**Hermitian and Symmetric Matrices – Part 4**

(Refer Slide Time: 00:33)

We have been looking at the decomposition of a Hermitian matrix or the sum of rank one matrix; let us recall some of the things that we obtained in this context. So, we shall consider a matrix  $A$ , which is  $H_n$ , that is,  $A$  is Hermitian, we want to express this or the sum of rank one matrices.

Now, we will follow the notation. Let us recall, if  $u$  and  $v$  are in  $C^n$ , and then we define  $v$  tensor  $u$  to be matrix  $uv^*$ , notice that this is an  $n$  by  $n$  matrix; this is an  $n$  by  $n$  matrix. And if we now look at this matrix and look at its Hermitian conjugate, it is  $uv^*$  star star, which is  $v^*^* u^*$ . So, when you take transpose of the product, the product of the transpose in the reverse order. But when you take the Hermitian conjugate of a product, the product comes in reverse order, but  $v^*^*$  is  $v$ , so it is  $vu^*$ . So, we have this notation, that  $v$  cross  $u$  is equal to  $uv^*^*$ , which is  $v^*^* u^*$  is equal to  $vu^*$ .

(Refer Slide Time: 02:23)

$u \otimes u = uu^*$   
 $(u \otimes u)^* = uu^* = u \otimes u$

$u \otimes u$  is in  $H_n$  (i.e. a Hermitian matrix for every  $u \in \mathbb{C}^n$ )

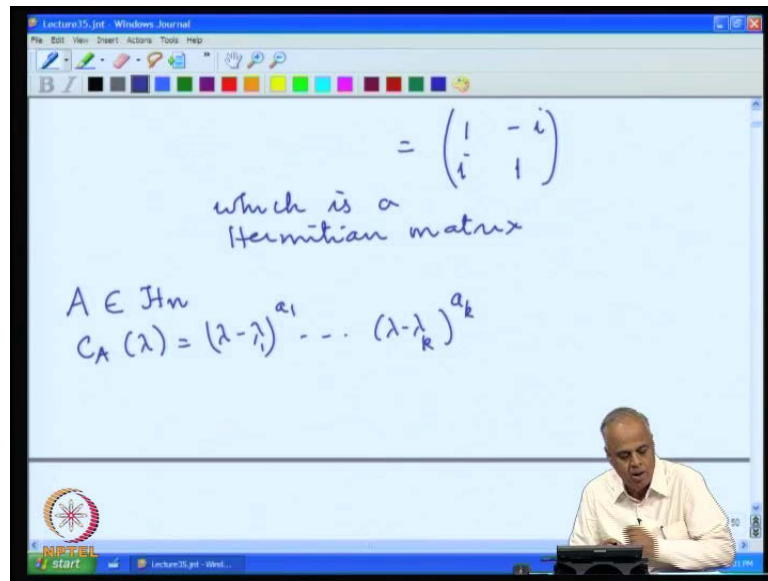

---

For example if  
 $u = \begin{pmatrix} 1 \\ i \end{pmatrix}$   
 $u \otimes u = uu^* = \begin{pmatrix} 1 \\ i \end{pmatrix} \begin{pmatrix} 1 & -i \end{pmatrix}$

Now, we have this tensor notation. With this notation we shall particularly look at the idea of taking the tensor product of a vector with itself. Then, we get  $u$  cross  $u$  as  $uu^*$ , and then  $uu^*$ . Since  $u$  is equal to  $v$  above is equal to  $uu^*$ , which is  $u$  tensor  $u$  and therefore,  $u$  tensor  $u$  is a Hermitian matrix.  $u$  tensor  $u$  is in  $H_n$ , it is a Hermitian matrix; it is a Hermitian matrix for every  $u$  in  $\mathbb{C}^n$ .

For example, if  $u$  equal to say,  $1, i$ , then  $u$  tensor  $u$  is equal to  $uu^*$ ;  $u$  is  $1, i$ ;  $u^*$  is the transpose conjugate, so it is  $1$  minus  $i$ . So, when you take the product to get  $1$  minus  $i, i$  and minus  $i$  square, which is  $1$  and which is Hermitian matrix, which is a Hermitian matrix. So, if you take a vector in  $\mathbb{C}^n$  and take the tensor product of the vector with itself, we get a Hermitian matrix. Now, we use this notation in the decomposition of the matrix.

(Refer Slide Time: 04:09)

The screenshot shows a digital whiteboard with the following handwritten text:

$$= \begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix}$$

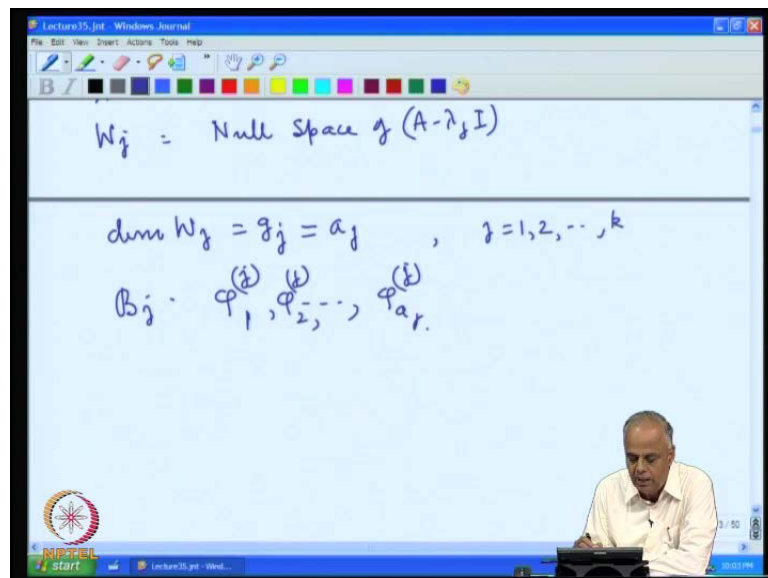

which is a Hermitian matrix

$$A \in \mathcal{H}_n$$
$$C_A(\lambda) = (\lambda - \lambda_1)^{a_1} \cdots (\lambda - \lambda_k)^{a_k}$$

The slide also features a toolbar at the top, a logo in the bottom left, and a small video inset of a lecturer in the bottom right.

Recall, if  $A$  is a Hermitian matrix and its characteristic polynomial is  $\lambda - \lambda_1$  power  $a_1$ , etcetera,  $\lambda - \lambda_k$  power  $a_k$ . Our usual notations were  $\lambda_1, \lambda_2, \lambda_k$  are the distinct Eigen values of  $A$  and  $a_1, a_2, a_k$  are the algebraic multiplicities.

(Refer Slide Time: 04:37)

The screenshot shows a digital whiteboard with the following handwritten text:

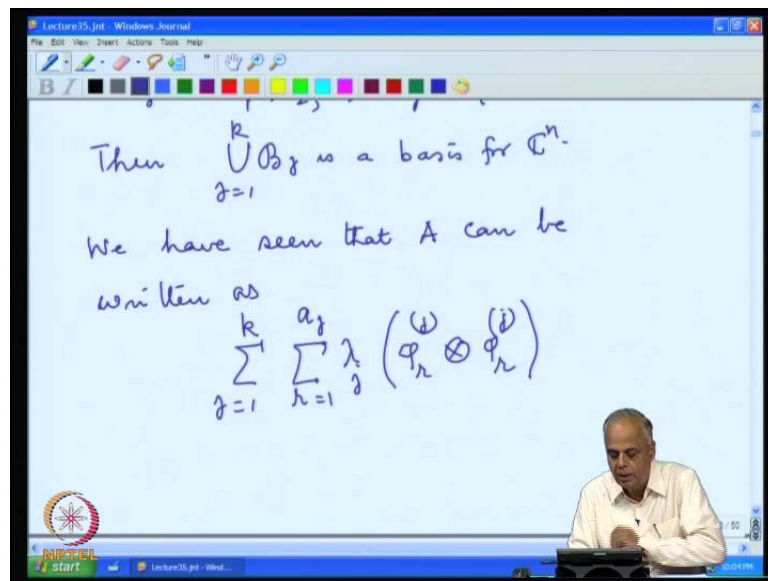

$$W_j = \text{Null Space of } (A - \lambda_j I)$$
$$\dim W_j = g_j = a_j, \quad j = 1, 2, \dots, k$$
$$B_j = \{ \varphi_1^{(j)}, \varphi_2^{(j)}, \dots, \varphi_{a_j}^{(j)} \}$$

The slide also features a toolbar at the top, a logo in the bottom left, and a small video inset of a lecturer in the bottom right.

