$$g_j = \dim W_j \quad \text{geometric mult. of } \lambda_j$$

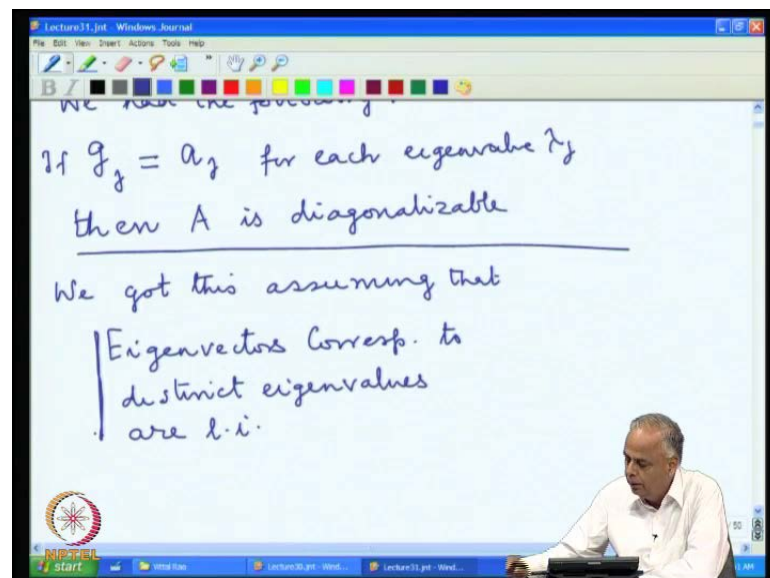

---

We had the following result.  
If  $g_j = a_j$  for each eigenvalue  $\lambda_j$ .

The slide also features a toolbar with drawing tools and a small inset image of the lecturer, Prof. R. Vittal Rao, in the bottom right corner.

We have been looking at the notion of diagonalizability and we found that, if  $A$  is an  $n$  by  $n$  matrix, then the characteristic polynomial was defined as the determinant of  $\lambda I - A$ . We found that this is a polynomial of degree  $n$ . Since we have assumed everything of over the field of complex numbers, this can always be factorised as  $(\lambda - \lambda_1)^{a_1} (\lambda - \lambda_2)^{a_2} \dots (\lambda - \lambda_k)^{a_k}$ . The  $\lambda_1, \lambda_2$  and  $\lambda_k$  are the distinct roots of the polynomials and they are the distinct eigen values of  $A$ .  $a_1, a_2$  and  $a_k$  are called the algebraic multiplicity of these eigen values; of these eigen values  $\lambda_1, \lambda_2$  and  $\lambda_k$ . Then, corresponding to these eigen values, we define the eigen space corresponding to  $\lambda_j$  as the null space of  $A - \lambda_j I$  and the dimension **respond** to be all as greater than or equal to 1. This dimension of  $W_j$  is what we denoted by  $g_j$  and this was called the geometric multiplicity of  $\lambda_j$ .

(Refer slide Time: 04:10)

The screenshot shows a whiteboard with the following content:

Ex 1      $A = \begin{pmatrix} 1 & -3 & 3 \\ -2 & 0 & 2 \\ 1 & -1 & 3 \end{pmatrix}$

$C_A(\lambda) = (\lambda - 4)(\lambda - 2)(\lambda + 2)$

$\lambda_1 = 4, \quad a_1 = 1$

$\lambda_2 = 2, \quad a_2 = 1$

$\lambda_3 = -2, \quad a_3 = 1$

The whiteboard also features a toolbar with drawing tools and a small inset image of a man in a white shirt sitting at a desk.

(Refer slide Time: 05:06)

The screenshot shows a whiteboard with the following content:

We found

$W_1 = \left\{ x \in \mathbb{C}^3 : x = \alpha \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}, \alpha \in \mathbb{C} \right\}$

$W_2 = \left\{ x \in \mathbb{C}^3 : x = \beta \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}, \beta \in \mathbb{C} \right\}$

$W_3 = \left\{ x \in \mathbb{C}^3 : x = \gamma \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}, \gamma \in \mathbb{C} \right\}$

The whiteboard also features a toolbar with drawing tools and a small inset image of a man in a white shirt sitting at a desk.

What we observed in the last lecture was, so, we had the following result in the last lecture, which was this. The geometric multiplicity of an eigen value is equal to its algebraic multiplicity and this happens for each eigen value  $\lambda_j$ . So, it is not that  $g_1$  equal to  $a_1$  or  $g_2$  equal to  $a_2$ . For each  $j$ ,  $g_j$  must be equal to  $\lambda_j$ . For if  $g_j$  equal to  $a_j$  for each eigen value  $\lambda_j$ , then  $A$  is diagonalizable. We found that the diagonalizing matrix  $P$  was made up of all eigen vectors along its columns. This was our main result. We got this assuming another result, which we said will prove later. That is, the eigen vectors corresponding to distinct eigen values are linearly independent. We are

not yet proved it. In this lecture, we will eventually get to prove in these results. But, let us look at some examples again to illustrate what we have got. Let us look at the first example. The same matrix which we looked at in the last lecture also, that is  $\begin{pmatrix} 1 & 3 & 3 \\ 2 & 0 & 2 \\ 1 & 1 & 3 \end{pmatrix}$ . In the last lecture, we found that the characteristic polynomial was  $(\lambda - 4)(\lambda - 2)(\lambda + 2)$ . Consequently, the eigen values were  $\lambda_1 = 4$ ,  $\lambda_2 = 2$ ,  $\lambda_3 = -2$  and each root occurs only once. Therefore, the algebraic multiplicity is  $a_1 = 1$  and  $a_2 = 1$  and  $a_3 = 1$ . Again in the last lecture, we found the eigen space corresponding to  $\lambda_1$  was the set of all vectors in  $\mathbb{C}^3$  which were of the form  $x = \alpha \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$  for  $\alpha \in \mathbb{C}$ .  $W_2$  is the set of all vectors in  $\mathbb{C}^3$ , which were of the form  $x = \beta \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$ , for  $\beta \in \mathbb{C}$ .

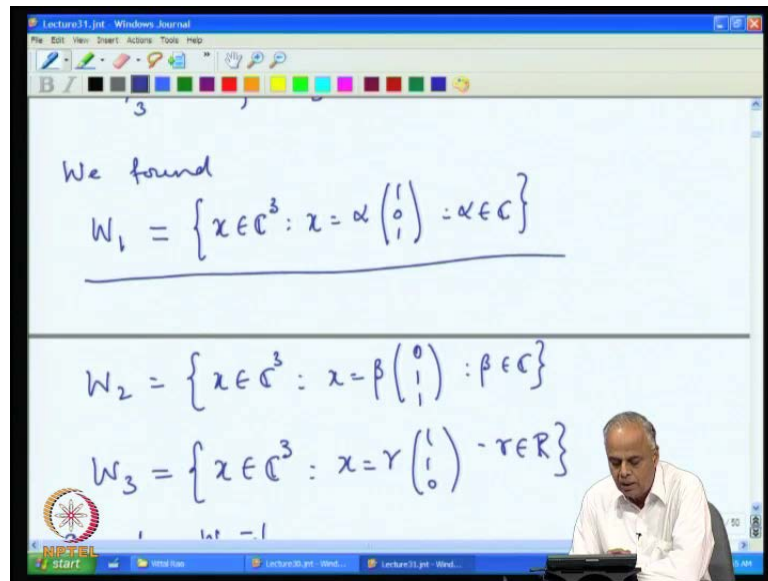

(Refer slide Time: 05:58)

$g_1 = \dim W_1 = 1$   
 $g_2 = \dim W_2 = 1$   
 $g_3 = \dim W_3 = 1$   
 $a_1 = g_1 = 1$   
 $a_2 = g_2 = 1$   
 $a_3 = g_3 = 1$

$\left. \begin{array}{l} a_1 = g_1 = 1 \\ a_2 = g_2 = 1 \\ a_3 = g_3 = 1 \end{array} \right\} \Rightarrow a_m = g_m$   
 for each eigenvalue

Hence  $A$  is diagonalizable.

(Refer slide Time: 07:17)

$w_3$  was found to be the subspace consisting of all those vectors of the form  $\gamma \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}$  and  $\gamma$  belongs to  $\mathbb{R}$ . Now, in this case, we have  $g_1 = 1$ , which is the dimension of  $w_1$  is 1, because  $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$  is the basis for  $w_1$ . Similarly,  $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$  is the basis for  $w_2$ . So, the dimension of  $w_2$  is 1. Similarly,  $\begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}$  is basis for  $w_3$ . So  $g_3$ , the dimension of  $w_3$  is 1. So, in this case, we find that  $a_1$  is the same as  $g_1$  and  $a_2$  is the same as  $g_2$  and  $a_3$  is the same as  $g_3$ . So, the algebraic multiplicity is equal to the geometric multiplicity for each eigen value  $a_i$  equal to  $g_i$ . The algebraic multiplicity is equal to the geometric multiplicity for each eigen value. Hence,  $A$  is diagonalizable. Now, observe that any eigen vector of  $\lambda_1$  is from  $w_1$ . If it takes the eigen space,  $w_1$  corresponding to  $\lambda_1$ , every non zero vector from this place is an eigen vector. So, any eigen vector of  $w_1$  is of the form  $\alpha \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$  and  $\alpha \neq 0$ .

(Refer slide Time: 07:36)

Any eigenvect of  $\lambda_1$  is of the form

$$\begin{pmatrix} \alpha \\ 0 \\ \alpha \end{pmatrix}; \alpha \neq 0$$

Any eigvect of  $\lambda_2$  is of the form

$$\begin{pmatrix} 0 \\ \beta \\ \beta \end{pmatrix}; \beta \neq 0$$

The screenshot shows a whiteboard with handwritten text and equations. The text describes the form of eigenvectors for two eigenvalues,  $\lambda_1$  and  $\lambda_2$ . The equations are written in a clear, legible hand. The whiteboard is part of a presentation software window titled 'Lecture31.ppt - Windows Journal'. A small inset image of a man in a white shirt is visible in the bottom right corner of the whiteboard area.

