0, -1)$  and  $w_2$  equal to  $(0, 1, -1)$ . Now, it is very easy to see that these three vectors are linearly independent so, these are linearly independent. I will just put easy to check, these are the linearly independent vectors but we are in the space  $\mathbb{R}^3$ . since the dimension is three any three linearly independent vectors will form a basis and therefore, they form a basis for  $\mathbb{R}^3$  since, any three linearly independent vectors in  $\mathbb{R}^3$  form a basis for  $\mathbb{R}^3$ .

This illustrates the fact that if you put together a basis for  $W$  and a basis for  $W^\perp$  you will get a basis for  $W \cup W^\perp$  the whole space so, if you put a basis for  $W$  and a basis for  $W^\perp$  together you will always get a basis for the whole space which is what gives the fact that the dimension of  $W$  plus dimension of  $W^\perp$  is the dimension of the whole space.

Now, let us look at the orthonormal versions of this basis.

(Refer Slide Time: 16:34)

Now, let us look at  $B_W$  which is a basis for  $W$  now, since there is only 1 vector to get an orthonormal basis all we have to do is normalize it to have length 1 and therefore, the orthonormal basis for  $W$  will be just dividing by the length the  $u_1$  divided by its length gives us  $o_w$  so this is an orthonormal basis for  $W$ .

Now, let us look at  $B_{W^\perp}$  may recall we have got the  $W^\perp$  basis as  $w_1$  and  $w_2$  this is the basis for the  $W^\perp$  let us take these two basis  $w_1$  which is 1 0 minus 1 and  $w_2$  which is 0 1 minus 1. In order to extract an orthonormal basis out of it we have to apply the Gram Schmidt process.

(Refer Slide Time: 17:46)

$B_{W^\perp} : w_1 = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}, w_2 = \begin{pmatrix} 0 \\ 1 \\ -1 \end{pmatrix}$

Apply G-S orthonormalization to  $B_{W^\perp}$

$v_1 = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} \quad \|v_1\|^2 = 2 \quad \psi_1 = \frac{v_1}{\|v_1\|} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$

$v_2 = \begin{pmatrix} 0 \\ 1 \\ -1 \end{pmatrix} - \frac{(v_2, v_1)}{\|v_1\|^2} v_1$

So, apply the Gram Schmidt process orthonormalization to  $B_{W^\perp}$ . We apply the Gram Schmidt orthonormalization to  $B_{W^\perp}$  the result will be we will get an orthonormal basis  $o_{W^\perp}$  for  $W^\perp$ . How does the orthonormalization process go first, we start with the first vector  $w_1$  and call it as  $v_1$  find its length squared which is 2 and then consider the vector  $\psi_1$  which is obtained by dividing  $v_1$  by its norm which in this case is  $1/\sqrt{2}$   $1/\sqrt{2}$   $0$   $-1/\sqrt{2}$ .

So, that is our first vector in the orthonormal basis in order to get the second vector we start with the second vector which is  $0$   $1$   $-1$  the second vector in the basis  $B_{W^\perp}$  is  $w_2$ . We start with that vector and then, we subtract the dot product of  $v_2$  with  $v_1$  divide by its length and multiply by  $v_1$  this is what the first step of orthogonalization in the Gram Schmidt process. What does this give us  $0$   $1$   $-1$  dot product of  $v_2$  and  $v_1$  is  $0$  times  $1$  plus  $1$  time  $0$  plus  $-1$  into  $-1$  which is  $+1$  so,  $v_2 \cdot v_1$  is  $1$  norm  $v_2 \cdot v_1$  squared is  $2$  into  $v_1$  which is  $1$   $0$   $-1$  which gives me  $-1/2$  and  $-1/2$ .

(Refer Slide Time: 19:36)

$$\begin{aligned}
 &= \begin{pmatrix} 0 \\ 1 \\ -1 \end{pmatrix} - \frac{1}{2} \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} \\
 &= \begin{pmatrix} -1/2 \\ -1/2 \\ -1 \end{pmatrix} \quad \|v_2\|^2 = \frac{1}{2^2} (1+2+1) \\
 \frac{v_2}{\|v_2\|} = \psi_2 &= \frac{1}{\sqrt{6}} \begin{pmatrix} -1 \\ 2 \\ -1 \end{pmatrix} \\
 \boxed{G_{W^\perp} = [\psi_1, \psi_2] \quad \psi_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}, \quad \psi_2 = \frac{1}{\sqrt{6}} \begin{pmatrix} -1 \\ 2 \\ -1 \end{pmatrix}}
 \end{aligned}$$

Therefore, next we calculate norm  $V_2$  squared which is  $1^2 + 2^2 + 1^2 = 6$  and then  $\sqrt{6}$  so, the  $1^2 + 2^2 + 1^2$  squared has been pulled out now, if you divide  $V_2$  by norm  $V_2$  we get  $\psi_2$  which is the second vector in the orthonormal base. So, we get  $G_{W^\perp}$  to be  $\psi_1$  which is equal to  $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$  and then  $\psi_2$  which is  $\frac{1}{\sqrt{6}} \begin{pmatrix} -1 \\ 2 \\ -1 \end{pmatrix}$  so, thus we have the orthonormal basis for  $W^\perp$  so,  $\psi_1$  was our orthonormal basis for this is the orthonormal basis for  $W$  and now we have the orthonormal basis for  $W^\perp$ .

(Refer Slide Time: 21:15)

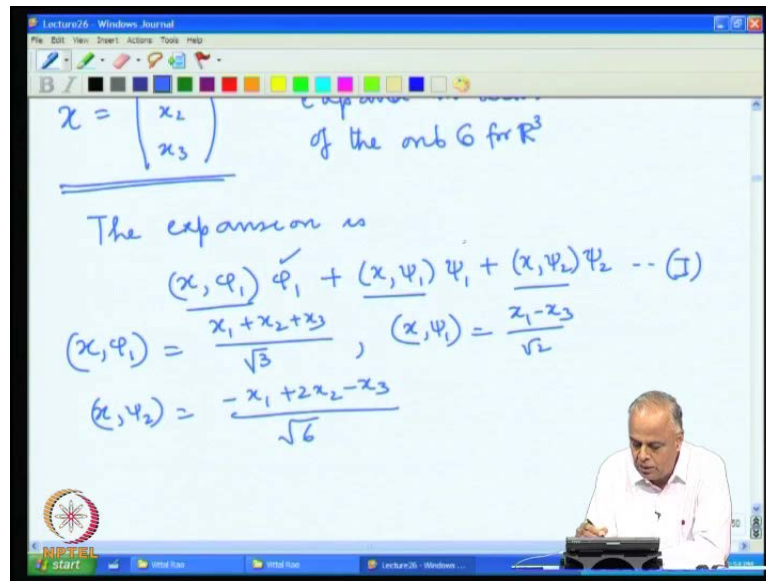

$$\begin{aligned}
 G &= G_W \cup G_{W^\perp} \\
 &= \{\psi_1, \psi_2, \psi_3\} \\
 &\text{is an o.n.b. for } \mathbb{R}^3 \\
 x &= \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \quad \text{Expand in terms of the onb } G \text{ for } \mathbb{R}^3
 \end{aligned}$$