Then, we have  $W_j$ , the null space of  $A - \lambda_j I$ , which is the eigenspace corresponding to the Eigen value  $\lambda_j$  and the dimension of  $W_j$ , which is the geometric multiplicity, in the case of Hermitian matrix will always be equal to the algebraic multiplicity. This is true for each  $j$  equal 1, 2,  $k$ .

So, for each one of the Eigen values, the corresponding Eigen space has the same dimension as the algebraic multiplicity. Then, we denote it by  $B_j$  and ortho-normal basis for the eigenspace  $W_j$ . The superscript  $j$  says that it is a basis for the eigenspace  $W_j$  and the subscript is the index of the basis vector. This is first basis vector for  $\phi_{j1}$ ,  $\phi_{j2}$  the second basis vector,  $\phi_{ja}$  if the  $a$ , this is vector for  $W_j$ .

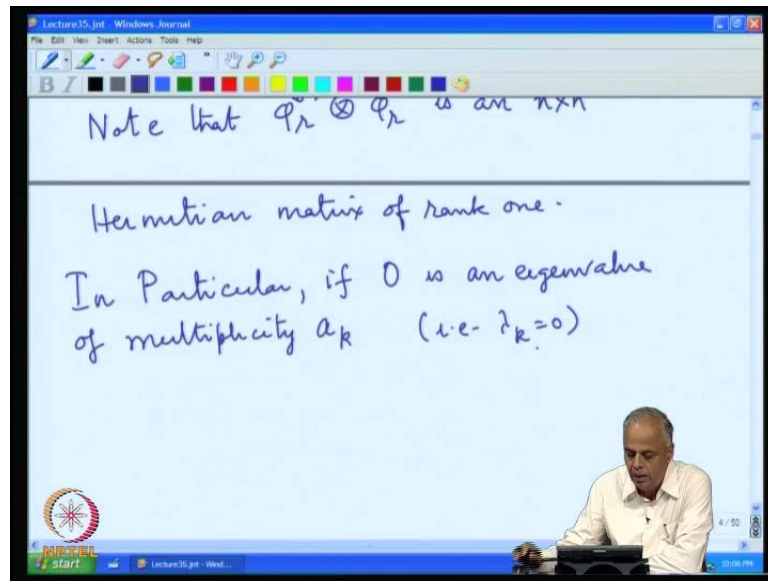

(Refer Slide Time: 05:52)

Then, the union of all this  $j$  equal to 1 to  $k$  is a basis for the whole space. And we saw, that this matrix  $A$ , we have seen, that  $A$  can be written as the following sum. What is that sum? For each one of this Eigen values and eigenspace we look at first the  $B_j$  basis, there are  $a_j$  of them, for each one of these vectors we construct the tensor product.

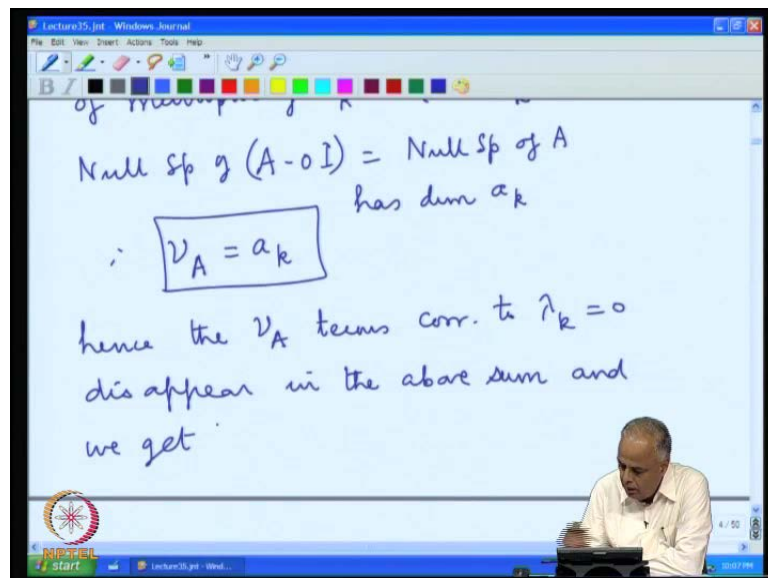

So, we construct  $\phi_{jr}$  tensored with  $\phi_{jr}$  and this is going to be a matrix. As observed above, this is going to be a  $n$  by  $n$  matrix and since it is the tensor product of a tensor with itself, is going to be a Hermitian matrix. And so, that is the Hermitian matrix of order  $n$  by  $n$ , and it is multiplied by the corresponding Eigen values  $\lambda_j$ , and we look at the sum from  $r$  equal to 1, 2,  $a_j$ , that is, for each one of these basis vectors in the  $B_j$  basis or the basis for  $W_j$ , we look at the tensor product. Note, that this is an orthonormal basis, in addition. Now, we do this for every one of the Eigen values, so  $j$  equal to 1 to  $k$ . So, totally, we get a 1 plus a 2 plus a  $k$   $n$  term.

(Refer Slide Time: 07:50)

So, notice, that  $\phi_j \phi_r$ ,  $\phi_j \phi_r$  is a  $n$  by  $n$  Hermitian matrix of rank one. Thus, we have expressed the matrix  $A$  and the sum of matrices of rank one. In particular, if 0 is an Eigen value of multiplicity  $a_k$ , recall  $k$ th Eigen value is leave the 0, then that is, we say  $\lambda_k$  equal to 0.

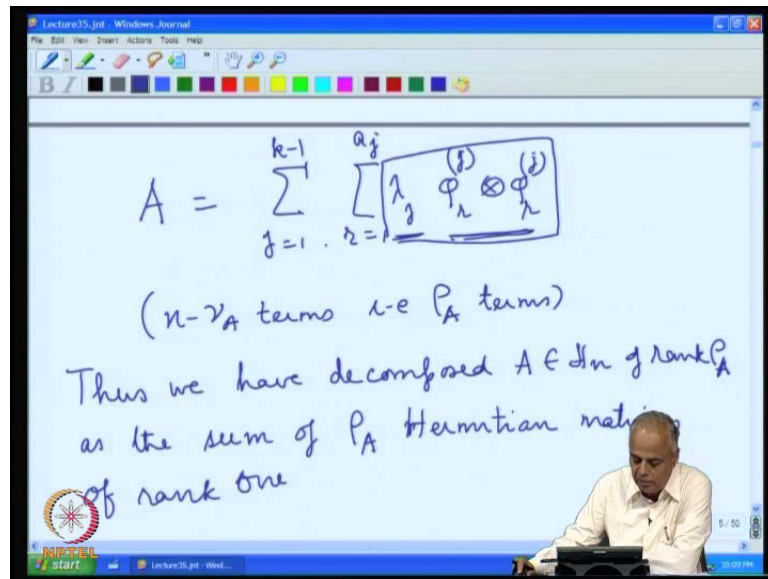

(Refer Slide Time: 08:49)

Then we know, that the null space of  $A$  minus the corresponding Eigen value is 0, so  $A$  minus  $0I$ , which is the same as the null space of  $A$ , must have dimension same as a  $k$ , but we know, that the dimension of the null space of  $A$  is  $\nu_A$ . Therefore, the nullity must be equal to a  $k$ .