(Refer slide Time: 08:04)

Any eigvect of  $\lambda_2$  is of the form

$$\begin{pmatrix} 0 \\ \beta \\ \beta \end{pmatrix}; \beta \neq 0$$

Any eigvect of  $\lambda_3$  is of the form

$$\begin{pmatrix} \gamma \\ \gamma \\ 0 \end{pmatrix}$$

The screenshot shows a whiteboard with handwritten text and equations. The text describes the form of eigenvectors for two eigenvalues,  $\lambda_2$  and  $\lambda_3$ . The equations are written in a clear, legible hand. The whiteboard is part of a presentation software window titled 'Lecture31.ppt - Windows Journal'. A small inset image of a man in a white shirt is visible in the bottom right corner of the whiteboard area.

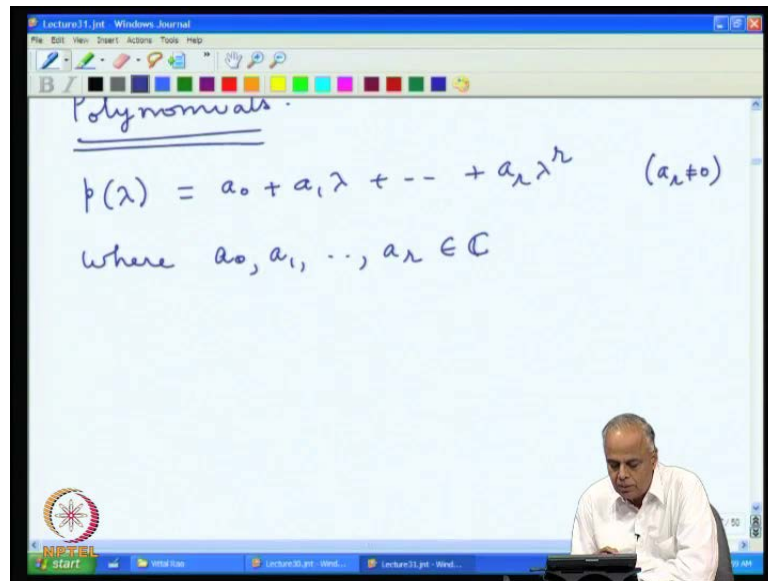

(Refer slide Time: 09:06)

The screenshot shows a Windows Journal window titled "Lecture31.jnt". The window contains handwritten text and a mathematical expression. The expression is  $\begin{pmatrix} \gamma \\ 0 \end{pmatrix}, \gamma \neq 0$ . Below it, the text reads: "These eigenvect. which correspond to distinct eigenvalues can be easily verified to be l.i.". In the bottom right corner, a lecturer is visible, and the NPTEL logo is in the bottom left corner.

(Refer slide Time: 09:36)

The screenshot shows a Windows Journal window titled "Lecture31.jnt". The window contains handwritten text. The text reads: "We shall now look at the process of proving that for  $A \in \mathbb{C}^{n \times n}$  eigenvect. corr. to distinct eigenvalues are l.i.". In the bottom right corner, a lecturer is visible, and the NPTEL logo is in the bottom left corner.

(Refer slide Time: 10:58)

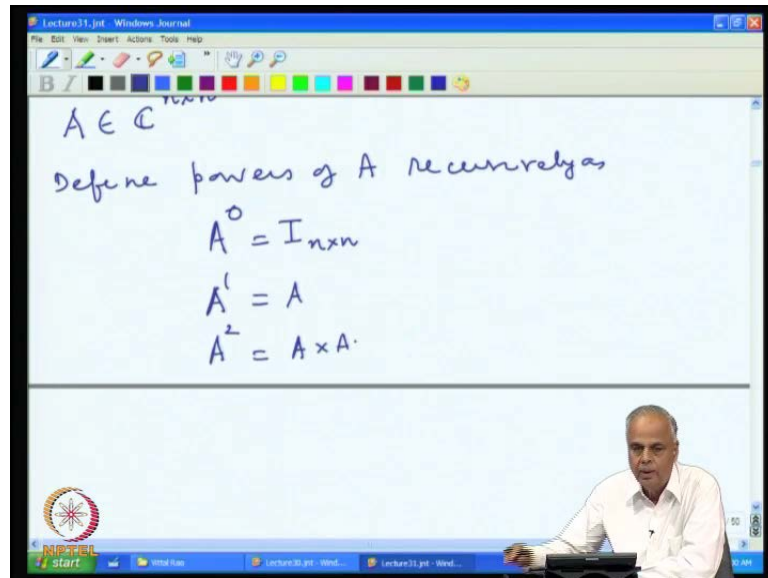

Similarly, any eigen vector of  $\lambda_2$  is of the form  $\begin{bmatrix} 0 \\ \beta \\ \beta \end{bmatrix}$  and  $\beta \neq 0$ . Any eigen vector of  $\lambda_3$  is of the form  $\begin{bmatrix} \gamma \\ \gamma \\ 0 \end{bmatrix}$  and  $\gamma \neq 0$ . Now see, these three eigen vectors, this eigen vector corresponding to  $\lambda_1$ , this eigen vector corresponding to  $\lambda_2$  and this eigen vector corresponding to  $\lambda_3$ , these are eigen vectors corresponding to the distinct eigen values  $\lambda_1$  and  $\lambda_2$  and  $\lambda_3$ . We find they are linearly independent. These eigen vectors which correspond to distinct eigen values can be easily verified to be linearly independent. We know how to verify something is linearly independent. Only linear combination that gives a zero vector is a zero linearly combination. So, easily verified to be linearly independent. This is what we had in mind when we said that distinct eigen vectors corresponding to distinct eigen values are linearly independent.

Now, this is a statement with we have not yet proved. So, we shall embark on proving this fact. So, we shall now look at the process of proving that for a  $n \times n$  matrix, eigen vectors corresponding to distinct eigen values are linearly independent. Now, for this purpose and also for the other purposes, that we may study or you may study and up in advance courses in linear algebra, there are several polynomials that play a crucial role in analysing a matrix. So, the polynomials play very important role in a matrix. There are several polynomials associated with given matrix. We have already seen one polynomial, namely the characteristic polynomial. Analogous to that, there are several other polynomials associated with the matrix. So, we look at in general, to start with some

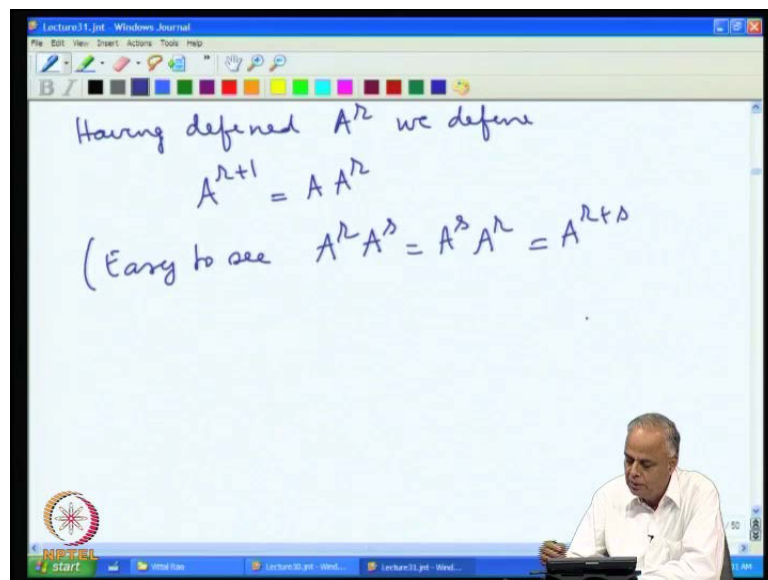

facts about polynomials. These facts are very important in a complete analysis of the structure of matrices and linear transformations in general.

(Refer slide Time: 12:12)

(Refer slide Time: 12:50)

So, we will now consider only polynomials over the complex numbers. So, we always look at a polynomial  $p(\lambda)$ , which is of the form  $a_0 + a_1 \lambda + a_2 \lambda^2 + \dots + a_r \lambda^r$ . We will assume  $a_r \neq 0$ , so that the degree is  $r$ . If only the constant term is there and all other terms are missing, then we will call it the constant polynomial. So, we consider in general polynomials of this type,

where the coefficients  $a_0, a_1, \dots, a_n$  are all complex numbers. So, we are considering polynomials with complex coefficients. Now, the simplest polynomials are like  $\lambda$ ,  $\lambda^2$ ,  $\lambda^3$ , namely the powers of  $\lambda$ . Now, suppose  $A$  is  $n$  by  $n$  matrix, we all know that how to define powers of  $A$ . We define powers of  $A$  recursively, as we define the  $0^{\text{th}}$  power to be the identity matrix, the first power  $A^1$  to be  $A$ ,  $A^2$  to be  $A$  into  $A$ . Now, having defined a power  $r$ , we defined a power  $r+1$  as  $A$  into  $A^r$ . Now, we can easily see that, if  $A^r$  and  $A^s$  are two powers of  $A$ , they commute with each other. So, easy to see,  $A^r$  into  $A^s$  is  $A^{r+s}$  and  $A^s$  into  $A^r$  is equal to  $A^{r+s}$  for any positive integers  $r$  and  $s$ .

(Refer Slide Time: 13:44)

For any given polynomial

$$p(\lambda) = a_0 + a_1 \lambda + \dots + a_n \lambda^n$$

we define

$$p(A) = a_0 I_{n \times n} + a_1 A + a_2 A^2 + \dots + a_n A^n$$

$\in \mathbb{C}^{n \times n}$

(Refer Slide Time: 15:16)

A screenshot of a lecture slide titled "Some Special Polynomials". The slide content is handwritten in blue ink on a white background. It reads: "Some Special Polynomials", " $A \in \mathbb{C}^{n \times n}$ ", and "Let  $\lambda_1, \lambda_2, \dots, \lambda_k$  be the distinct eigenvalues of  $A$ ". The slide is displayed in a window titled "Lecture31.ppt - Windows Journal". A man in a white shirt is visible in the bottom right corner of the frame, looking at a laptop.