Now, if you put these two together  $o$  equal to  $ow$  union  $ow$  perp which gives me  $\phi_1$   $\psi_1$  and  $\psi_2$  this is an orthonormal basis for  $R^3$ . So, it is easy to check they are orthonormal and there are three vectors and therefore, they will form an orthonormal basis thus, we see that if you put together an orthonormal basis for  $W$  and an orthonormal basis for  $W$  perp you always end up with an orthonormal basis for the whole space.

Now let us take any vector  $x$  we are now going to look at the splitting of the vector we has now seen the splitting of the basis, we have seen the splitting of the orthonormal basis and now, we are going to look at the splitting of the  $x$ . The basis was split into the part in  $W$  and the part in  $W$  perp the orthonormal basis was split into the orthonormal basis part of  $W$  and the orthonormal basis for  $W$  perp. Now, we are going split the vector  $x$  into the part in  $W$  another part in  $W$  perp. Let us look at that splitting so, we have  $x$  we can expand this in terms of this basis  $o$  so, expand in terms of the orthonormal basis  $o$  for  $R^3$ . Now, how do I get the orthonormal basis the expansion is we know that whenever we have an orthonormal basis the expansion is  $x$  comma  $\phi_1$   $\phi_1$  the coefficient of the  $\phi_1$  vector is at the dot product of  $x$  with  $\phi_1$ .

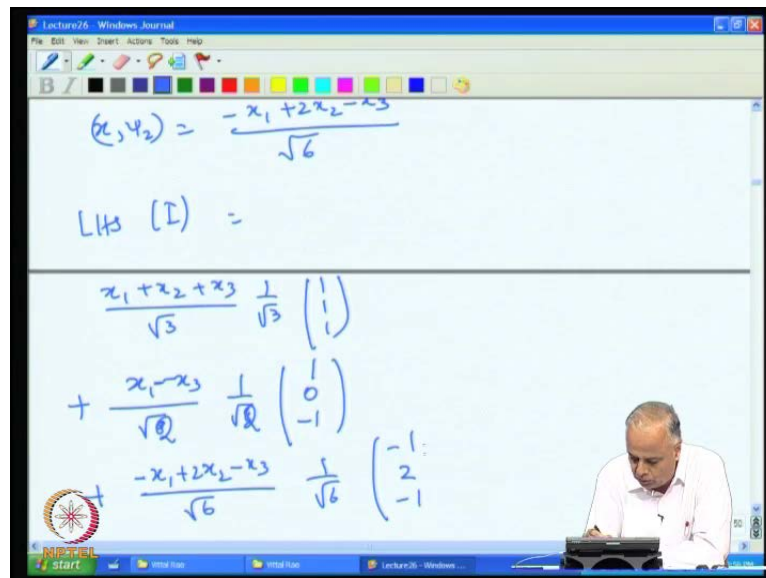

Similarly ,the coefficient of the  $\psi_1$  vector is the dot product with  $\psi_1$  the coefficient of the  $\psi_2$  vector is the dot product with  $\psi_2$ . Let us find each 1 of these numbers so let us call this as 1 what is  $x \cdot \phi_1$ ?  $x \cdot \phi_1$  we have  $\phi_1$  is this vector  $\frac{1}{\sqrt{3}}$  into  $(1, 1, 1)$  so, if a dot product  $x$  with that I get  $x_1$  plus  $x_2$  plus  $x_3$  by root 3 next, what is  $x \cdot \psi_1$ ? we have  $\psi_1$  is this vector  $\frac{1}{\sqrt{2}}$  into  $(1, 0, -1)$ .

(Refer Slide Time: 24:13)

And therefore, if a dot product with that we will get  $x_1$  minus  $x_3$  by root 2 and what is  $x$  psi 2? again with dot product with that vector psi 2  $1/\sqrt{6}$  into  $[-1, 2, 1]$  so, we get  $-x_1 + 2x_2 - x_3$  by root 6. If you substitute these values here  $x$  phi 1  $x$  psi 1  $x$  psi 2 and we know what phi 1 is and what psi 1 is and what psi 2 is.

(Refer Slide Time: 24:55)

So therefore, the LHS of 1 becomes  $x$  by 1 which is  $x_1 + x_2 + x_3$  by root 3 into phi 1  $1/\sqrt{3}$ . Then plus the  $x$  psi 1 which is  $x_1 - x_3$  by root 2 into  $1/\sqrt{2}$  into  $[-1, 0, 1]$ , which is the  $x$  psi 2  $1/\sqrt{6}$  the last one is  $x$  psi 3  $x$  psi 2  $1/\sqrt{6}$  this will

be  $1 \ 0 \ -1$  and this will be  $1 \ \text{by} \ \sqrt{2} \ 1 \ \text{by} \ \sqrt{2}$ . Then, the last  $1$  is  $x \ \psi_2 \ \psi_2$  which gives me the root  $6$  which is  $-x_1 \ \text{plus} \ 2x_2 \ \text{minus} \ x_3$  by root  $6$  into  $1 \ \text{by} \ \sqrt{6}$  into  $-1 \ 2 \ -1$ . If you simplify this becomes I will write this part separately and this part separately because, the first part here belongs to  $W$  and this part belongs to  $W^\perp$  because  $\psi_1$  and  $\psi_2$  this  $\psi_1$  and  $\psi_2$  belong to  $W^\perp$  this linear combination belong to  $W^\perp$ .