So, suppose we have 0 as an Eigen value, then  $\nu_A$  must be equal to the algebraic and geometric multiplicity of this Eigen value. And therefore, if you look at the sum, in the sum corresponding to the term  $\lambda_j$  we will be multiplying by  $\lambda_j$  every one of these  $a_j$  terms, but  $\lambda_j$  being 0, these terms will disappear and hence, the  $\nu_A$  terms corresponding to  $\lambda_j$  equal to 0 disappear in the above sum.

(Refer Slide Time: 10:09)

And we get  $A$  equal to summation  $j$  equal to 1 to  $k$  minus 1, summation  $r$  equal to 1 to  $a_j$   $\lambda_j \phi_j^r$  tensored with  $\phi_j^r$ . Now, obviously there are  $a_1$  plus  $a_2$  plus  $a_{k-1}$ , which is  $n - \nu_A$ , so  $n - \nu_A$  terms, but  $n - \nu_A$  is the rank of the matrix, so  $\rho_A$  terms. So, we have, now each one of them is non-zero, because these are orthonormal vectors, they are non-zero vectors and  $\lambda_j$  are non-zero.

So, thus we have  $A$ , we have decomposed  $A$ , which is a Hermitian matrix, as and its rank is  $\rho_A$ , so its rank is  $\rho_A$  as the sum of  $\rho_A$  matrix. In fact,  $\rho_A$  Hermitian matrices of rank one, each one of these terms is Hermitian. This is real because Hermitian matrices, the Eigen values are real. So, when you multiply a Hermitian matrix by real number you get a Hermitian matrix, so this all quantity is a Hermitian matrix. So, therefore, the whole sum, if the sum of Hermitian matrices and each as rank 1.

So, thus we have seen, that if I have a Hermitian matrix of rank  $\rho$ , it can there be split into the sum of  $\rho$  rank 1 matrices. We will always reduce everything to one rank level. Let us look at some examples of this decomposition.

(Refer Slide Time: 12:12)

(1)  $A = \begin{pmatrix} 6 & -2 & 2 \\ -2 & 3 & -1 \\ 2 & -1 & 3 \end{pmatrix}$

Real Symm matrix  
 $C_A(\lambda) = (\lambda - 2)^2 (\lambda - 8)$

It has two distinct eigenvalues  
 $\lambda_1 = 2$  ;  $a_1 = 2$   
 $\lambda_2 = 8$  ,  $a_2 = 1$ .

The screenshot shows a digital whiteboard with a toolbar at the top and a small inset video of a lecturer in the bottom right corner. The whiteboard contains handwritten mathematical text and a matrix.

So, let us look at the first example, the matrix, which you have seen in the last lecture. You see, that in all the above decompositions, in particular, if  $A$  is real symmetric, we replace star by transpose everywhere because conjugation does not give anything new in the real situation. So, this a real symmetric matrix and we have seen, that in the previous lectures, that its characteristic polynomial is  $\lambda$  minus 2 square into  $\lambda$  minus 8 and therefore, it has, it has two Eigen values. It has two distinct Eigen values, one of them is 2 and its multiplicity is 2 because they have  $\lambda$  minus 2 square. The second Eigen value is 8 and its multiplicity is 1.

(Refer Slide Time: 13:56)

$\lambda_2 = 8$  ,  $a_2 = 1$

0 is not an eigenvalue  
 $\therefore$  Nullity is 0

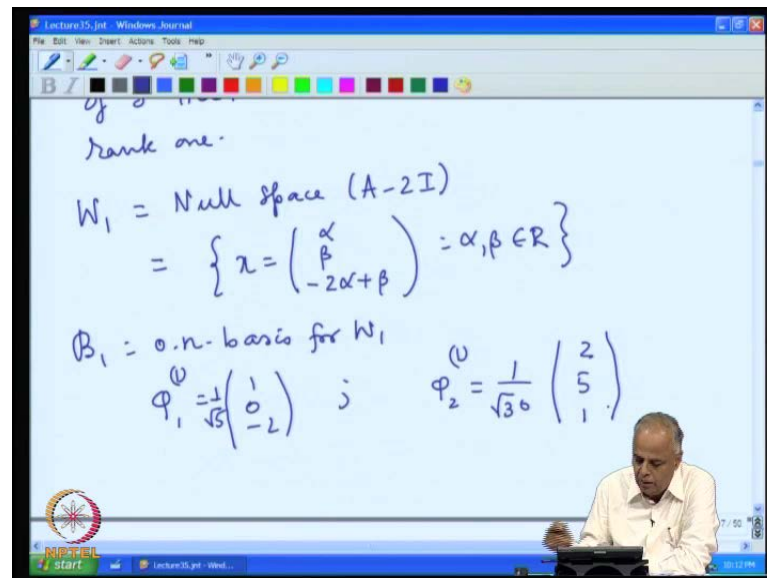

Rank of  $A = 3$

We shall express  $A$  as the sum of 3 Hermitian matrices each of rank one.

The screenshot shows a digital whiteboard with a toolbar at the top and a small inset video of a lecturer in the bottom right corner. The whiteboard contains handwritten mathematical text.

We see therefore, that 0 is not an Eigen value, therefore nullity is 0 and hence, rank is three. Since the rank is 3, we shall express A as the sum of three Hermitian matrices, each of rank one. How do we do this? For this, define the eigen spaces corresponding to these eigen values.

(Refer Slide Time: 14:44)

The  $W_1$ , in the null space corresponding to the Eigen value 2, it is  $A - 2I$  and we have found in the last lecture, that this consist of all vectors of the form  $\alpha$ ,  $\beta$ ,  $-2\alpha + \beta$ , where  $\alpha$  and  $\beta$  real. And we found an orthonormal basis  $B_1$ , orthonormal basis for  $W_1$ . We found there will be two vectors,  $\varphi_1$  and  $\varphi_2$ . Because the multiplicity is 2 corresponding to the Eigen value  $\lambda = 1$ , there will be  $\varphi_1$  and  $\varphi_2$ . The  $\varphi_1$  we found as  $\frac{1}{\sqrt{5}}$  into  $1, 0, -2$  and the other we found as  $\frac{1}{\sqrt{30}}$  into  $2, 5, 1$ . These are the two, two orthonormal vectors, which form a basis for the eigen space corresponding to the eigen value  $\lambda = 1$ , which we have found in the previous lectures.

(Refer Slide Time: 15:59)

$$W_2 = \text{Null Space } (A - 8I)$$
$$= \left\{ x = \begin{pmatrix} 2\gamma \\ -\gamma \\ \gamma \end{pmatrix} : \gamma \in \mathbb{R} \right\}$$
$$\phi_1^{(2)} = \frac{1}{\sqrt{6}} \begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix}$$

Similarly,  $w_2$  is the eigen space corresponding to the eigen value 8, so it is the null space of  $A - 8I$ , and we found this to be consisting of all vectors of the form  $x$  is equal to  $2\gamma$ , minus  $\gamma$ ,  $\gamma$ ; the  $\gamma$  is real. And there is going to be only one, the dimension being 1, there is going to be only one orthonormal basis for that, and this we found to be  $\frac{1}{\sqrt{6}} (2, -1, 1)$ . So, we have the three Eigen values. Now, we and one of them is repeated twice, two, two are the Eigen values and then, the other Eigen values  $(\lambda_1, \lambda_2)$  corresponding to them.

We have the three Eigen vectors, we call the, this corresponds to the  $\lambda_1$  equal to 2. This also corresponds to  $\lambda_1$  equal to 2, and this corresponds to  $\lambda_1, \lambda_2$ , equal to 8.

(Refer Slide Time: 17:05)

$$\varphi_1^{(2)} = \frac{1}{\sqrt{6}} \begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix}$$

$\lambda_2 = 8$

$$\varphi_1^{(0)} \otimes \varphi_1^{(0)} = \frac{1}{\sqrt{5}} \begin{pmatrix} 1 \\ 0 \\ -2 \end{pmatrix} \frac{1}{\sqrt{5}} \begin{pmatrix} 1 & 0 & -2 \end{pmatrix}$$

Now, we form the  $((\ ))$  the tensor products corresponding to each one of these Eigen vectors. So, we first calculate  $\varphi_1^{(0)} \otimes \varphi_1^{(0)}$ , and what is  $\varphi_1^{(0)}$ ? It is just the  $\frac{1}{\sqrt{5}}$  times  $\varphi_1^{(0)}$ , which is  $\frac{1}{\sqrt{5}}$  times  $\begin{pmatrix} 1 & 0 & -2 \end{pmatrix}$ . Remember, everything is real here, so we have to look at the transpose.