(Refer Slide Time: 16:35)

A screenshot of a lecture slide showing a polynomial equation. The slide content is handwritten in blue ink on a white background. It reads: " $p(\lambda) = (\lambda - \lambda_1)(\lambda - \lambda_2) \dots (\lambda - \lambda_k)$ " and "This is monic polynomial of degree  $k$  whose roots are the distinct eigenvalues of  $A$ ". The slide is displayed in a window titled "Lecture31.ppt - Windows Journal". A man in a white shirt is visible in the bottom right corner of the frame, looking at a laptop.

So, we first define the power of a and then, we define for any given polynomial  $p(\lambda)$  equal to  $a^0 + a^1 \lambda + a^2 \lambda^2 + \dots + a^r \lambda^r$ . We defined  $p(a)$ . Now, we are defining a polynomial of the matrix  $a$  as  $a^0 + a^1 a + a^2 a^2 + \dots + a^r a^r$ . In other words, the given polynomial replace each power of  $\lambda$  by the corresponding power of  $a$ . The first term is  $\lambda^0$ . So, we replace it by  $a^0$ , which is identity. Subsequently,  $\lambda$ ,  $\lambda^2$ , we replace them by  $a$ ,  $a^2$  and so on. So, given any polynomial  $p$  with complex coefficients, we associate with it a polynomial in the matrix  $a$ , with complex coefficients. This is again a matrix

which is complex. Start with the complex matrix, complex coefficients, the sum of all the matrices again a matrix and again it could be complex.

So, given any polynomial with complex coefficients, we can always associated with it, the matrix polynomial  $p a$ . Now, we are going to look at some special polynomials. Some special polynomials, that we will work corresponding to the matrix  $a$ . So, we are given the matrix  $a$ . So, we know, we can write on the characteristic polynomials and then, find out all the distinct eigen values. So, let  $\lambda_1, \lambda_2,$  and  $\lambda_k$  be the distinct eigen values of  $a$ . That means, these are the distinct roots of the characteristic polynomial. Now, consider this polynomial  $p \lambda$ , which vanishes at all these points, that is  $\lambda_1, \lambda_2$  and  $\lambda_k$ . So, it has a root  $\lambda_1$ . So, it is  $\lambda - \lambda_1$  must be a factor. It vanishes at  $\lambda_2$ . So,  $\lambda - \lambda_2$  is a factor;  $\lambda - \lambda_k$ .

(Refer Slide Time: 17:20)

of degree  $n$  whose roots are  
the distinct eigenvalues of  $A$   
We now construct

$$\begin{cases} p_1(\lambda) = (\lambda - \lambda_2)(\lambda - \lambda_3) \dots (\lambda - \lambda_k) \\ p_2(\lambda) = (\lambda - \lambda_1)(\lambda - \lambda_3) \dots (\lambda - \lambda_k) \\ \vdots \\ p_k(\lambda) = (\lambda - \lambda_1)(\lambda - \lambda_2) \dots (\lambda - \lambda_{k-1}) \end{cases}$$

(Refer Slide Time: 18:24)

$$p_j(\lambda) = \frac{p(\lambda)}{(\lambda - \lambda_j)} = \prod_{\substack{n=1 \\ n \neq j}}^k (\lambda - \lambda_n)$$

$$j = 1, 2, 3, \dots, k$$

Each of these  $k$  polynomials is a monic poly of degree  $(k-1)$ .

So, this is a polynomial of degree  $n$ , whose roots are  $\lambda_1, \lambda_2, \dots, \lambda_k$  and with polynomial degree of  $k$ , whose roots are  $\lambda_1, \lambda_2, \dots, \lambda_k$ . So, this is a monic polynomial, because the highest power has coefficient 1. This is the monic polynomial of degree  $k$ , because the  $k$  factors, whose roots are the distinct eigen values of  $A$ .  $\lambda_1$  is a root,  $\lambda_2$  is a root and  $\lambda_k$  is a root. Now, what we do is, we construct a lower degree polynomial by removing one factor of this  $k$  factors one at a time.

For example, we now construct  $p_1(\lambda)$ . When I say one, I mean from  $p(\lambda)$  remove the first factor. So, what we get? We do not get  $\lambda - \lambda_1$ . So, we get  $\lambda - \lambda_2, \lambda - \lambda_3, \dots, \lambda - \lambda_k$ . To get the  $p_2(\lambda)$ , from  $p(\lambda)$  we remove the second factor and we look at only  $\lambda - \lambda_1, \lambda - \lambda_3, \dots, \lambda - \lambda_k$ . We continue this process to get  $k$  polynomials. The  $k$ th polynomial, we remove the  $k$ th factor and retain all the other factors.

(Refer Slide Time: 20:02)

The screenshot shows a whiteboard with handwritten mathematical expressions. The top part defines the characteristic polynomial  $p_j(\lambda_n)$  as zero if  $n \neq j$  and as the product of  $(\lambda_j - \lambda_n)$  for  $n=1$  to  $n \neq j$  if  $n=j$ . A note indicates that  $p_j(\lambda_j)$  is the denominator in the next formula. The bottom part shows the Lagrange interpolation formula  $l_j(\lambda) = \frac{p_j(\lambda)}{p_j(\lambda_j)} = \prod_{n=1, n \neq j}^k \frac{(\lambda - \lambda_n)}{(\lambda_j - \lambda_n)}$ . The NPTEL logo is visible in the bottom left corner.

$$p_j(\lambda_n) = 0 \text{ if } n \neq j$$
$$= \prod_{\substack{n=1 \\ n \neq j}}^k (\lambda_j - \lambda_n) \text{ if } n=j$$

(Note:  $p_j(\lambda_j)$  is the denominator in the next formula)

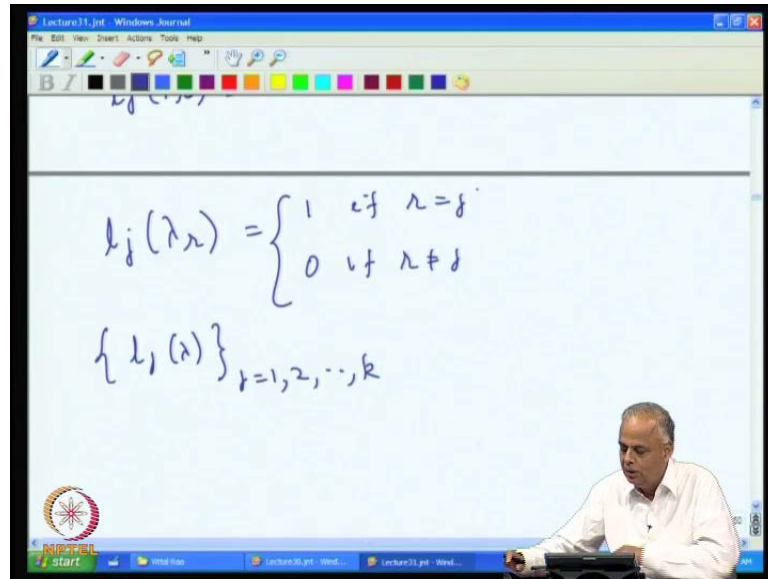

$$l_j(\lambda) = \frac{p_j(\lambda)}{p_j(\lambda_j)} = \prod_{n=1, n \neq j}^k \frac{(\lambda - \lambda_n)}{(\lambda_j - \lambda_n)}$$

(Refer Slide Time: 22:48)

The screenshot shows a whiteboard with handwritten mathematical expressions. The top part shows the Lagrange interpolation formula  $l_j(\lambda) = \frac{p_j(\lambda)}{p_j(\lambda_j)} = \prod_{n=1, n \neq j}^k \frac{(\lambda - \lambda_n)}{(\lambda_j - \lambda_n)}$ . The bottom part shows the properties of the Lagrange basis polynomials:  $l_j(\lambda_j) = 1$  and  $l_j(\lambda_n) = 0$  if  $n \neq j$ . The NPTEL logo is visible in the bottom left corner.

$$l_j(\lambda) = \frac{p_j(\lambda)}{p_j(\lambda_j)} = \prod_{n=1, n \neq j}^k \frac{(\lambda - \lambda_n)}{(\lambda_j - \lambda_n)}$$
$$\left. \begin{array}{l} l_j(\lambda_j) = 1 \\ l_j(\lambda_n) = 0 \end{array} \right\} \text{ if } n \neq j$$

(Refer Slide Time: 23:40)

So, in short form, we will write  $p_j(\lambda)$ , if the polynomial obtained from  $p(\lambda)$  by removing the  $j$ th factor. That means,  $p(\lambda)$  by  $(\lambda - \lambda_j)$ . That factor is cancelled out. We can write this in product notation as,  $\prod_{r=1, r \neq j}^k (\lambda - \lambda_r)$ . So, it takes all factors  $(\lambda - \lambda_r)$ , except the factor  $(\lambda - \lambda_j)$ . Then, we get the polynomial  $p_j(\lambda)$  and we do this for  $j = 1, 2, 3, \dots, k$ . Thus, we get  $k$  polynomials.