(Refer Slide Time: 26:33)

The image shows a whiteboard with handwritten mathematical work. At the top, there is a vector expression:  $\left\{ + \frac{-x_1 + 2x_2 - x_3}{\sqrt{6}} \frac{1}{\sqrt{6}} \begin{pmatrix} 2 \\ -1 \end{pmatrix} \right\}$ . Below this, the vector is decomposed into two parts:  $= \begin{pmatrix} (x_1 + x_2 + x_3)/3 \\ (x_1 + x_2 + x_3)/3 \\ (x_1 + x_2 + x_3)/3 \end{pmatrix} + \begin{pmatrix} (2x_1 - x_2 - x_3)/3 \\ (-x_1 + 2x_2 - x_3)/3 \\ (-x_1 - x_2 + 2x_3)/3 \end{pmatrix}$ . The first part is labeled  $x_W$  and the second part is labeled  $x_{W^\perp}$ . Finally, the entire expression is equated to  $x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$ .

And since this vector belongs to  $W$  that part will belong to  $W$  so, we will just write it as  $x_1 \ \text{plus} \ x_2 \ \text{plus} \ x_3 \ \text{by} \ 3 \ x_1 \ \text{plus} \ x_2 \ \text{plus} \ x_3 \ \text{by} \ 3 \ x_1 \ \text{plus} \ x_2 \ \text{plus} \ x_3 \ \text{by} \ 3$  plus, If you now, simplify the other part you are going to obviously get  $2 \ x_1 \ \text{minus} \ x_2 \ \text{minus} \ x_3 \ \text{by} \ 3$  minus  $x_1 \ \text{plus} \ 2x_2 \ \text{minus} \ x_3 \ \text{by} \ 3$  and then, minus  $x_1 \ \text{minus} \ x_2 \ \text{plus} \ 2x_3 \ \text{by} \ 3$  and when you add you get equal to  $x$ . So, thus we have the vector  $x$  has been split into two parts this part is the  $x_W$  and this part the  $x_{W^\perp}$  so, every vector  $x$  can be split into two parts one part belong to the  $W$  space the other part belonging to the orthogonal complement.

(Refer Slide Time: 27:41)

For example if  $x = \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} \in \mathbb{R}^3$

$x_W = \begin{pmatrix} 2 \\ 2 \\ 2 \end{pmatrix} \in W$

$x_{W^\perp} = \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \in W^\perp$

For example, if  $x$  is equal to 1 2 3 is the vector in  $\mathbb{R}^3$  then, what is  $x_W$  the splitting now, the splitting simply takes the average of the three components and you get 1 plus 2 plus 3 by 3 which is 6 by 3 6 by 3 6 by 3 and  $x_{W^\perp}$  is just minus 1 0 1.

Where these two you observe that this belongs to  $W$  because all the components are equal recall the space  $W$  consists of all the vectors whose all components are equal and this belongs to  $W^\perp$  because it is orthogonal to all the vectors in  $W$ .

(Refer Slide Time: 28:37)

$x = x_W + x_{W^\perp}$

Pythagoras:  $\|x\|^2 = 1^2 + 2^2 + 3^2 = 14$

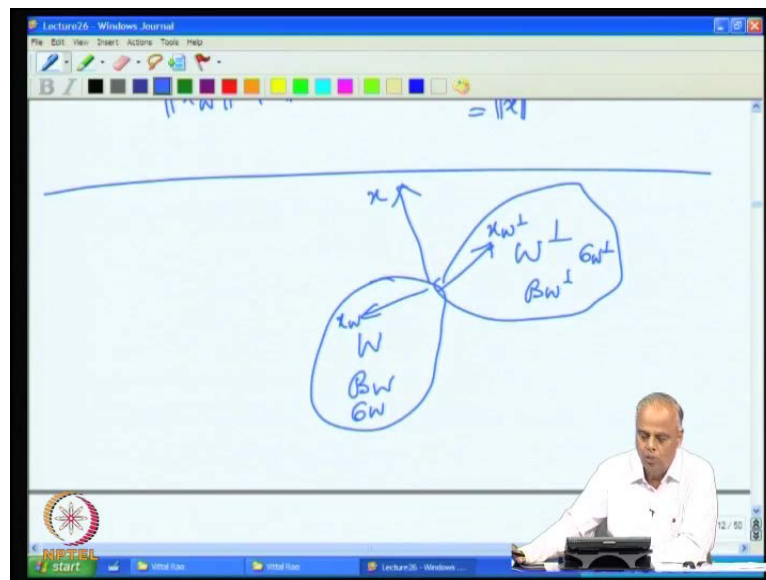

$\|x_W\|^2 = 2^2 + 2^2 + 2^2 = 12$

$\|x_{W^\perp}\|^2 = (-1)^2 + 0^2 + 1^2 = 2$

$\|x_W\|^2 + \|x_{W^\perp}\|^2 = 12 + 2 = 14 = \|x\|^2$

Thus, we see that the vector  $x$  equal to  $1\ 2\ 3$  has been split into  $x_W$  plus  $x_{W^\perp}$ . Let us check the Pythagoras Theorem for this, what is norm of  $x$  squared? Since, the vector  $x$  is  $1\ 2\ 3$  the norm  $x$  squared is  $1$  squared plus  $2$  squared plus  $3$  squared which is  $1$  plus  $4$  plus  $9$  which is  $14$ . On the other hand norm of the length of the  $x_W$  squared  $x_W$  the vector whose components are  $2\ 2$  and  $2$ . So, this length squared will be  $2$  squared plus  $2$  squared plus  $2$  squared which is  $4$  plus  $4$  plus  $4$  which is equal to  $12$  and the length of  $x_{W^\perp}$  squared is  $1$  squared plus  $0$  squared plus  $1$  squared which is  $1$  plus  $1$  which is  $2$  and therefore,  $x_W$  squared plus  $x_{W^\perp}$  squared is equal to  $12$  plus  $2$  which is  $14$  which was the normal  $x$  square this is the one that now verifies the Pythagoras Theorem.