(Refer Slide Time: 17:44)

$$\varphi_1^{(0)} \otimes \varphi_1^{(0)} = \frac{1}{\sqrt{5}} \begin{pmatrix} 1 \\ 0 \\ -2 \end{pmatrix} \frac{1}{\sqrt{5}} \begin{pmatrix} 1 & 0 & -2 \end{pmatrix}$$

$$= \frac{1}{5} \begin{pmatrix} 1 & 0 & -2 \\ 0 & 0 & 0 \\ -2 & 0 & 4 \end{pmatrix}$$

$$\varphi_2^{(0)} \otimes \varphi_2^{(0)} = \frac{1}{\sqrt{30}} \begin{pmatrix} 2 \\ 5 \\ 1 \end{pmatrix} \frac{1}{\sqrt{30}} \begin{pmatrix} 2 & 5 & 1 \end{pmatrix}$$

And the matrix is 1 by 5. If we carry out the product we get this matrix, we have done this in previous lecture also, so it is a simple matrix multiplication, we get this. Similarly, we look at the, again the first Eigen value itself. But look at its second Eigen vector and take the cartesian or the tensor product, it is  $\frac{1}{\sqrt{30}}$  times  $\begin{pmatrix} 2 & 5 & 1 \end{pmatrix}$  into the transpose of that.

(Refer Slide Time: 18:21)

$$= \frac{1}{30} \begin{pmatrix} 4 & 10 & 2 \\ 10 & 25 & 5 \\ 2 & 5 & 1 \end{pmatrix} \text{ Real Symm}$$

$$\varphi_1^{(2)} \otimes \varphi_1^{(2)} = \frac{1}{\sqrt{6}} \begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix} \frac{1}{\sqrt{6}} \begin{pmatrix} 2 & -1 & 1 \end{pmatrix}$$

$$= \frac{1}{6} \begin{pmatrix} 4 & -2 & 2 \\ -2 & 1 & -1 \\ 2 & -1 & 1 \end{pmatrix}$$

And when we carry out the multiplication we get, 1 by 30 into 4, 10, 2, 10, 25, 5, 2, 5, 1. Notice, that this is a Hermitian or as real symmetric matrix. This is what we observed, that when you take Hermitian vector in  $c^n$  and tensor with itself we get a Hermitian matrix. And the real case, if we take a real vector and tensor it with itself we get a real symmetric matrix; again, this is a real symmetric matrix.

And then, finally we look at the Eigen vector corresponding to the second Eigen value, and do the tensor calculation with respect to the, it is 2, minus 1, 1, 1 by root 6 into 1 by root 6, the rho vector, 2, minus 1, 1. Then, we carry out this product we get 1 by 6, 4, minus 2, minus 2, 1, minus 1, 2, minus 1, 1.

(Refer Slide Time: 19:31)

$$\lambda_2 = 8$$

$$\varphi_1^{(0)} \otimes \varphi_1^{(0)} = \frac{1}{\sqrt{5}} \begin{pmatrix} 1 \\ 0 \\ -2 \end{pmatrix} \frac{1}{\sqrt{5}} \begin{pmatrix} 1 & 0 & -2 \end{pmatrix}$$

$$= \frac{1}{5} \begin{pmatrix} 1 & 0 & -2 \\ 0 & 0 & 0 \\ -2 & 0 & 4 \end{pmatrix} \text{ Real Symm}$$

$$\varphi_2^{(0)} \otimes \varphi_2^{(0)} = \frac{1}{\sqrt{30}} \begin{pmatrix} 2 \\ 5 \\ 1 \end{pmatrix} \frac{1}{\sqrt{30}} \begin{pmatrix} 2 & 5 & 1 \end{pmatrix}$$

Now, this corresponds to still the Eigen value lambda 1 equal to 2 and this corresponds to the Eigen value lambda 1 equal to 2 and the last one corresponds to lambda 2 equal to 8. Now, having constructed the tensor products of each one of these Eigen vectors, we multiplied them by the corresponding Eigen values.

(Refer Slide Time: 19:52)

The screenshot shows a digital whiteboard with the following handwritten content:

$$\varphi_1 \otimes \varphi_1 = \frac{1}{\sqrt{6}} \begin{pmatrix} -1 \\ 1 \end{pmatrix} \frac{1}{\sqrt{6}} \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

$$= \frac{1}{6} \begin{pmatrix} 4 & -2 & 2 \\ -2 & 1 & 1 \\ 2 & -1 & 1 \end{pmatrix} \quad \leftarrow \lambda_2 = 8$$

---

$$\lambda_1 \varphi_1^{(0)} \otimes \varphi_1^{(0)} + \lambda_1 \varphi_2^{(0)} \otimes \varphi_2^{(0)} + \lambda_2 \varphi_1^{(2)} \otimes \varphi_1^{(2)}$$

Below the equations, there are arrows pointing from the eigenvalues  $\lambda_1$  and  $\lambda_2$  to their respective values 2 and 8.

So, we look at lambda 1. This phi 1 1 corresponds to Eigen value 1 lambda 1. The phi 1 2 also corresponds to the Eigen value lambda 1 and the phi 2 1 corresponds to the Eigen value lambda 2. Lambda 1 is 2, lambda 1 is 2, lambda 2 is 8 and we have calculated the tensor products above.

(Refer Slide Time: 20:26)

The screenshot shows a digital whiteboard with the following handwritten content:

$$= \begin{pmatrix} 2 & 0 & -2/5 \\ 0 & 0 & 0 \\ -4/5 & 0 & 8/5 \end{pmatrix} + \begin{pmatrix} 4/5 & 10/5 & 2/5 \\ 10/5 & 25/5 & 5/5 \\ 2/5 & 5/5 & 1/5 \end{pmatrix}$$

Below the first matrix is the label  $\lambda_1 \varphi_1^{(0)} \otimes \varphi_1^{(0)}$  and below the second matrix is  $\lambda_1 \varphi_2^{(0)} \otimes \varphi_2^{(0)}$ .

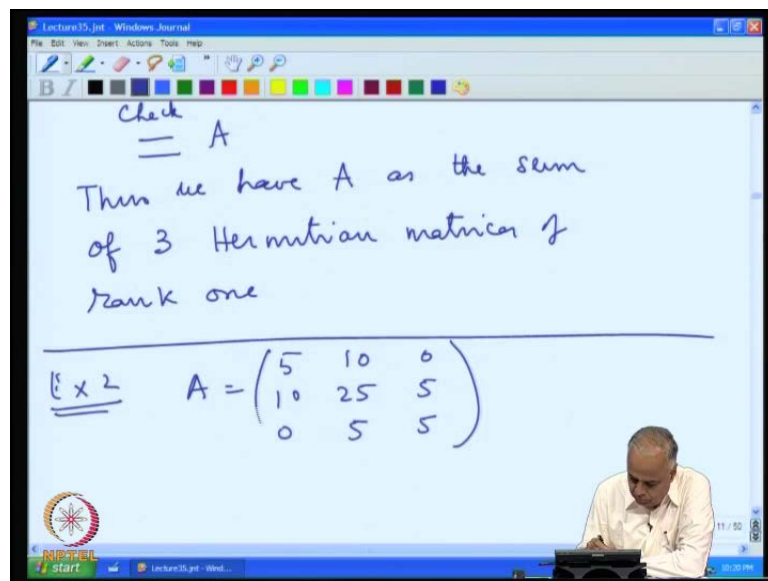

$$+ \begin{pmatrix} 16/3 & -8/3 & 8/3 \\ -8/3 & 4/3 & -4/3 \\ 8/3 & -4/3 & 4/3 \end{pmatrix}$$

Below the third matrix is the label  $\lambda_2 \varphi_1^{(2)} \otimes \varphi_1^{(2)}$ .