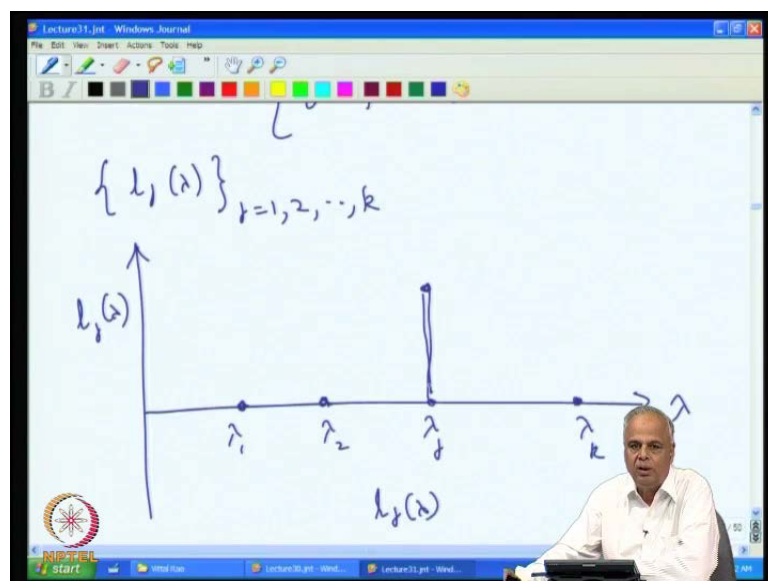

So, each of these  $k$  polynomials is a monic polynomial of degree  $k - 1$  because,  $p(\lambda)$  was of degree  $k$ . Now, we removed one factor, so the degree becomes  $k - 1$ . Now, let us look at this polynomial  $p_j(\lambda)$ . The  $p_j(\lambda)$  has factors,  $(\lambda - \lambda_r)$ , except  $(\lambda - \lambda_j)$  factor. So, if I put  $r = 1$ ,  $(\lambda - \lambda_1)$  is a factor. So,  $\lambda_1$  will be a root and similarly,  $\lambda_2$  will be a root and  $\lambda_3$  will be root. So, all these  $\lambda$ 's will be root, except  $\lambda_j$ . So, we have  $p_j(\lambda_r) = 0$ , if  $r$  is not equal to  $j$ . If  $r$  is not equal to  $j$ , that factor will appear here and therefore,  $p_j(\lambda_r)$  will become 0. But, if  $r$  is equal to  $j$ , what will happen here? We will have  $(\lambda_j - \lambda_r)$ . None of these factors vanish and we get  $r = 1$  to  $k$ ,  $r \neq j$ . It is actually  $p_j(\lambda_j)$ . So, it is actually  $p(\lambda_j)$ . Now, we have these polynomials  $p_j$ , which vanishes at all these points except at the  $\lambda_j$ , where it takes this value. So, this is what  $p_j(\lambda_r)$  is 0. If  $r$  is not equal to  $j$ , so this is  $p_j(\lambda_j)$ . Now, we normalise these polynomials. Suppose, I

define  $l_j(\lambda)$  to be  $p_j(\lambda)$  by  $p_j(\lambda) r$ , what is this polynomial?  $p_j(\lambda)$  is this polynomial, except the  $j$ th term.  $p_j(\lambda) r$  is just this polynomial, where we evaluated at the point, which  $p_j$ . So, what does this become?

We know that these have all the factors. So, let us write it in the factor form. This will be just nothing but, the polynomial  $r$  equal to 1 to  $k$ . Let us look at this as, to make this, sorry, we will make this  $\lambda_j$ . Then, this becomes all the factors.  $\lambda - \lambda_j$  and all the factors  $\lambda_j - \lambda$ . From these two definitions, except the  $\lambda - \lambda_j$ , factor does not appear in the numerator and the  $\lambda_j - \lambda$  factor, do not appear the denominator.

We find that,  $l_j(\lambda_j)$  is  $p_j(\lambda_j)$  by  $p_j(\lambda_j)$ , from the definition is 1 and  $l_j(\lambda_r)$  is  $p_j(\lambda_r)$  by  $p_j(\lambda_r)$  by  $p_j(\lambda_r)$  is 0, if  $r$  not equal to  $j$ .  $l_j(\lambda_r)$  equal to 0, if  $r$  not equal to  $j$ . So, in other words this  $l_j$  is a polynomial. If you keep moving along the  $\lambda_1, \lambda_2$  and  $\lambda_j$  case, it lights up at  $\lambda_j$  and takes the value 1 and it just dormants at other  $\lambda_j$ , 0 at  $\lambda_1$ , 0 at  $\lambda_2$ , 0 at  $\lambda_j - 1$ . The moment it hits  $\lambda_j$ , it peaks up to 1 and again at  $\lambda_j + 1$  goes to 0, and  $\lambda_j + 2$ , it is 0 and  $\lambda_k$ , it is 0. So,  $l_j(\lambda_r)$  is equal to 1, if  $r$  equal to  $j$ , 0, if  $r$  not equal to  $j$ . So, we have polynomials  $l_j(\lambda)$  equal to 1, 2,  $k$ . So, we have got  $k$  polynomials, which are such that each polynomial lights up at one particular eigen value and dice of at other eigen value.

poly convert

$$l_1(\lambda) = \frac{(\lambda-2)(\lambda-(-2))}{(4-2)(4-(-2))} = \frac{(\lambda-2)(\lambda+2)}{2 \times 6} = \frac{\lambda^2-4}{12}$$

$$l_2(\lambda) = \frac{(\lambda-4)(\lambda-(-2))}{(2-4)(2-(-2))} = \frac{(\lambda-4)(\lambda+2)}{-8} = \frac{\lambda^2-2\lambda-8}{-8}$$

$l_1$  takes the value 1 at  $\lambda = 4$  and 0 at all the other  $\lambda$ 's.  $l_2$  takes the value 1 at  $\lambda = 2$  and 0 at all the other  $\lambda$ 's. So, if you just loosely plot, assuming that, suppose  $\lambda_1, \lambda_2$  and  $\lambda_k$  were all real numbers and if we are plotting this  $l_j$ , so let us say we are going to plot  $l_j$  along the  $y$  axis and this is the  $\lambda$  axis. Then,  $l_j$  will take the value 0 here, 0 here and it will be 0 here, except at  $\lambda_j$ , it will take the value 1. So, that is what we mean, when we say that this lights up at  $\lambda_j$  and 0 at all other places. It looks like  $\lambda_j$  is a switch for the polynomial  $l_j$ .

So, we have these polynomials, these  $k$  polynomials  $l_1(\lambda), l_2(\lambda)$  and  $l_k(\lambda)$  are called the Lagrange interpolation polynomials. Corresponding to the points,  $\lambda_1, \lambda_2$  and  $\lambda_k$ , these are the distinct points corresponding to  $\lambda_1, \lambda_2$  and  $\lambda_k$ . So, we have this  $k$  Lagrange interpolation polynomial. Let us look at some examples. Let us look at the matrix again,  $\begin{bmatrix} 1 & -3 & 3 \\ 2 & 0 & 2 \\ 1 & 3 & -1 \end{bmatrix}$ . Again, this is the same matrix, which we have seen at the beginning of the class, as well as the previous lectures. We have found that the characteristic polynomial is  $(\lambda - 4)(\lambda - 2)(\lambda + 2)$ . Now, what are the eigen values? The distinct eigen values are  $\lambda_1 = 4, \lambda_2 = 2,$  and  $\lambda_3 = -2$ . Now, let us construct the Lagrange interpolation polynomials corresponding to these  $\lambda_1, \lambda_2$  and  $\lambda_3$ . How do I construct the first polynomial?

Lecture31.jnt - Windows Journal

Lagrange Poly:

$$l_1(\lambda) = \frac{(\lambda-2)}{(4-2)} = \frac{\lambda-2}{2}$$
$$l_2(\lambda) = \frac{(\lambda-4)}{(2-4)} = -\frac{\lambda-4}{2}$$

The first polynomial is constructed by writing the terms, lambda minus lambda minus and we put the value, except the first eigen value. So, lambda minus 2 into lambda minus minus 2 and then, divide it by evaluating the numerator at the first eigen value. So, it will be 4 minus 2 into 4 minus minus 2, which is lambda minus 2 into lambda plus 2 divided by 2 into 6, which is lambda squared minus 4 by 12. That is the first lagrange polynomial.

The second langrange polynomial is, again you write lambda minus lambda minus and then, you skip the second eigen value and put the remaining two eigen values. Then, in the denominator, write the numerator with the lambda replaced by the second eigen value now. Second eigen value is 2. So, it is 2 minus 4 into 2 minus minus 2, which is lambda minus 4 into lambda minus 2 divided by minus 8, which can be written as lambda squared, this plus 2, lambda squared minus 2 lambda minus 8 by minus 8.

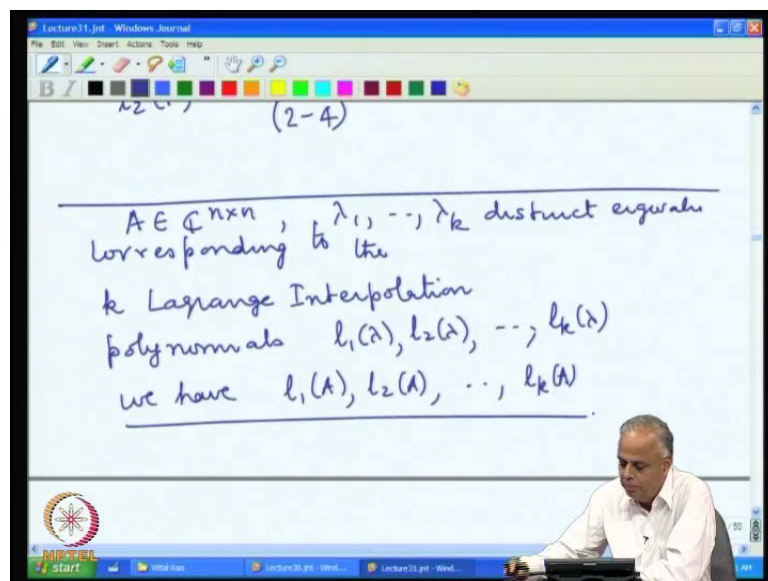

The third lagrange interpolation polynomial is, again you write lambda minus and lambda minus and skip the third eigen value. So, you put the first one, 4 and 2 and then, in the denominator, replace the lambda by the third eigen value, which is minus 2, which is equal to lambda squared minus 6 lambda plus 8 divided by minus 6 into plus 4 minus 6 into minus 4, which is 24. So, whatever is the simplification. So, we have got these three lagrange interpolation polynomials. Let us look at another example. a is 3 minus 1 1 and then, minus 1 1 1 and 0 0 4. This is another example, which we have seen in the

previous lecture. We found that the characteristic polynomial is  $\lambda - 4$ . The quantity squared into  $\lambda - 2$ . Therefore, eigen values were  $\lambda_1 = 4$  and  $\lambda_2 = 2$ . There are only two distinct eigen values now.