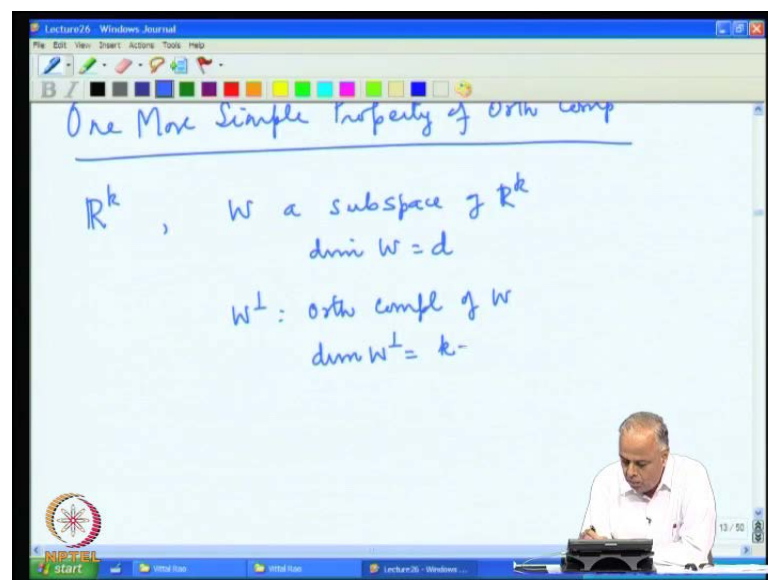

(Refer Slide Time: 30:02)

So, we have therefore, suppose we have a subspace  $W$  in  $R^k$  then there is a subspace  $W^\perp$  which is orthogonal to it and any vector  $x$  can be split into a portion here and a portion there this is the  $x_W$  and this is the  $x_{W^\perp}$  and that is  $x$  any vector  $x$  can be split into two parts and that splitting is unique and the basis can be split into a basis here and a basis there and an orthogonal basis can be split into orthogonal base, which means that in order to study the whole space we can split the study into two parts and the study of  $W$  and the study of  $W^\perp$  because now every vector is split into two parts every basis is split into two parts every orthonormal basis is split into two parts.

Therefore, the vector space is made up of these two pieces the  $W$  and the  $W$  perp knowing  $W$  and  $W$  perp we can analyze the whole space now, given the vector space which is the  $W$  that we choose in order to analyze which subspace we will choose and who whose orthogonal complement we will choose so, that the splitting is useful for us and therefore, the splitting of the vector space in terms of a subspace and its orthogonal complement depends on the problem that we have in hand. Now, we shall focus mainly on the problems connected with matrices and therefore, we shall look at matrices and the orthogonal complements and the subspaces and the orthogonal complements in order to do that, Let us first look one more simple property of orthogonal complements..

(Refer Slide Time: 31:59)

So, let us look at one simple property of orthogonal complements so, let us take  $R^k$  and  $W$  a subspace of  $R^k$  say dimension of  $W$  is equal to  $d$  let us say the dimension of  $W$  is equal to  $d$ . Then  $W$  perp is the orthogonal complement of  $W$  then we have seen the dimension of  $W$  plus dimension of  $W$  perp is the dimension of the whole space so, the dimension of  $W$  perp must be the  $k$  minus  $d$ .

(Refer Slide Time: 33:00)

$X = W^\perp$        $X$  is a subspace  
 $\dim X = k - d$

$X^\perp$  orth. comp. of  $X$   
 $= \{x \in \mathbb{R}^k : (x, y) = 0 \forall y \in X = W^\perp\}$

Now, look at the subspace  $W$  perp let me call  $X$  as  $W$  perp. Now,  $X$  is a subspace dimension of  $X$  is  $k$  minus  $d$ , since  $X$  is a subspace we can talk about  $X$  perp;  $X$  perp orthogonal complement of  $X$ . This is the set of all vectors  $X$  in  $\mathbb{R}^k$  such that  $x \cdot y$  is equal to 0 for every  $y$  in  $X$  which is  $X$  is  $W$  perp. So, in other words  $X$  perp is the set of all the vectors which are orthogonal to all the vectors in  $W$  perp.

(Refer Slide Time: 33:58)

Clearly  $x \in W \Rightarrow x \in X^\perp$   
 $W \subseteq X^\perp$

$\dim X + \dim X^\perp = \dim \mathbb{R}^k$   
 $\dim W^\perp + \dim (W^\perp)^\perp = \dim \mathbb{R}^k$   
Also have  $\dim W^\perp + \dim W = \dim \mathbb{R}^k$

Clearly  $x$  belongs to  $W$  implies  $x$  belongs to  $X$  perp because, every vector in  $W$  is orthogonal to every vector in  $W$  perp and therefore, we have  $W$  is contained or equal to  $X$  perp. So, that is one thing we observe.

Also the dimension of  $X$  plus dimension of  $X$  perp whenever you take a subspace and its orthogonal complement the dimensions add up to the dimension of  $R^k$  so, this says dimension of  $W$  perp because  $X$  is  $W$  perp plus dimension of  $W$  perp perp  $X$  is  $W$  perp so,  $X$  perp perp is  $W$  perp perp is equal to dimension of  $R^k$ . We also have dimension of  $W$  perp plus dimension of  $W$  is equal to dimension of  $R^k$  because, again the dimension of subspace plus its dimension, of its orthogonal complement will be equal to the dimension of the whole space.

(Refer Slide Time: 35:16)

The whiteboard content is as follows:

$$W \subseteq X^\perp \quad \leftarrow \quad W \subseteq (W^\perp)^\perp$$

$$\dim X + \dim X^\perp = \dim R^k$$

$$\dim W^\perp + \dim (W^\perp)^\perp = \dim R^k$$

Also have

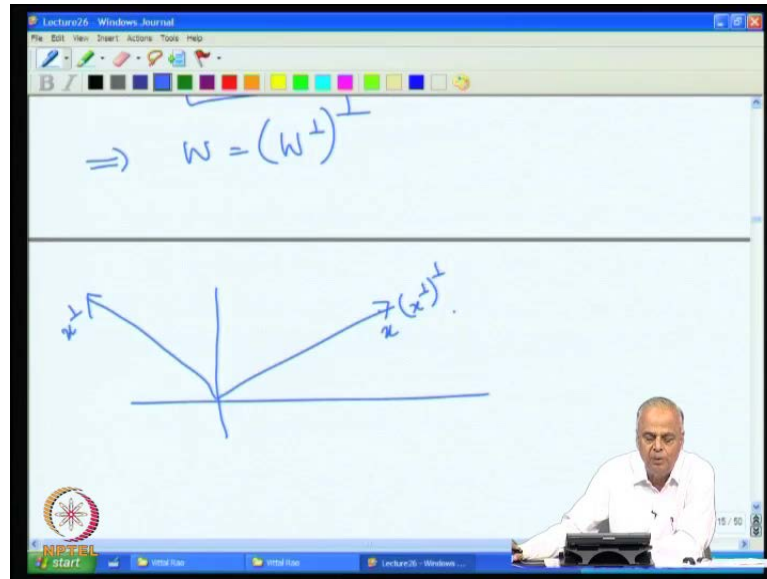

$$\dim W^\perp + \dim W = \dim R^k$$

$$\Rightarrow \dim W = (\dim W^\perp)^\perp$$

$$\Rightarrow W = (W^\perp)^\perp$$

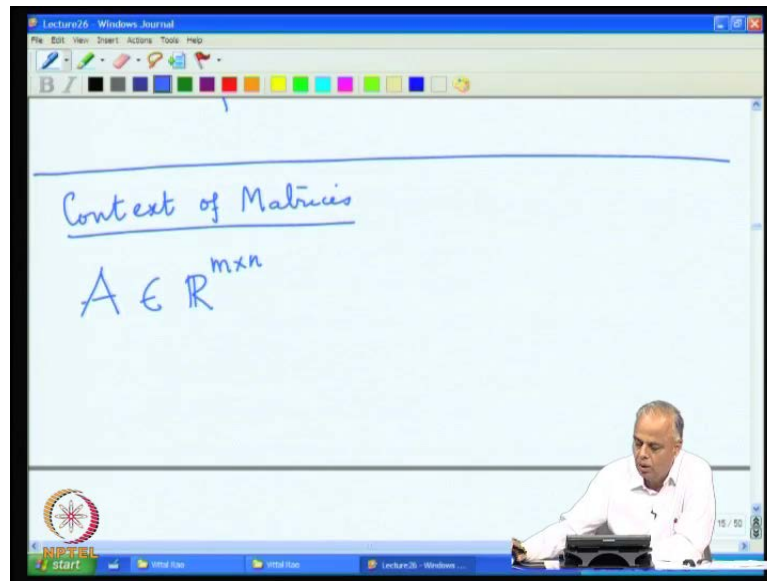

Now, compare these two we find that the dimension of  $W$  is equal to the dimension of  $W$  perp perp. Now,  $W$  is a **sub**space is contained in  $X$  perp,  $X$  perp is nothing but  $W$  perp. perp. So,  $W$  is contained in  $W$  perp perp, but its dimension is the same as  $W$  perp perp so, the two together says  $W$  equal to  $W$  perp perp, so the second perp is the original space.

(Refer Slide Time: 35:59)

This is akin to the fact that suppose I take  $L$  vector and I take a vector which is perpendicular to it again I take the perpendicular to this I get back to this original vector so, this is  $x$  this is  $x$  perp and this is  $x$  perp perp so, we do double perpendicular you get back to the original one and that is exactly what is being observed here in the general context the  $W$  perp perp is equal to  $W$ . Now, as we mentioned that all these decompositions you will have to study with respect to a particular problem given the problem what is the  $W$ , we must choose and therefore, the corresponding  $W$  perp then split the problem into two parts by splitting the space, by splitting the basis, by splitting the orthonormal basis, and by splitting the vectors, and therefore, a priori thing is what is the subspace that we should choose in order to splitting and now, we will analyze this in the context of matrices.

(Refer Slide Time: 37:07)

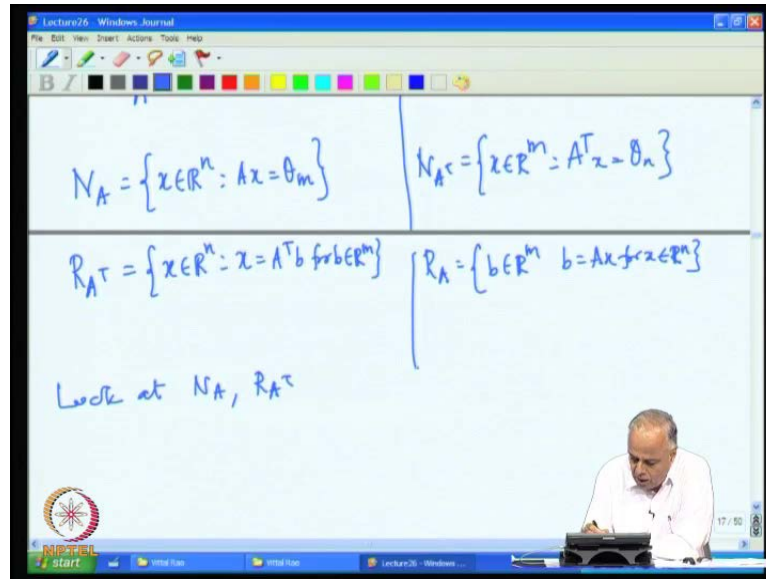

Hold the splitting has to be analyzed in the context of matrices so, let us now consider  $A$  to be an  $m$  by  $n$  matrix. We have seen that with every matrix we can associate four important fundamental subspaces.

(Refer Slide Time: 37:35)

The four fundamental subspaces, there are two subspaces of  $\mathbb{R}^n$  and two subspaces of  $\mathbb{R}^m$  if  $A$  is an  $m$  by  $n$  matrix they will be two subspaces of  $\mathbb{R}^n$  so, we have  $\mathbb{R}^n$  on this side and we have  $\mathbb{R}^m$  on this side and  $A$  it takes  $n$  vectors to  $m$  vectors.

(Refer Slide Time: 38:06)

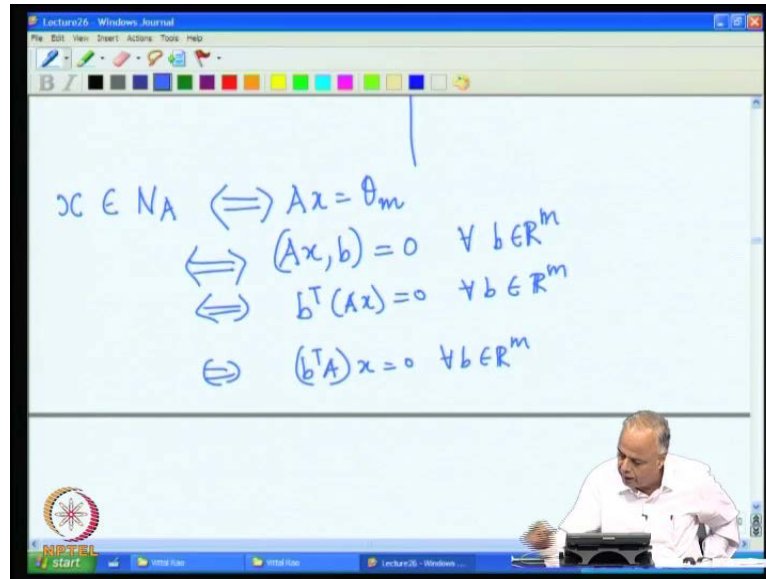

Now we are going to get two subspaces on the  $R^n$  side the two subspaces that we had where the range of  $A$  transpose and the null space of  $A$ . The range of  $A$  transpose and the null space of  $A$  where subspaces of  $R^n$  and similarly, there were two subspaces on the  $R^m$  side they were the range of  $A$  and the null space of  $A$  transpose.