When you substitute all that, we get the summation as 2 by 5, 0, minus 2 by 5, 0, 0, minus 4 by 5, 0, 8 by 5 plus 4 by 15, 10 by 15, 2 by 15, 10 by 15, 25 by 15, 5 by 15, 2 by 15, 5 by 15, 1 by 15. These are the two terms corresponding to the first Eigen value. This is  $\lambda_1$ ; this is the term, which is  $\lambda_1 \phi_1 \phi_1^T$  with the value  $\lambda_1$  equal to 2 and  $\phi_1$  tensor  $\phi_1$ , which we have found above. This is  $\lambda_1$  again, with  $\lambda_1$  equal to 2, but  $\phi_2$  tensor  $\phi_2$  plus the next one is the other Eigen value, which is 16 by 3 minus 8 by 3 8 by 3 minus 8 by 3 4 by 3 minus 4 by 3 8 by 3 minus 4 by 3 4 by 3. Now, this is the term, which is  $\lambda_2 \phi_2 \phi_2^T$ .

And when we add all this we get check, this exactly adds up to the given matrix A. Now, notice, that the first matrix we have here is of rank 1, because every rho is a multiple of the first rho. Similarly, the second matrix is a matrix of rank 1, because every rho is a multiple of the third rho and the third matrix is a multiple of either matrix of rank 1 because every rho is a multiple of the third rho. Observe also, that each one of this is a Hermitian matrix.

(Refer Slide Time: 22:37)

Thus, we have A as the sum of three Hermitian matrices of rank one. Now, we have three of them because the rank of the matrix was three. So, whenever we have rank rho, you will have rho matrix for which we will take of each of rank one.

Let us look at another example, A equal to 5, 10, 0, 10, 25, 5, 0, 5, 5.

(Refer Slide Time: 23:28)

The screenshot shows a digital whiteboard with the following handwritten text:

$$C_A(\lambda) = (\lambda - 30)(\lambda - 5)\lambda$$
$$\lambda_1 = 30 \quad a_1 = 1$$
$$\lambda_2 = 5 \quad a_2 = 1$$
$$\lambda_3 = 0 \quad a_3 = 1$$

A has nullity 1  
 $\therefore$  A has rank 2 (real symm)

The slide also features a toolbar at the top with various drawing tools and a small inset video of a man in a white shirt at the bottom right.

Now, if we calculate the characteristic polynomial we get lambda minus 30 into lambda minus 5 into lambda. If we write down the determinant lambda minus A and expand it, you will see, that it can be factored as,  $((\lambda - 30)(\lambda - 5)\lambda)$  lambda equal to lambda minus 30 into lambda minus 5.

What are the Eigen values? Lambda 1 equal to 30, algebraic multiplicity 1; lambda 2 equal to 5, algebraic multiplicity is 1. Notice, that lambda 3 is 0, which means, that A has nullity 1, because lambda equal to 0 is an Eigen value of multiplicity 1 and therefore, A has rank, the matrix is 3 by 3, nullity is 1. So, the rank is 3 minus 1, which is 2, therefore A is real symmetric and has rank 2.

(Refer Slide Time: 24:37)

The screenshot shows a digital whiteboard with the following handwritten text:

A has nullity 1  
 $\therefore$  A has rank 2 (real symm)

We shall decompose this as the sum of Two Hermitian matrices each of rank one.

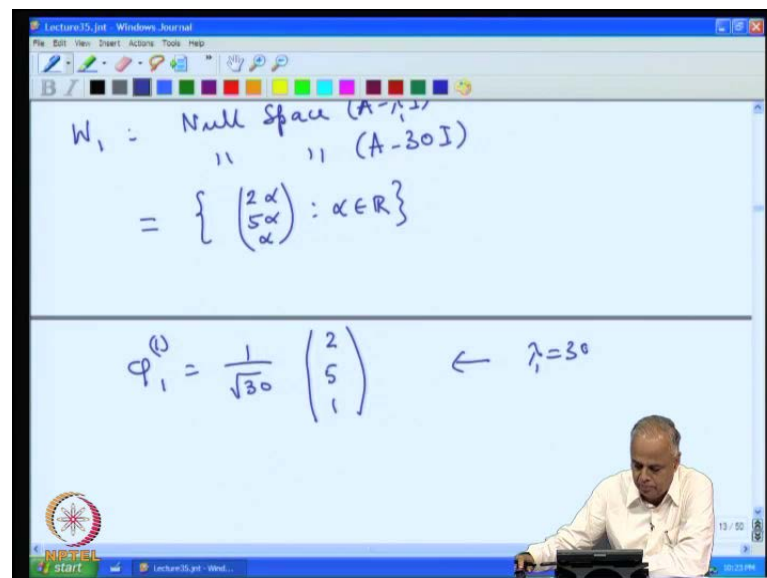

$$W_1 = \text{Null Space } (A - \lambda_1 I)$$
$$'' \quad '' \quad (A - 30I)$$

The slide also features a toolbar at the top with various drawing tools and a small inset video of a man in a white shirt at the bottom right.

And therefore, we have, we shall decompose this as the sum of, now since the rank is two even though the matrix is 3 by 3. Since the rank is two, we decompose there the sum of two Hermitian matrices, each of rank one.

Now, how do we do the decomposition? Once again we require, notice, that as we observed in the beginning, when you do this decomposition, the terms in the decomposition corresponding to the Eigen value zero disappear because we multiply by the Eigen value. So, we have to only concentrate on the non-zero Eigen values. Therefore, we must look at only the null space of the first two Eigen values. The first Eigen value is, thus, the null space of A minus 30I because the first Eigen value was 30.

(Refer Slide Time: 25:46)

And it can be shown, you can easily compute the solutions to be of the form 2 alpha, 5 alpha, 1 as alpha belongs to R and therefore, an orthonormal basis for that is 1 by root 30 into 2, 5, 1. So, that is corresponding to lambda 1 equal to 30.

(Refer Slide Time: 26:18)

$$\phi_1 = \frac{1}{\sqrt{30}} \begin{pmatrix} 2 \\ 5 \\ 1 \end{pmatrix}$$

$$W_2 = \text{Null space } (A - 5I)$$

$$= \left\{ \begin{pmatrix} \beta \\ 0 \\ -2\beta \end{pmatrix} : \beta \in \mathbb{R} \right\}$$

$$\phi_1^{(2)} = \frac{1}{\sqrt{5}} \begin{pmatrix} 1 \\ 0 \\ -2 \end{pmatrix}$$

Then, we look at  $W_2$ , which is the null space of  $A$  minus the second Eigen value, which is  $5I$ . Now, we tensor, we can verify, that again this is consisting of all the vectors of this form and the corresponding orthonormal Eigen vector is  $1, 0, \text{ minus } 2$ .

Now, in the decomposition, only the Eigen vectors corresponding to the non-zero Eigen values appear. So, we do not have to worry about  $W_3$ , because  $W_3$  is the eigen space corresponding to the Eigen value  $0$ .

(Refer Slide Time: 27:04)

$$\phi_1^{(1)} \otimes \phi_1^{(1)} = \frac{1}{\sqrt{30}} \begin{pmatrix} 2 \\ 5 \\ 1 \end{pmatrix} \frac{1}{\sqrt{30}} \begin{pmatrix} 2 \\ 5 \\ 1 \end{pmatrix}$$

$$= \frac{1}{30} \begin{pmatrix} 4 & 10 & 2 \\ 10 & 25 & 5 \\ 2 & 5 & 1 \end{pmatrix} \quad \leftarrow \hat{=} 30$$

$$\phi_1^{(2)} \otimes \phi_1^{(2)} = \frac{1}{\sqrt{5}} \begin{pmatrix} 1 \\ 0 \\ -2 \end{pmatrix} \frac{1}{\sqrt{5}} \begin{pmatrix} 1 \\ 0 \\ -2 \end{pmatrix}$$

Now, we compute  $\phi_1$  tensor  $\phi_1$ , which is  $1$  by  $\sqrt{30}$  into  $2, 5, 1$  into  $1$  by  $\sqrt{30}$  into  $2, 5, 1$ , which we have calculated earlier in the previous example, and it turns out to

be 1 by 30, 4, 10, 2, 10, 25, 5, 2, 5, 1. This is the same as what was obtained in the previous example and this corresponds to, we keep reminding, that this corresponds to the Eigen value 30.