The eigen value 4 repeats twice. So, the distinct eigen values are 4 and 2. So, now, the construction of the lagrange polynomials is much easier now. The lagrange polynomials are, now since there are two distinct eigen values, there are going to be two lagrange interpolation polynomials. How do I get the first one? Now, I have only, out of two, I have to remove one of them. So, I get  $\lambda - 2$ , I should not take the first eigen value. I should take the second one. That divided by, in the denominator you replace  $\lambda$  by the first eigen value, which is  $\lambda - 4$ .

To get the second one, skip the second eigen value and write only the factor involved in first eigen value. In the denominator, replace  $\lambda$  by the second eigen value we get  $\lambda - 4$ . So, these are the only two lagrange interpolation polynomials for this matrix, because only there are two distinct eigen values. So now, we are seeing that given any  $k$  distinct numbers,  $\lambda_1, \lambda_2, \dots, \lambda_k$ , in particular given the  $k$  distinct eigen value of the matrix  $A$ , with these we associate the  $k$  lagrange interpolation polynomials  $l_1, l_2, \dots, l_k$ .

(Refer Slide Time: 32:50)

This special properties of these lagrange interpolation polynomials is, the  $j$  th polynomial vanishes except at the  $j$  th eigen value, At the  $j$  th eigen value, it takes the value 1. So,  $l_j$

$\lambda_j$  is 1,  $l_j \lambda_r$  is 0, if  $r$  is not equal to  $j$ . This is the special property of the Lagrange interpolation polynomials. Now, let us see, how we will use these Lagrange interpolation polynomials. Now suppose, we have these polynomials corresponding to the matrix  $A$ . We have seen that, corresponding to every polynomial in  $\lambda$ , we have the corresponding polynomial matrix  $l_j \lambda$ . So therefore, corresponding to, let us take a general matrix  $A \in \mathbb{C}^{n \times n}$  and then,  $\lambda_1, \lambda_2, \dots, \lambda_k$  distinct eigen values. Now, once I have distinct eigen values  $k$  of them, we have  $k$  Lagrange interpolation polynomials. Corresponding to the  $k$  Lagrange interpolation polynomials, what are they?  $l_1 \lambda, l_2 \lambda, \dots, l_k \lambda$ .

A screenshot of a lecture slide from a Windows Journal application. The slide contains handwritten text and equations in black ink on a white background. The text reads: "is any poly,", followed by "then", and then the polynomial equation  $p(\lambda) = a_0 + a_1 \lambda + \dots + a_n \lambda^n$ . Below this, the matrix polynomial is defined as  $p(A) = a_0 I + a_1 A + a_2 A^2 + \dots + a_n A^n$ . The next line shows the application of the polynomial to a vector  $u$ :  $\Rightarrow p(A)u = (a_0 I + a_1 A + a_2 A^2 + \dots + a_n A^n)u$ . This is then expanded to  $= a_0 u + a_1 (\lambda_j u) + a_2 (\lambda_j^2 u) + \dots + a_n \lambda_j^n u$ , and finally simplified to  $= (a_0 + a_1 \lambda_j + a_2 \lambda_j^2 + \dots + a_n \lambda_j^n) u$ . In the bottom right corner, a small inset shows a man in a white shirt looking at a laptop. The bottom of the slide features the NPTEL logo and a Windows taskbar with several open windows.

(Refer Slide Time: 37:45)

We have the corresponding matrices,  $1 \ 1 \ a$ ,  $1 \ 2 \ a$  etcetera and  $1 \ k \ a$ . We will see these matrices. Now, suppose  $u$  is an eigen vector, corresponding to eigen value  $\lambda_j$ . What does this mean? This means, since it is an eigen vector, that is,  $Au = \lambda_j u$  and  $u$  is not equal to  $\theta n$ . So,  $Au = \lambda_j u$ , that is the eigen equation. Since it is an eigen vector, it must be non zero. If that is the case, we get, multiplying both sides by  $A$ , we get  $A^2 u = \lambda_j^2 u$ , that is  $A^2 u = \lambda_j^2 u$ . But,  $Au = \lambda_j u$ . So,  $A^2 u = \lambda_j^2 u$ . So,  $A^3 u = \lambda_j^3 u$  and similarly, recursively, we get, for any power  $r$ ,  $A^r u = \lambda_j^r u$ , for every non negative integer.  $A^5 u$  will be  $\lambda_j^5 u$ ,  $A^{25} u$  will be  $\lambda_j^{25} u$  and so on.

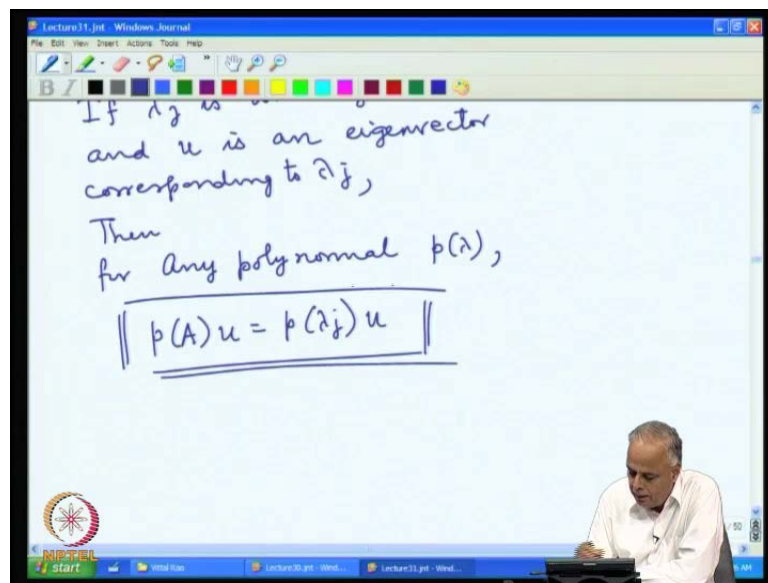

In general,  $A^r u$  will be equal to  $\lambda_j^r u$ . So, therefore, if  $u$  is an eigen vector, then to calculate the power of the matrix  $A$  acting on  $u$ , all we have to do is take the power of the eigen value and multiply it with the vector. Now, this has an additional simplification. Suppose, now  $p(\lambda)$  is equal to  $a_0 + a_1 \lambda + a_2 \lambda^2 + \dots + a_r \lambda^r$ , is any polynomial with complex coefficient, any polynomial, then we know,  $p(A)u = a_0 u + a_1 Au + a_2 A^2 u + \dots + a_r A^r u$ . This is how it is defined,  $p(A)$  corresponding to any polynomial  $p(\lambda)$ . Therefore, what is  $p(A)u$ ?  $p(A)u = a_0 u + a_1 \lambda_j u + a_2 \lambda_j^2 u + \dots + a_r \lambda_j^r u$ . Now, we multiply  $a_0 u$  times  $u$  is  $a_0 u$ , plus  $a_1 \lambda_j u$  is  $\lambda_j a_1 u$

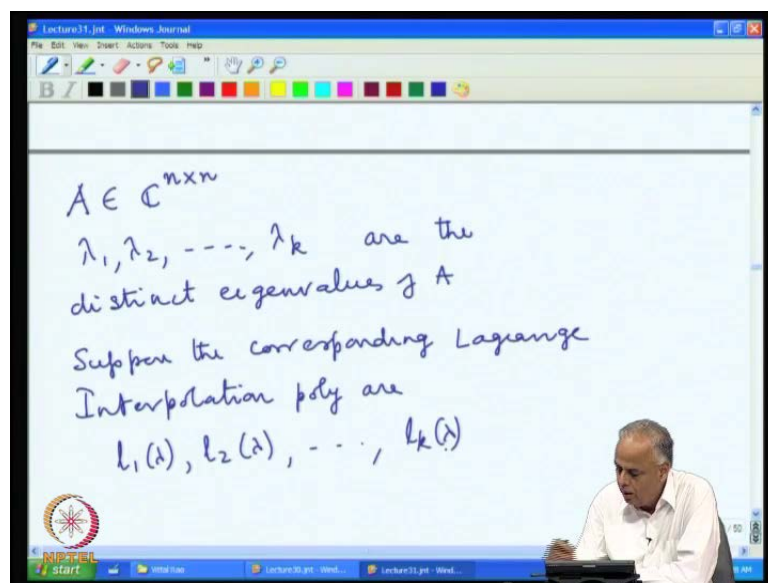

$\lambda_j u$ , because  $u$  is an eigen value.  $\lambda_j^2$ , a squared  $u$  is  $\lambda_j^2 u$ . We have just now seen that and so on,  $\lambda_j^r u$ .

We see that, this can be written as  $1 u + \lambda_j u + \lambda_j^2 u + \dots + \lambda_j^r u$ . What is in bracket? It is nothing, but the polynomial  $p$  evaluated at point  $\lambda_j$ . So,  $p(\lambda_j) u$ . So, what is our conclusion?