What are these subspaces? the null space of  $A$  is the set of all vectors in  $R^n$  which get mapped with the  $0$  vector under this transformation, and  $R_{A^T}$  is the set of all vectors in  $R^n$  such that  $x$  is of the form  $A^T b$  for  $b$  in  $R^m$ . It is the image of some vector the range is it consider a vector  $x$  which is the image of some vector under the transformation  $A^T$ . On the other hand in the  $R^m$  side they have  $N_{A^T}$  which is the set of all vectors in  $R^m$  such that  $A^T x$  is equal to  $0$  and  $R_A$  will be set of all vectors  $b$  in  $R^m$ . Such that  $b$  is equal to  $Ax$  for  $x$  in  $R^n$ . these now, the image of  $A$ . So,  $R_{A^T}$  is the image of the function  $A^T$  as a function from  $R^m$  to  $R^n$   $R_A$  is the image of the function  $A$  as a function from  $R^n$  to  $R^m$ .

Now let us look at the pair  $N_{A^T}$   $R_{A^T}$  which is in  $R^n$  whatever we do analogous results we will get on the  $R^m$  side.

(Refer Slide Time: 40:17)

Now therefore, we are going to look at the subspaces  $N_A$  and  $R_{A^T}$  transpose on the  $\mathbb{R}^n$  side. Suppose a vector  $x$  belongs to the null space of  $A$  this can happen if and only if  $Ax$  equal to  $0_m$  this is what is meant by saying that  $x$  is the null space of  $A$  that means  $x$  get annihilated by the matrix  $A$ .

Now if  $Ax$  is the  $0$  vector the only way something can be  $0$  vector is it is orthogonal to all the vectors. Since, it is  $0$  vector on the  $\mathbb{R}^m$  side it must be orthogonal to all the vectors on the  $\mathbb{R}^m$  side that means its dot product with all the vectors on the  $\mathbb{R}^m$  side must be  $0$ . So,  $(Ax, b)$  must be equal to  $0$  for every  $b$  in  $\mathbb{R}^m$  but what is the definition of the dot product? it is  $b^T Ax$  must be equal to  $0$  for every  $b$  in  $\mathbb{R}^m$  this means  $b^T Ax$  equal to  $0$  for every  $b$  in  $\mathbb{R}^m$  because, matrix multiplication is associative we can group them as we want, we can write this as  $(b^T A)x$  equal to  $0$  for every  $b$  in  $\mathbb{R}^m$ .

(Refer Slide Time: 41:39)

$\Leftrightarrow (b^T A)x = 0 \quad \forall b \in \mathbb{R}^n$   
 $\Leftrightarrow (A^T b)^T x = 0 \quad \forall b \in \mathbb{R}^m$   
 $\Leftrightarrow (x, A^T b) = 0 \quad \forall b \in \mathbb{R}^m$   
 $\Leftrightarrow x$  ortho to all vectors of the form  $A^T b, b \in \mathbb{R}^m$   
 $\Leftrightarrow x$  is ortho to all vect in  $R_{A^T}$   
 $\Leftrightarrow x \in R_{A^T}^\perp$

So, what this says is  $x$  is orthogonal to all the vectors of the form  $A$  transpose  $b$  so,  $x$  comma  $A$  transpose  $b$  is equal to 0 for every  $b$  in  $\mathbb{R}^m$ . That is if  $x$  is orthogonal to all vectors of the form  $A$  transpose  $b$ ,  $b$  belonging to  $\mathbb{R}^m$  but if you now look at the definition of the range of  $A$  transpose that is precisely the definition the vectors in the range of  $A$  transpose are all vector to the form  $A$  transpose  $b$  and therefore, this means  $x$  is orthogonal to all vectors in range of  $A$  transpose which means  $x$  belongs to range of  $A$  transpose **perpendicular** thus we see that the null space of  $A$  is the same as range of  $A$  transpose perpendicular.

(Refer Slide Time: 42:51)

$N_A = R_{A^T}^\perp$	$N_{A^T} = R_A^\perp$
$N_A^\perp = R_{A^T}$	$N_{A^T}^\perp = R_A$
$\mathbb{R}^n$	$\mathbb{R}^m$

$\dim R_{A^T} + \dim R_{A^T}^\perp = n$   
 $\rho_{A^T} + \nu_A = n$

Since, the perp of the perp is itself we get  $NA^\perp$  is  $RA^T$  transpose perp perp which is equal to  $RA^T$  analogous to this, on the other side we get  $NA^T$  is the range of  $A^\perp$  and  $NA^T$  is the range of  $A$  so, this is on the  $R^n$  side and this is the  $R^m$  side.

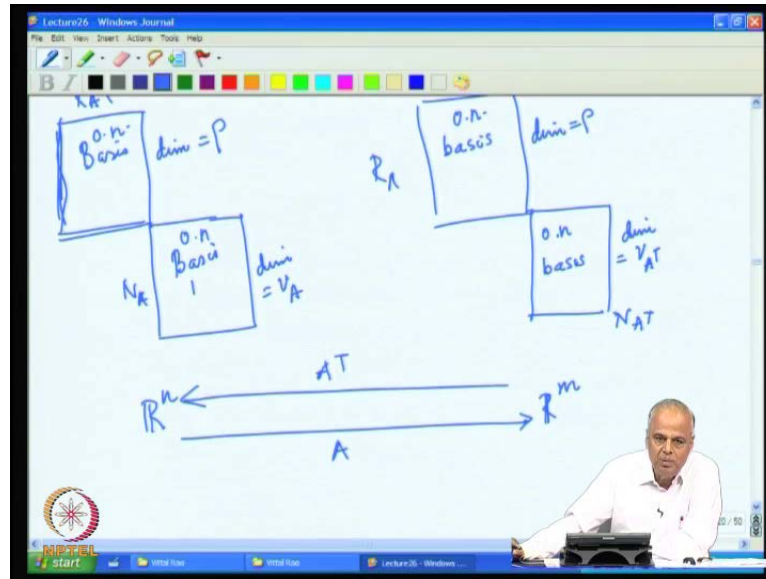

Now, what does this mean ? we have dimension of range of  $A^T$  plus dimension of range of  $A^\perp$ . Whenever we take a subspace and its orthogonal complement and we look at the dimensions and their sum it must give me the dimension of the whole space these are all subspaces in  $R^n$  therefore, the dimension of the whole space  $n$  that must be equal to  $n$ . Now, the dimension of range of  $A^T$  is what we call as the rank of  $A^T$  and therefore, dimension of  $RA^T$  perpendicular is  $n - \text{rank}(A^T)$  and therefore, dimension of  $RA^T$  perpendicular is dimension of  $NA$  dimension of  $NA$  is what we call as a nullity of  $A$  and therefore, rank of  $A^T$  plus nullity of  $A$  is equal to  $n$ .