Similarly, the 2nd Eigen value we calculate the tensor  $\phi_1^{(2)}, \phi_1^{(2)}$ , which is 1 by root 5 into 1, 0, minus 2 into 1 by root 5 into 1, 0, minus 2.

(Refer Slide Time: 27:59)

Handwritten notes on a digital whiteboard:

$$= \frac{1}{30} \begin{pmatrix} 4 & 10 & 2 \\ 10 & 25 & 5 \\ 2 & 5 & 1 \end{pmatrix} \leftarrow \lambda_1 = 30$$

$$\phi_1^{(2)} \otimes \phi_1^{(2)} = \frac{1}{\sqrt{5}} \begin{pmatrix} 1 \\ 0 \\ -2 \end{pmatrix} \frac{1}{\sqrt{5}} \begin{pmatrix} 1 & 0 & -2 \end{pmatrix}$$

$$= \frac{1}{5} \begin{pmatrix} 1 & 0 & -2 \\ 0 & 0 & 0 \\ -2 & 0 & 4 \end{pmatrix} \leftarrow \lambda_2 = 5$$

Again, we have calculated this in the earlier example, it turns out to be 1, 0, minus 2, 0, 0, 0, minus 2, 0, 4 and this corresponds to the eigenvalue lambda.

Handwritten notes on a digital whiteboard:

Decomposition

$$\lambda_1 \phi_1^{(0)} \otimes \phi_1^{(0)} + \lambda_2 \phi_1^{(2)} \otimes \phi_1^{(2)}$$

$\downarrow$   
 $30$

$$\begin{pmatrix} 4 & 10 & 2 \\ 10 & 25 & 5 \\ 2 & 5 & 1 \end{pmatrix} + \begin{pmatrix} 1 & 0 & -2 \\ 0 & 0 & 0 \\ -2 & 0 & 4 \end{pmatrix}$$

Check A

Now, for the decomposition we have, therefore how does the decomposition look like? We have to look at the lambda 1, the tensor product of the Eigen vectors must be multiplied by the corresponding eigenvalue and they have only two non-zero1s here. Now, we have lambda 1 is 30, lambda 2 is 5. So, if we now multiply this by 30, this has to be multiplied by 30, so the 1 by 30 and 30 get cancelled, we get 4, 10, 2, 10, 25, 5 and 2, 5, 1. And then, when we multiply this matrix by 5, the 1 by 5 gets cancelled we get 1, 0, minus 2, 0, 0, 0, minus 2, 0, 4. And when we add, check this is exactly equal to the given matrix here.

Notice, that each one of the matrices in above sum is a Hermitian matrix, real symmetric in this case. And the first matrix is of rank one because every row is a multiple of the 3rd row and a 2nd matrix is of rank one because every row is a multiple of the 1st row.

(Refer Slide Time: 29:39)

So, therefore, we have expressed A as the sum of two Hermitian matrices, in this case real symmetric matrices because you are with real symmetric, real symmetric matrices, each of rank one.

And why do we have only two matrices in the sum or two terms in the sum? It is because of rank two. So, thus, if we have a Hermitian matrix of rank rho, it can be always split into your sum of rho terms of rho matrix. Each matrix is Hermitian, each matrix is of rank 1, so rank rho matrix is the sum of row one rank matrices, so the ranks can be split. This is the decomposition of a Hermitian matrix into rank 1 matrices, which we saw last time. These are the two examples.

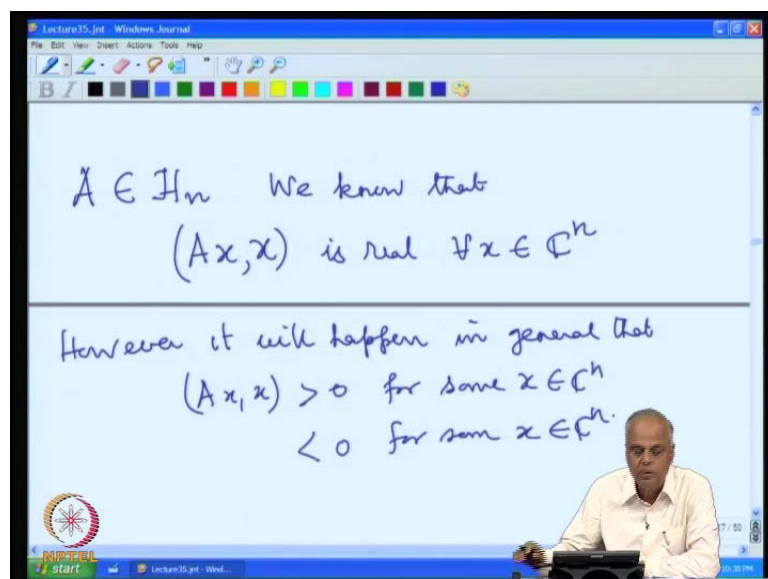

(Refer Slide Time: 30:50)

Now, we look at a special class of Hermitian matrices; special class of Hermitian matrices. Now, first we looked at all  $n$  by  $n$  matrices, then we saw the various diagonalizability criteria, namely  $a_m$  equal to  $g_m$  and then we found, that there are matrix for which  $a_m$  may not be equal to  $g_m$ . Therefore, all  $n$  by  $n$  matrices are not diagonalizable. Then, we looked at a special class of  $n$  by  $n$  matrices, namely Hermitian matrix where diagonalizability was guaranteed.

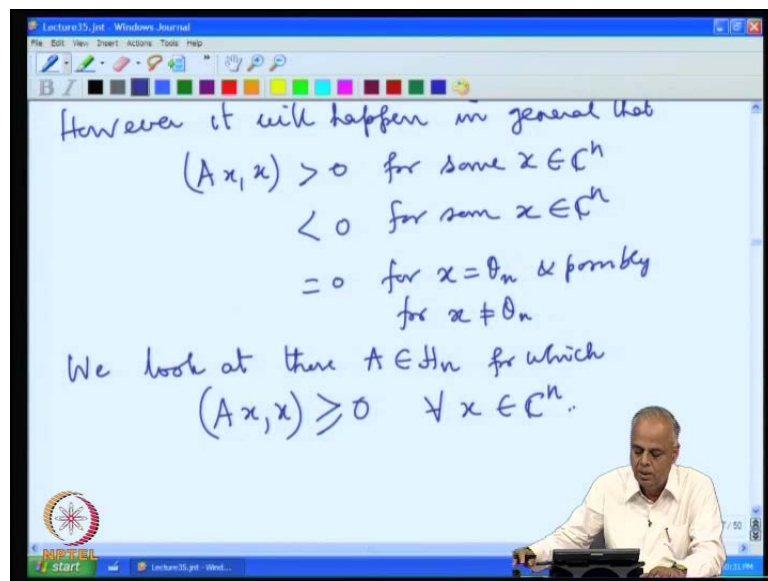

Now, inside this Hermitian matrix class we are going to look at a special class. So, we had first the collection of all  $n$  by  $n$  matrices, in that we had the  $H_n$ , the Hermitian matrices. Now, we are going to look at a sub-class of the Hermitian matrices.