(Refer Slide Time: 38:22)

(Refer Slide Time: 39:25)

The conclusion is that, if  $\lambda_j$  is an eigen value of  $A$  and  $u$  is an eigen vector, corresponding to the eigen value  $\lambda_j$ , then for any polynomial  $p(\lambda)$ , we are

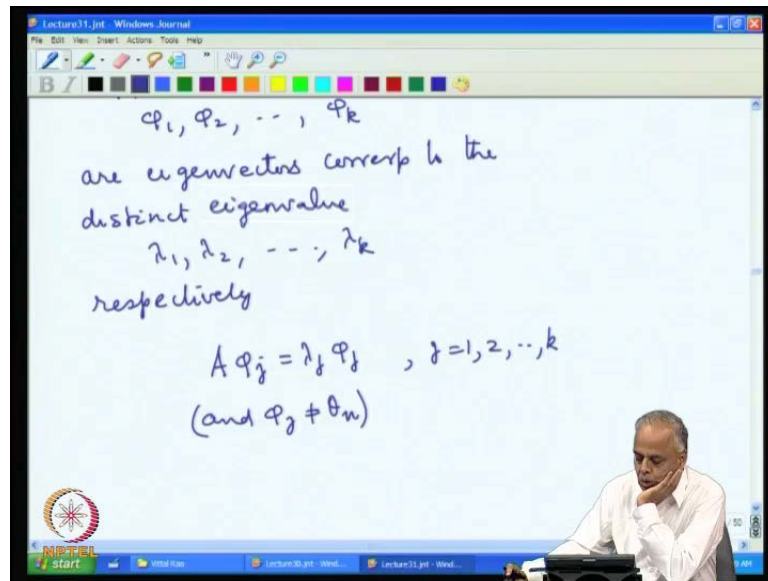

assuming everything over complex, where any polynomial  $p(\lambda)$ ,  $p(A)u$  is equal to  $p(\lambda_j)u$ . This is a very important identity, because it says, the computation over the matrix, calculating the polynomial matrixes action on  $u$  is a very simple action. We have to simply calculate the value of the polynomial at the eigen value and multiply with the vector  $u$ . So, this is a very nice and simple identity regarding eigen values, eigen vectors and polynomials. How do we use this? Therefore, now let us look at a matrix  $A$  and then, say  $\lambda_1, \lambda_2$  and  $\lambda_k$  are the distinct eigen values of  $A$ . Suppose, the corresponding, the moment we have the eigen values, distinct eigen values, we have seen, we can construct the corresponding lagrange interpolation polynomial.

(Refer Slide Time: 40:24)

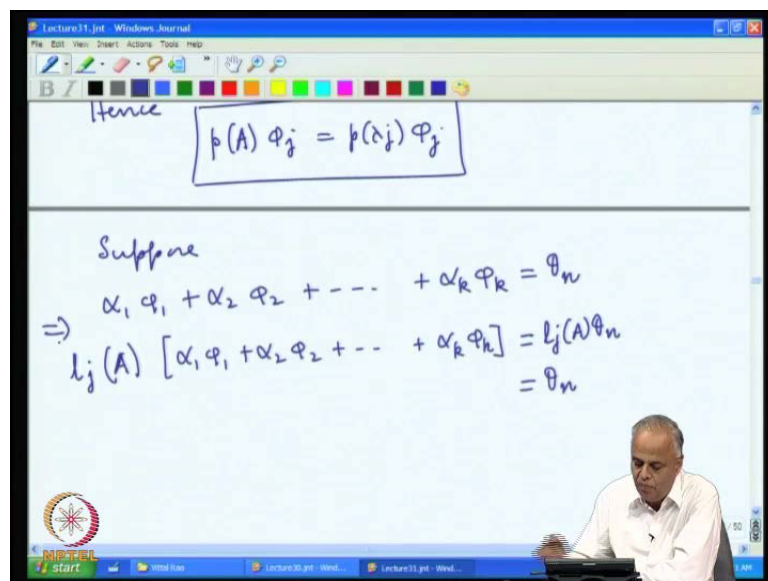

$$l_j(\lambda) = \begin{cases} 0 & \text{if } \lambda \neq \lambda_j \\ 1 & \text{if } \lambda = \lambda_j \end{cases}$$

Suppose  $\phi_1, \phi_2, \dots, \phi_k$

(Refer Slide Time: 41:16)

(Refer Slide Time: 42:04)

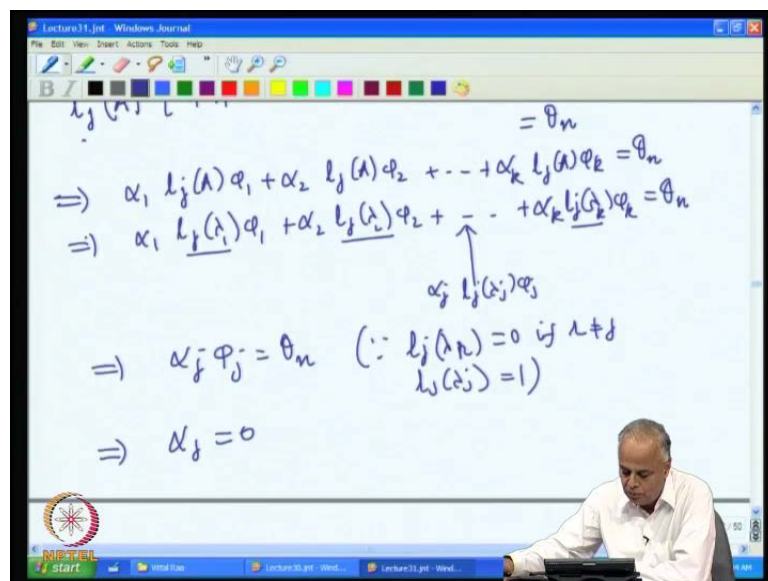

So, the corresponding lagrange interpolation polynomials are  $l_1(\lambda)$ ,  $l_2(\lambda)$  etcetera, and  $l_k(\lambda)$ . Then, what do we know about them. Remember,  $l_j(\lambda_r)$  is 0, if  $r$  is not equal to  $j$  and equal to 1, if  $r$  equal to  $j$ . This is the characteristic property of the lagrange interpolation polynomial. The  $j$  th polynomial lights up at the  $j$  th eigen value. Now, we have these  $k$  distinct eigen values. Suppose,  $\varphi_1$ ,  $\varphi_2$  and  $\varphi_k$  are eigen vectors corresponding to these distinct eigen values  $\lambda_1$ ,  $\lambda_2$  and  $\lambda_k$  respectively. So,  $\varphi_1$  is the eigen vector corresponding to  $\lambda_1$ ,  $\varphi_2$  is the eigen vector corresponding to the  $\lambda_2$  and so on. So, what does that mean? a  $\varphi$

$\phi_j$  is equal to  $\lambda_j \phi_j$  for  $j = 1, 2, \dots, k$  and the  $\phi_j \neq 0$ . They are non zero vectors because, they are present to be eigen vectors.

So, we have  $\phi_j$  equal to  $\lambda_j \phi_j$  and we have just now observed that, when we have an eigen vector, the polynomial evaluation is easy. Hence from our above calculation,  $p(\lambda_j) \phi_j$  is equal to  $p(\lambda_j) \phi_j$ . This is what we have calculated and found about that the polynomial matrix evaluation acting on the eigen vector is polynomial evaluation, the eigen value multiplying the eigen. Now, how we are going to use? Now, we're claiming that the eigen vectors corresponding to distinct eigen values are linearly independent. So, what we were claiming is, over that  $\phi_1, \phi_2$  and  $\phi_k$  must be linearly independent. So, let us see how we get it. How do we prove that  $\phi_1, \phi_2, \dots, \phi_k$  are linearly independent. We have to show that, if any linearly combination is 0, then coefficients must be 0.

(Refer Slide Time: 44:04)

So, we start with linear combinations. Suppose  $\alpha_1 \phi_1 + \alpha_2 \phi_2 + \dots + \alpha_k \phi_k = \theta_n$ . We want to show that  $\alpha_1$  must be 0,  $\alpha_2$  must be 0 and  $\alpha_k$  must be 0. That will establish linear independence. Now, what we do is, we multiply both sides by the matrix  $l_j(\lambda)$ , where  $l_j$  is the  $j$ th Lagrange interpolation polynomial. Now, that will be  $l_j(\lambda) \theta_n$ . But any matrix multiplying 0 vectors gives the 0 vector. So, if  $\alpha_1 \phi_1 + \alpha_2 \phi_2 + \dots + \alpha_k \phi_k = \theta_n$ , then  $l_j(\lambda) \theta_n$  must be zero 0.

That says,  $\alpha_1 \phi_1 + \alpha_2 \phi_2 + \dots + \alpha_k \phi_k = 0$ . Now,  $\phi_1$  is an eigen vector and  $\phi_1$  is an eigen vector corresponding to  $\lambda_1$ . We have seen from this fact that for any polynomial  $p$   $\phi_1$  will be  $p(\lambda_1) \phi_1$ . So,  $\phi_1$  will be  $\lambda_1 \phi_1$ . So, this will be  $\lambda_1 \phi_1$ , and  $\lambda_2 \phi_2$  and so on. Then, there will be an  $\alpha_k$  and  $\lambda_1 \lambda_2 \dots \lambda_k$  must be 0. Now, what is the property of these  $\lambda_j$ 's? The  $\lambda_j$ 's are such that, they light up only at  $\lambda_j$  and at  $\lambda_1, \lambda_2, \dots, \lambda_k$  that takes the value 0.

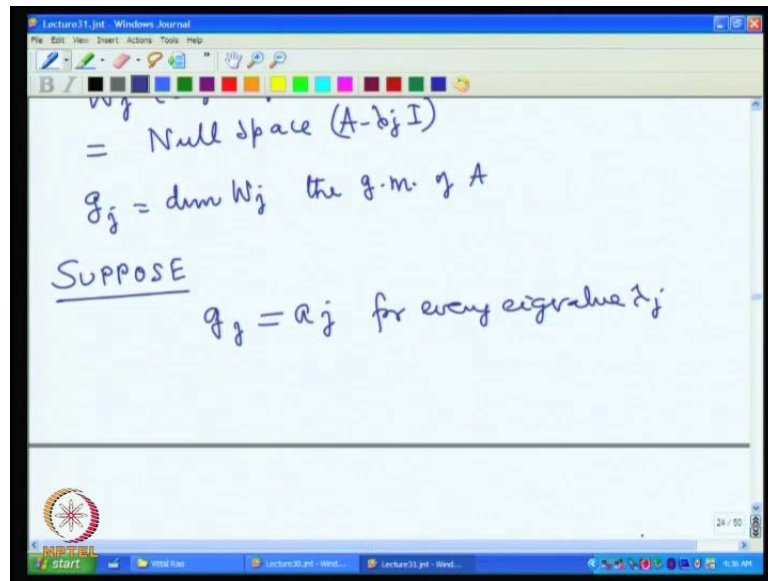

(Refer Slide Time: 46:34)

$\Rightarrow \alpha_j = 0$  for each  $j = 1, 2, \dots, k$   
 $\Rightarrow \phi_1, \phi_2, \dots, \phi_k$  l.i.  
Conclusion:  
 Eigenvectors corresponding to distinct eigenvalues are l.i.