(Refer Slide Time: 44:28)

On the other hand Rank Nullity Theorem gives the rank of  $A$  plus nullity of  $A$  is equal to  $n$  now, compare these two we get rank of  $A$  is equal to rank of  $A^T$  and therefore, we have an important conclusion that for any matrix over the real numbers rank its rank is equal to the rank of its transpose. So, the matrix and its transpose have the same rank and secondly, the spaces are all orthogonal to each other therefore, the structure is as follows.

(Refer Slide Time: 45:29)

We have  $\mathbb{R}^n$  on the one side  $\mathbb{R}^m$  on the other side  $A$  takes these vectors  $n$  vectors to  $m$  vectors  $A$  transpose takes  $m$  vectors to  $n$  vectors on the  $\mathbb{R}^n$  side we have two subspaces the range of  $A$  transpose and the null space of  $A$  and they are orthogonal to each other that is the thing we have found so far, on this side we have the null space of  $A$  transpose and the range of  $A$  which is the and these two are orthogonal to each other.

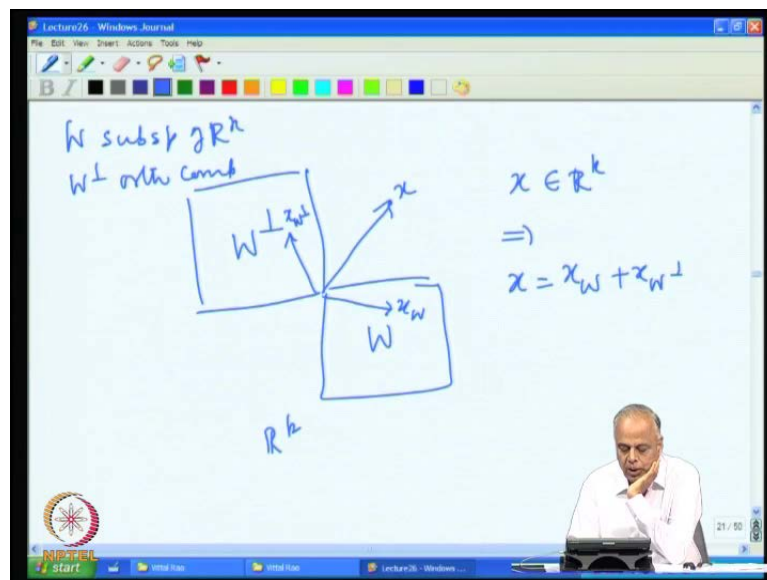

So, we have four subspaces two pairs, one pair in  $\mathbb{R}^n$  and this pair is called orthogonal complements of each other another pair in  $\mathbb{R}^m$  and this pair is also orthogonal complement of each other. Therefore, we have two pairs of orthogonal complements of each other and the main idea in analyzing a matrix is to get a suitable basis for  $R_A$  transpose, a suitable basis for  $N_A$ . Now, by our analysis we know that if we get a basis for these two orthogonal fellows one being orthogonal complement of the other by putting them together we can get basis for the whole space.

So therefore, finding a basis for  $\mathbb{R}^n$  is converted into the problem for a suitable basis for  $R_A$  transpose and a suitable basis for  $N_A$  and we would even look for orthonormal basis and similarly, we would look for orthonormal basis here and the orthonormal basis here and notice that because the dimension of the range of  $A$  transpose equal to dimension of range of  $A$  or the rank of  $A$  transpose is the rank of  $A$ ,  $R_A$  transpose and  $R_A$  have the same dimension which we will call as  $\rho$ . Since,  $\rho_A$  equal to  $\rho_{A^T}$  we will not put the suffix  $A$  and  $A$  transpose we will simply call it as  $\rho$  the rank of the matrix

and the dimension here is also rho the dimension here is the nullity of A and the dimension here is the nullity of A transpose.

So therefore, the main analysis of the matrix will boil down to finding suitable orthonormal basis for these four pieces of subspaces two subspaces on the  $\mathbb{R}^n$  side and two subspaces on the  $\mathbb{R}^m$  side and it is this analysis of finding a suitable basis, a suitable orthonormal basis which will occupy our attention for almost the rest of the course. therefore, we have to understand what is meant by a suitable basis, how to choose this orthonormal suitable basis, how you put all this information together to get the answers to all the questions that we raised about a matrix. Now, before we do that let us also observe one fact.

(Refer Slide Time: 49:10)

Suppose, I have a  $\mathbb{R}^k$  and I have a subspace  $W$  and I have an orthogonal complement  $W^\perp$ , we said that if you take a vector  $x$  in the space it can be split into two parts  $x_W$  and  $x_{W^\perp}$ . Therefore,  $x$  belongs to  $\mathbb{R}^k$  so, we have  $W$  subspace of  $\mathbb{R}^k$  and  $W^\perp$  orthogonal complement then  $x$  belongs to  $\mathbb{R}^k$  implies  $x$  can be written as  $x_W$  plus  $x_{W^\perp}$ .

Now what is this role of this  $x_W$ ? Suppose now, we have this vector  $x$  and we do not have any information of  $W^\perp$  and therefore, we would like to get as much information about  $x$  from  $W$  alone.