(Refer Slide Time: 31:54)

Now, suppose I take any Hermitian matrix. We know, that one of the fundamental properties of Hermitian matrices is that  $(Ax, x)$  is real for every  $x$  in  $\mathbb{C}^n$ . If you take even a complex matrix  $n$  by  $n$  and even a complex vector  $x$ , as long as the matrix is Hermitian  $(Ax, x)$  always turns out to be real. This is a typical property of Hermitian matrix. So, for Hermitian matrices,  $(Ax, x)$  is always real. However, it may, it will happen in general, that  $(Ax, x)$  is positive for some  $x$ , negative for some  $x$  and of course, is obviously 0 for  $x$  equal to 0,  $x$  equal to 0 for  $x$  equal to  $\theta_n$ .

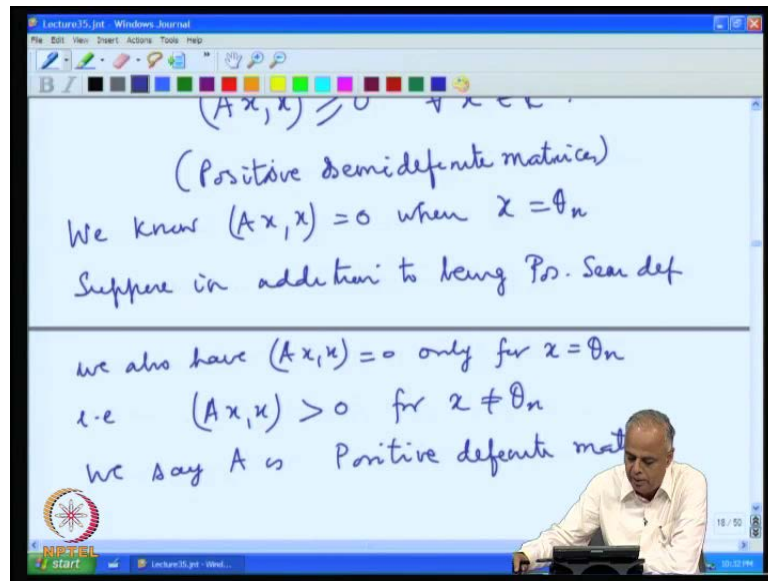

(Refer Slide Time: 33:11)

And possibly, for  $x$  not equal to  $\theta_n$ . So, in general even though we know, that  $(Ax, x)$  is real, we cannot say precisely, whether it is going to be positive or negative. For a general Hermitian matrix it could turn out to be positive for some  $x$ , negative for some  $x$  and zero for some.

Now, we are going to look at a special subclass for which it always maintains the same sign. So, we look at those  $A$ , which are Hermitian, a number we write here belongs to  $H_m$ , what we mean is that  $A$  is a Hermitian matrix. So, we look at those  $A$  in  $H_m$  for which  $(Ax, x)$  is always greater than or equal to 0 for every  $x$  in  $\mathbb{C}^n$ . Such matrices are called positive.

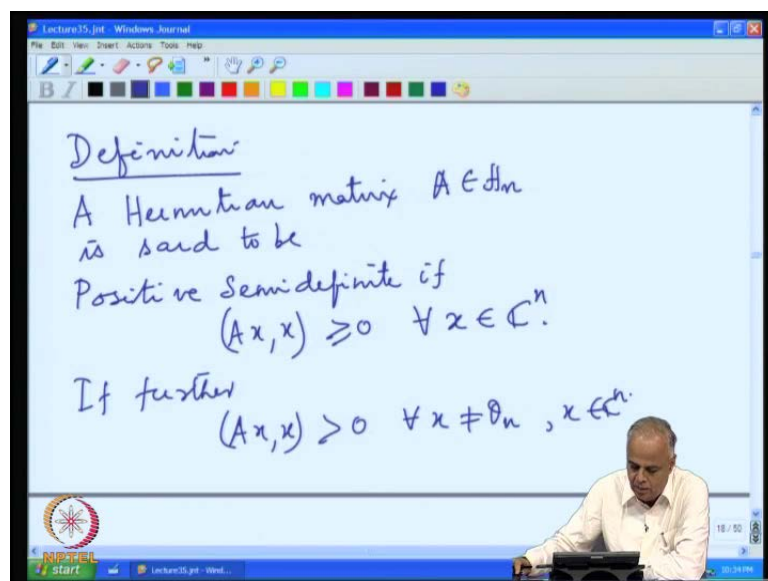

(Refer Slide Time: 34:26)

We will write the formal definition, positive semi-definite matrix.

Now, we know, that  $(Ax, x)$  is 0 when  $x$  is equal to  $\theta_n$ . We know,  $(Ax, x)$  is equal to 0 where  $x$  is the 0 vector. Suppose, in addition to being positive semi-definite, we also have 0 is the only vector for only, for  $x$  equal to  $\theta_n$ , which means what? It is always greater than or equal to 0 and equal to 0 only for  $x$  equal to  $\theta_n$ , that is,  $(Ax, x)$  will be strictly positive for  $x$  not in 0. We, then we say  $A$  is positive definite.

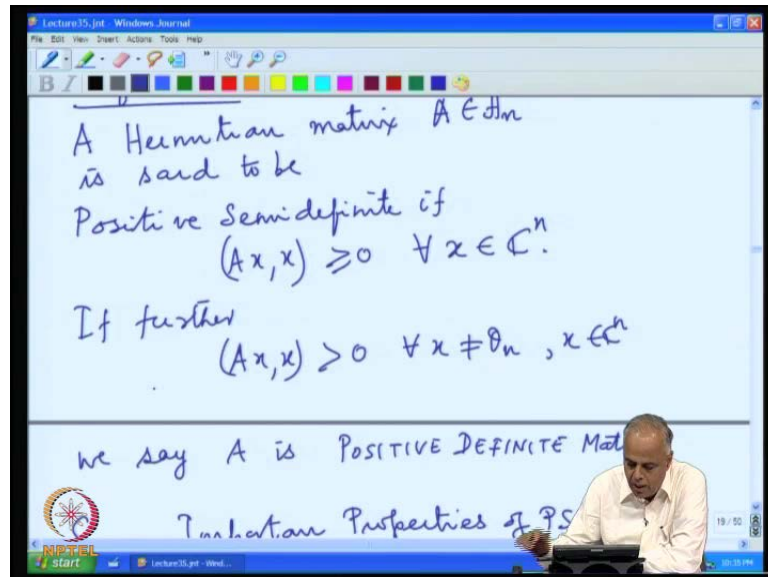

(Refer Slide Time: 35:44)

So, we will write the formal definition. So, definition, first of all, all these notions are positive semi-definite, positive definite. We are introducing only for Hermitian matrix.

So, a Hermitian matrix, that is,  $n$  by  $n$  Hermitian matrix is said to be positive semi-definite if  $(Ax, x)$  is greater than or equal to 0 for every  $x$  belonging to, for every  $x$  belonging to  $\mathbb{C}^n$ .

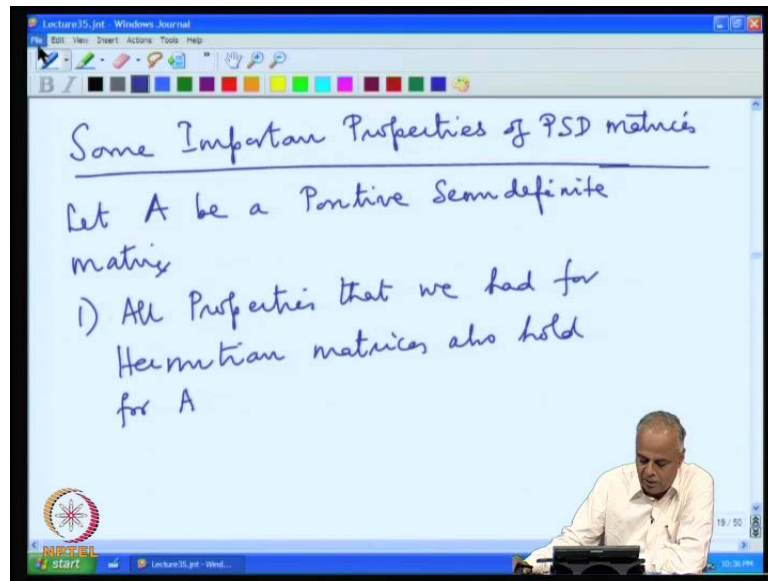

(Refer Slide Time: 37:00)

If further,  $(Ax, x)$  is strictly positive for every  $x$  not equal to  $\theta_n$ ,  $x$  belongs to  $\mathbb{C}^n$ , we say,  $A$  is positive definite matrix.