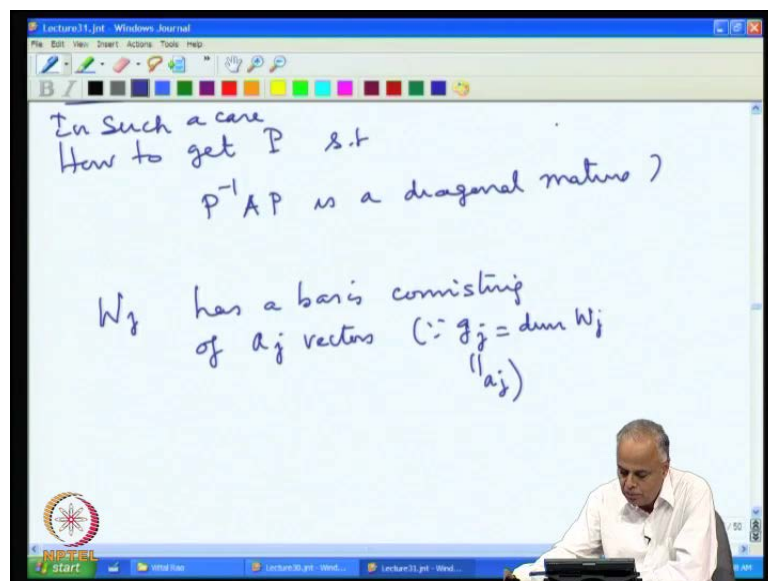

(Refer Slide Time: 47:38)

$C_A(\lambda) = (\lambda - \lambda_1)^{a_1} \dots (\lambda - \lambda_k)^{a_k}$   
 $\lambda_1, \dots, \lambda_k$  distinct eigenvalues  
 $a_1, \dots, a_k$  their algebraic mult.  
 $W_j$  (eigenspace corr. to  $\lambda_j$ )  
 $=$  Null space  $(A - \lambda_j I)$

(Refer Slide Time: 48:34)

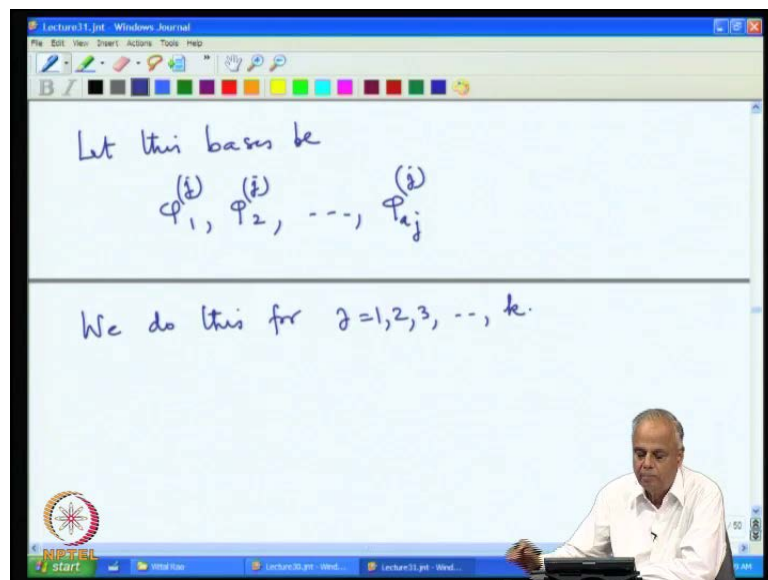

(Refer Slide Time: 49:20)

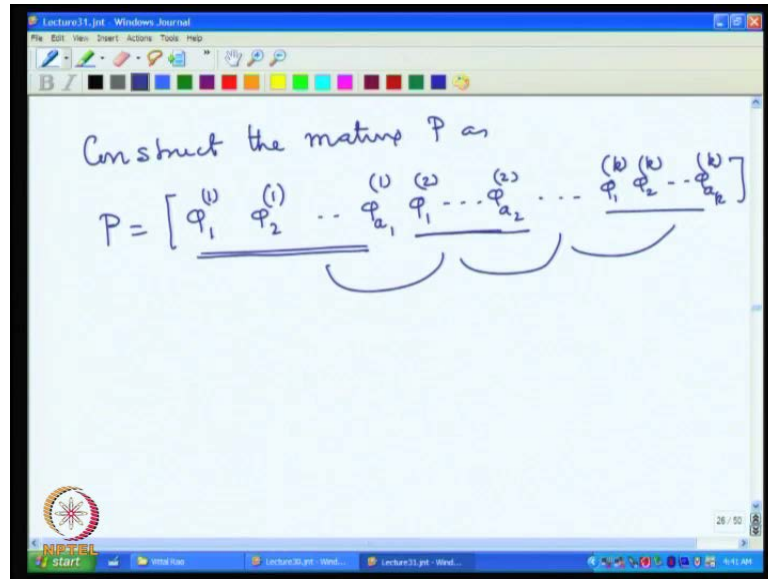

So therefore,  $1_j \lambda_j$  will be 0, 1 and  $1_j \lambda_j$  will be 0. The only term that will survive will be  $1_j \lambda_j$ . That term, because  $1_j \lambda_j$  is 1 and this will become simply  $\alpha_j \phi_j = \theta_n$ . Because,  $1_j \lambda_j = 0$ , if  $r \neq j$ , and  $1_j \lambda_j = 1$ . If use those, you get this. But now,  $\phi_j$  was an eigen vector. Therefore,  $\phi_j$  was a non zero vector. So, since  $\phi_j$  is a non zero vector,  $\alpha_j \phi_j = \theta_n$  implies  $\alpha_j = 0$ . This we can do for every  $j$ . If we start with 1 1, we get  $\alpha_1 = 0$ . If we start with 1 2 here, we get  $\alpha_2 = 0$ . So therefore, each  $j$  equal to 1, 2 till  $k$ . So, that says  $\phi_1, \phi_2$  and  $\phi_k$  are linearly independent.

This is the result that we said in last lecture that we will prove later. So, the conclusion is that, eigen vector corresponding to distinct eigen values are linearly independent. So, this completes our argument that we started in the last lecture about matrixes, for which algebraic multiplicity was equal to geometric multiplicity. So, in summary, we have the following result. Namely, suppose I have a matrix  $a$ , which belong to the complex  $n$  by  $n$  and its characteristic polynomial is  $(\lambda - \lambda_1)^{a_1} (\lambda - \lambda_2)^{a_2} \dots (\lambda - \lambda_k)^{a_k}$ .  $\lambda_1, \lambda_2, \dots, \lambda_k$  distinct eigen values and  $a_1, a_2, \dots, a_k$  their algebraic multiplicity. So, we have these eigen values and eigen multiplicity. Then,  $w_j$ , the eigen space corresponding to  $\lambda_j$ , which is equal to null space of  $a - \lambda_j I$ . Then, we have  $g_j$  equal to dimension of  $w_j$ , the geometric multiplicity of  $a$ . Suppose,  $g_j$  equal to  $a_j$  for every eigen value  $\lambda_j$ . So we have, if the matrix  $a$  is such that the algebraic multiplicity is equal to the geometric multiplicity for every eigen value, then  $a$  is diagonalizable. So, how do we? Then, how to get  $p$ , such that  $p^{-1} a p$  is a diagonal matrix. In such a case, how do we get the  $p$  matrix, that  $p^{-1} a p$  is diagonal matrix.

(Refer Slide Time: 51:15)

(Refer Slide Time: 51:34)

What we do if the following, we look at  $w_j$  has a basis, null space, the sub space, the basis, now its dimensions in the geometric multiplicity because the geometric multiplicity is algebraic multiplicity which dimension is a  $j$ . Since, its dimensions is a  $j$ , a basis will consist of a  $j$  vectors, because  $g_j$  equal to  $a_j$  and  $g_j$  is equal to  $a_j$ . This is what we are assuming. We are assuming that suppose the geometric multiplicity is equal to algebraic multiplicity. So, it has a basis consisting of a  $j$  vectors. Let this basis be. So, we always find the null space of, first we find an eigen value and then we find then null space.

Then, we find the basis for the null space. Let this basis be  $\phi_{j1}, \phi_{j2}$  and  $\phi_{ja}$ . This we can do for  $j$  equal to 1, for the eigen value  $\lambda_1$ ,  $j$  equal to 2, the eigen value  $\lambda_2$  and so on. So, we do this for  $j$  equal to 1, 2, 3 up to  $k$ . Then, construct the matrix  $p$  as  $p$  equal to, first you write all the eigen vectors corresponding to the eigen value 1. How many of them are there?  $a_1$  of them are there. Construct, write down all the eigen vectors as columns of this matrix  $p$ . First look at the eigen vectors corresponding to  $\lambda_1$ . They come as the basis of  $w_1$ .