(Refer Slide Time: 50:26)

$\mathbb{R}^k$

Given  $x$  find a vector  $w_0 \in W$  s.t.

$$\|x - w_0\|^2 < \|x - w\|^2 \quad \forall w \neq w_0, w \in W$$

---

Approximation Problem

$\mathbb{R}^k$ ,  $W$  subspace of  $\mathbb{R}^k$

What this means is given  $x$  find a vector which we will call as  $w_0$  in  $W$  such that if you now look at the suppose, I take  $w_0$  as the approximation for  $x$  then the error is  $x$  minus  $w_0$  and the quantification of the error squared is the length squared so this is the error by taking  $w_0$  as the approximation of  $x$ .

Now, I want to find a  $w_0$  such that that is the least error that is if you take any other  $w$  in  $W$  the error must be more  $x$  minus  $w_0$  must be giving the least error. So, in other words can we approximate  $x$  in  $W$  with the least error so, this is called the approximation problem. So, approximation problem is the following  $\mathbb{R}^k$  and then we have  $W$  subspace of  $\mathbb{R}^k$ .

(Refer Slide Time: 52:00)

$\mathbb{R}^k$ ,  $W$  subspace of  $\mathbb{R}^k$

Given  $x \in \mathbb{R}^k$  find  $w_0 \in W$

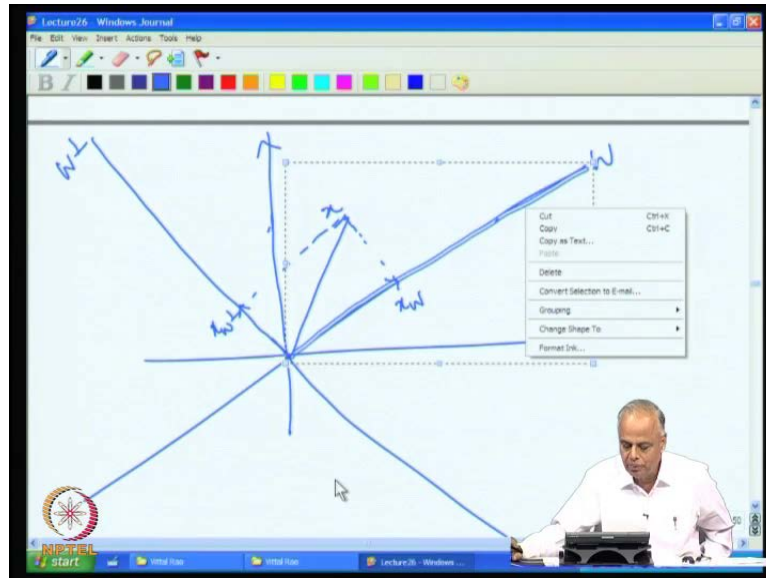

s.t.  $\|x - w_0\|^2 < \|x - w\|^2 \quad \forall w \in W, w \neq w_0$

The vector  $w_0$  which gives this least error for  $x$  is precisely  $x_W$  — the orthogonal proj of  $x$  onto  $W$ .

Then given  $x$  in  $\mathbb{R}^k$  find  $w_0$  in  $W$  such that if we take  $w_0$  as the approximation for  $x$  the error length of the error squared is less than the error for any other vector in  $W$ . This is called the actually we will call it the best approximation problem because any other vector can do only a worst job because the error will be more here we are trying to minimize the error.

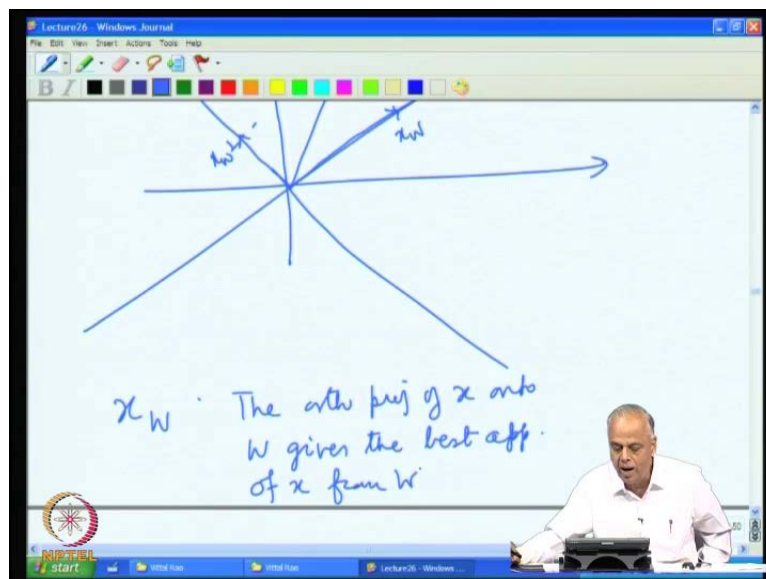

Now, we will see that the vector  $w_0$  we do not even know that whether there is a solution for this problem. We shall see in the next lecture that the vector  $w_0$  which gives this least error for  $x$  is precisely  $x_W$  the orthogonal projection the orthogonal projection of  $x$  onto  $W$ .

(Refer Slide Time: 53:27)

You can visualize this as follows, suppose, we look at two dimensions and we have a subspace a subspace in two dimensions is a line through the origin and then you take any vector  $x$ . Now, what is orthogonal complement of  $W$  it is that perpendicular line so that is  $W$  perp now, take any vector  $x$  what is it splitting this is the orthogonal projection that is drop the perpendiculars this vector is  $x_W$  and this vector is  $x_W$  perp. If you see if you take any vector on the line  $w \in W$  its distance from  $x$  will be more than the perpendicular distance this geometric fact is what we are trying to prove in the theorem.

(Refer Slide Time: 54:32)

So, we find that the orthogonal projection  $x_W$  perp  $x_W$  the orthogonal projection of  $x$  onto  $W$  gives the best approximation of  $x$  from  $W$  so, if this simple geometric fact is

what we are going to approximate and now this fact will be used eventually when we are analyzing these matrices. Recall that when we had a vector  $b$  for which we could not find a solution that will be because it will lie outside the range of  $A$  then  $Ax = b$  will not have a solution then, what we will do is we find the closest vector to  $b$  in  $RA$  and that closest vector being in the range will have a solution and that will generate the notion of the so, called least square solutions, so these are some of the ideas that will be utilized in analyzing the matrix problem.

In the next lecture we would look at in detail, and get exactly this idea of this best approximation and show that these best approximations are given by this orthogonal projection. Then our main problem will be focussed about finding the suitable basis for the four subspaces. We should analyze what sort of basis will make our work of answering the questions regarding the matrix, the fundamental questions that work must become easier by the choice of our basis, we shall work a strategy towards that direction.