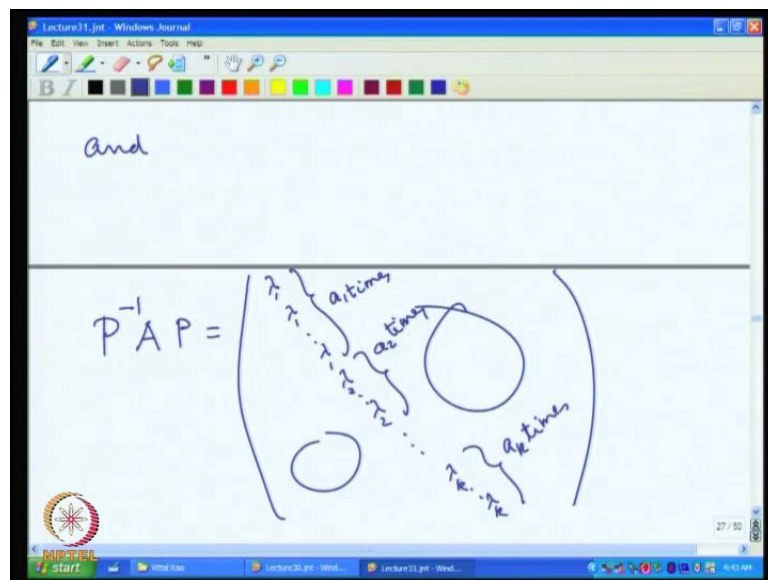

$w_1$  is the basis consisting of a 1 vectors. Take this a 1 basis vectors and put them as the first a 1 columns of  $p$ . This decides the a 1 columns of  $p$ . We need totally  $n$  columns. Then, we write the next a 2 columns, which corresponds to the matrix eigen value  $\lambda_2$ . We continue this process and the last a  $k$  columns will be corresponding to the

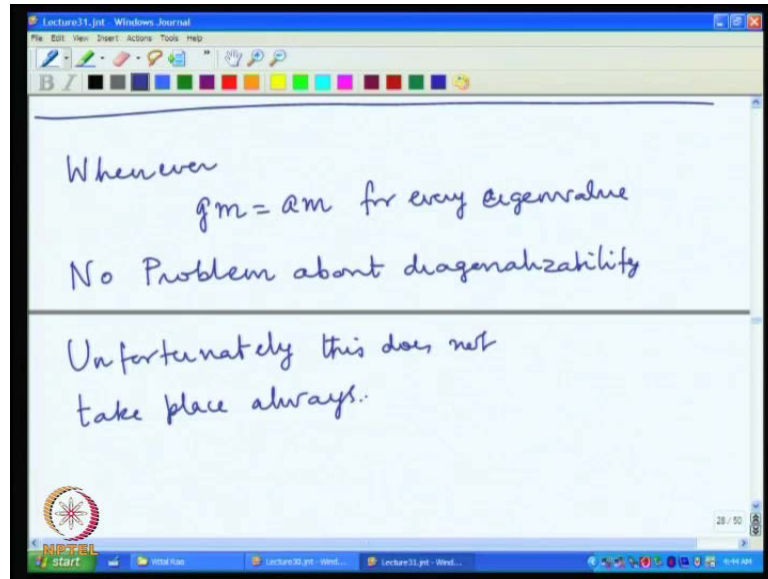

eigen value  $\lambda_k$ . So, we will have a 1 plus a 2 plus a k columns, but a 1 plus a 2 plus a k is equal to n. Therefore, we have n columns, since all the n columns are linearly independent now, by the theorem that we have just proved. These are all linearly independent and these are all linearly independent and these are all linearly independent.

But, across their linearly independent because, we have just now observed that the eigen vectors corresponding to distinct eigen values are linearly independent. So, p is the matrix, n columns, each column is an eigen vector corresponding to  $\lambda$ . The first a 1 columns correspond to the  $\lambda_1$  eigen vectors are the  $\lambda_1$  basis corresponding to  $w_1$ . The next a 2 columns correspond to  $\lambda_2$  eigen vectors corresponding to eigen value  $\lambda_2$  are same as the  $\lambda_2$  basis vectors for  $w_2$ .

(Refer Slide Time: 54:40)

(Refer Slide Time: 56:08)

Continuing this process, the last  $a_k$  columns are the  $a_k$  eigen vectors corresponding to the eigen value  $\lambda_k$  are same as the  $a_k$  basis vectors corresponding to the sub space  $w_k$ . The eigen space  $w_k$ . Then, all the columns are linearly independent,  $p$  is invertible. Since, columns are linearly independent and when we write  $p$  inverse a  $p$ , we get a diagonal matrix. What is the diagonal matrix? The diagonal entries are going to be,  $\lambda_1$  will appear along the diagonal  $a_1$  times, then  $\lambda_2$  will appear  $a_2$  times and so on. In the end,  $\lambda_k$  will appear  $a_k$  times.

So, this will be huge diagonal matrix and  $n$  by  $n$   $\lambda_1$  will appear  $a_1$  times and  $\lambda_2$   $a_2$  times along the diagonal. Finally,  $\lambda_k$   $a_k$  times, and  $a$  becomes diagonalizable. In case, all the eigen values with the matrix  $a$  is real and all the eigen values are real, then  $p$  can also be chosen as real, if  $j$   $g_m$  equal to  $a_m$ . So, thus we know that, if the geometric multiplicity is equal to the algebraic multiplicity for every eigen value, the diagonalization problems can be completely resolved. But the moment we have shortage of eigen vectors, that is if geometric multiplicity becomes smaller than the algebraic multiplicity, we have problems. So, whenever  $g_m$  is equal to  $a_m$  for every eigen value, so this is the main moral of our discussion.

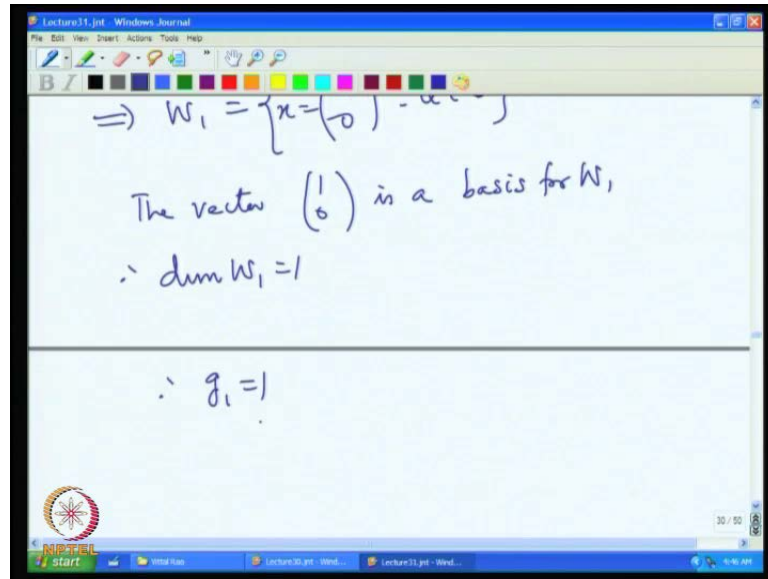

(Refer Slide Time: 57:07)

$$A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$$
$$C_A(\lambda) = \det(\lambda I - A) = \begin{vmatrix} \lambda & -1 \\ 0 & \lambda \end{vmatrix} = \lambda^2$$
$$\lambda_1 = 0 \quad a_1 = 2$$

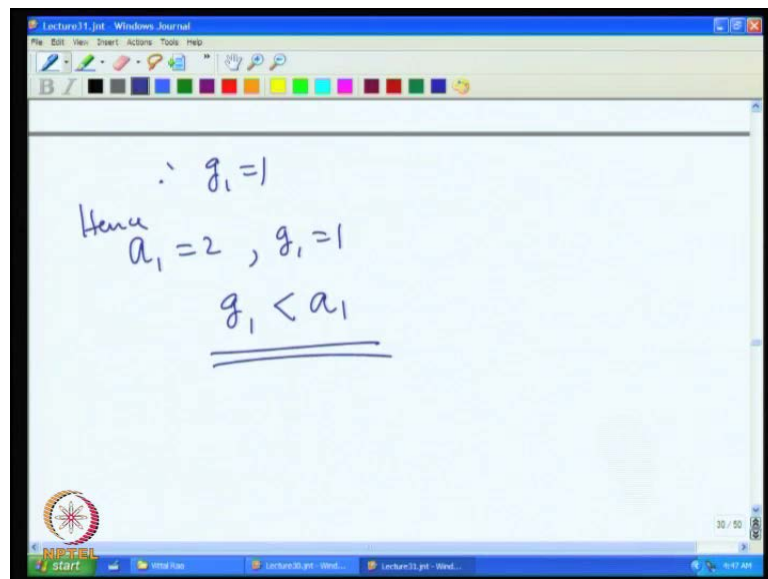

(Refer Slide Time: 57:40)

$$W_1 = \text{Null sp}(A - \lambda_1 I)$$
$$= \text{Null sp } A$$
$$A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$$
$$Ax = 0_2 \Rightarrow x_2 = 0$$
$$\Rightarrow W_1 = \left\{ x = \begin{pmatrix} \alpha \\ 0 \end{pmatrix} : \alpha \in \mathbb{C} \right\}$$

(Refer Slide Time: 58:25)

(Refer Slide Time: 58:42)

Whenever  $g_m$  is equal to  $a_m$  for every eigen value, no problem about diagonalizability. But unfortunately, it is not always the case. Unfortunately, this does not take place always. That is, there are matrices for which  $g_m$  will not be equal to  $n$ . For example, let us look at a simple example. Consider the matrix  $A$  equal to  $\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$ , then the characteristic polynomial which is the determinant of  $\lambda I - A$ , which is the determinant  $\lambda^2 - 1$ , which is  $(\lambda - 1)^2$ . We have seen this before again.

So, there is only one eigen value 0, with algebraic multiplicity as 2. So, let us find the eigen space. We have to find the null space of  $A - \lambda I$ .  $\lambda$  is 0, which is the same thing as null space of  $A$ . But,  $A$  is the matrix  $\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$ . So, to find the null space, we must solve this equation  $Ax = 0$ , which gives us  $x_2 = 0$ . That is the only equation. Therefore,  $W_1$  consist of all vectors for which  $x_2$  is 0 and  $x_1$  can be anything. The vector  $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$  is a basis for  $W_1$ . Therefore, dimension of  $W_1$  is 1 and therefore,  $g_1$  is equal to 1. So, in this case, we have  $a_1$  equal to 2,  $g_1$  equal to 1 and we have  $g_1$  strictly less than  $a_1$ . So, therefore, there are situations where geometric multiplicity is less than algebraic multiplicity.

Therefore, we look at a class of matrices, for which this is always a guarantee. That is, we would like to have a class of matrix, where by looking at them, we can immediately say these matrices are not going to create any problem. For all these matrices, the geometric multiplicity will be equal to the algebraic multiplicity. These are the so called hermitian matrices, the complex case and the real symmetric matrix is the real case. We shall start looking at them in the next lecture.