Analogously, we can define negative semi-definite by replacing greater than or equal to 0 by less than or equal to 0 and negative definite by replacing greater than 0 by less than 0 above. So, we have the notions of positive semi-definite matrices and positive definite matrices. What are the some important properties of such matrix? We are going to use all these properties eventually to analyze a general  $(( ))$  of, I let PSD for positive semi-definite matrix.

(Refer Slide Time: 38:12)

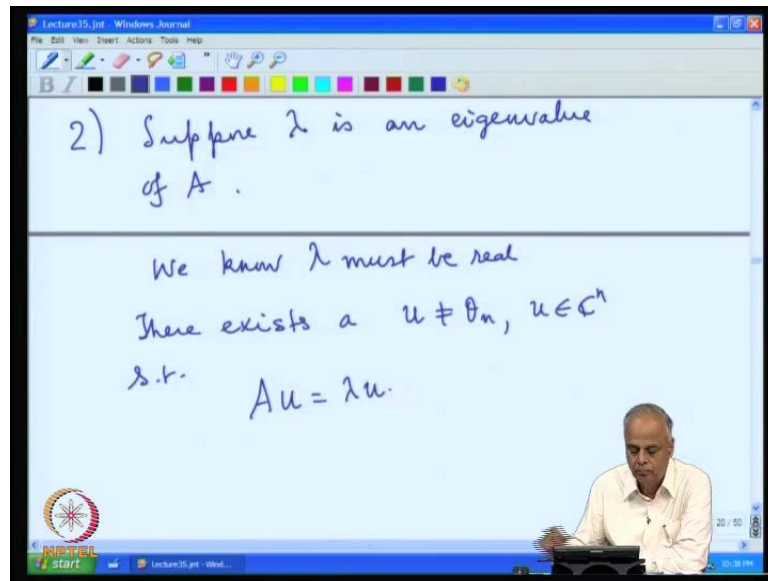

Let  $A$  be a positive semi-definite matrix. Now, we have seen, that the notion of positive definiteness, a priori we assume, that it is a Hermitian matrix and therefore, all properties, that we had for Hermitian matrices also hold for  $A$  because  $A$  is positive semi-definite.

Recall our picture, the positive definite matrices are, what are these? They we are now looking at the positive semi-definite matrices, they are sitting inside the  $H_n$ . So, whatever, properties hold for  $H_n$ , hereditarily they hold for positive semi-definite matrix, all the properties that we had for Hermitian matrix. What are some of the properties? Eigen values will be real; Eigen vectors corresponding to distinct Eigen values will be orthogonal; algebraic multiplicity will be equal to geometric multiplicity for all Eigen values, the matrix, if it has rank  $\rho$  can be decomposed in terms of  $\rho$  1 rank matrix.

All these properties will now sweepingly, can be applied for positive semi-definite, but that is only hereditary. They have acquired this property by being Hermitian matrices. What are the properties, that they have going to get in addition to all these properties as extra properties because they are positive semi-definite. These properties are specific to positive semi-definite matrices.

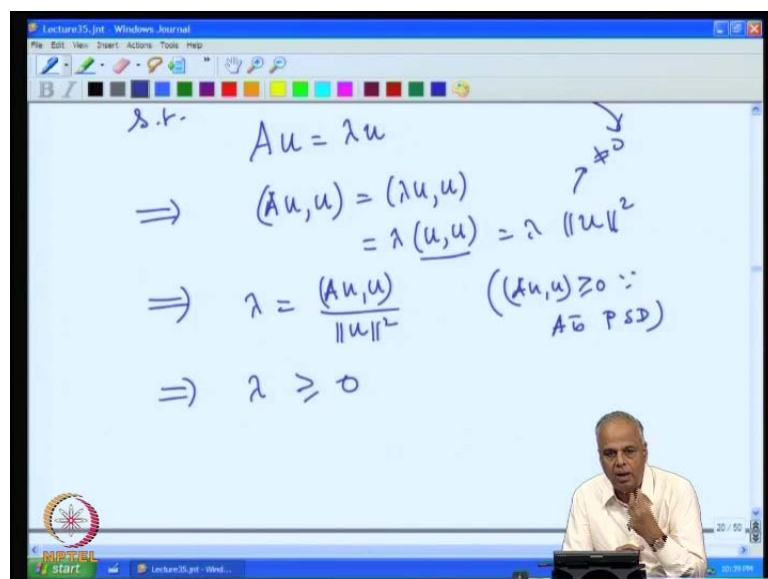

(Refer Slide Time: 39:55)

Now, suppose  $\lambda$  is an Eigen value of  $A$ , so I have a positive semi-definite matrix and I consider an Eigen value of  $A$ . I, we know  $\lambda$  must be real, why  $\lambda$  should be real? Because  $A$  is positive definite and therefore, it is Hermitian and we know, that the Eigen values of Hermitian matrices are real and therefore,  $\lambda$  must be real.

So, once it is real, either it is positive or it is negative or it is zero, you would like to make some statement about the sign of the Eigen values. Now, because  $\lambda$  is an Eigen value, there exists an Eigen vector such that  $Au = \lambda u$ .

(Refer Slide Time: 41:00)

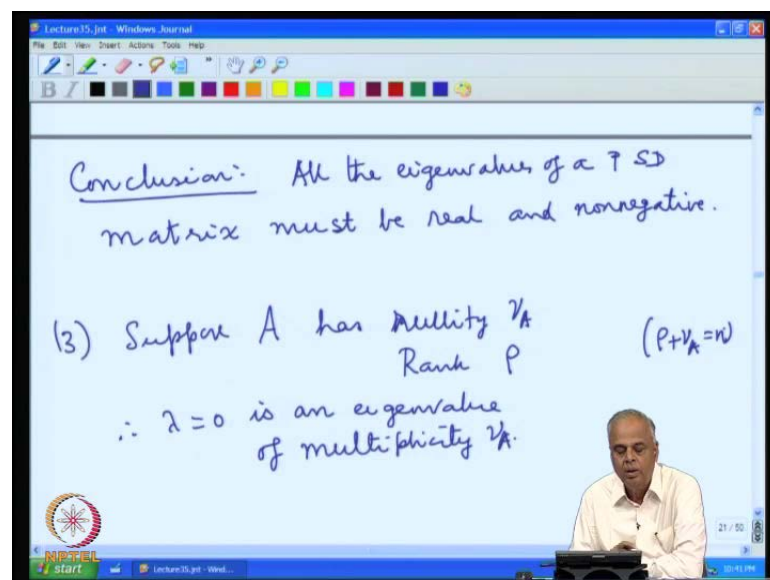

Now, that says, if I now take the inner product of  $u$ , I get  $(\lambda u, u)$ . Now,  $\lambda$  is a constant, it can be pulled out. Now,  $(u, u)$  cannot be 0 because  $u$  is a non-zero vector and therefore, a non-zero vector inner product with itself will give a length of  $u$  square and therefore, the length  $u$  will not be zero. If  $u$  is not 0 and so,  $(u, u)$  is not zero. We will write it as this non  $u$  square cannot be 0 because of  $u$  being not theta m. Therefore, we can divide by non  $u$  square, we get  $\lambda$  equal to  $(A u, u)$  by non  $u$  square.

So, the  $\lambda$  is the ratio of these two quantities, but now since  $A$  is positive semi-definite, this is the time we are using the property, that  $A$  is positive semi-definite. This is precisely the place there we use the fact, that  $A$  is positive semi-definite. Since,  $A$  is positive semi-definite, the numerator is greater than or equal to zero because  $A$  is positive semi-definite and the denominator is automatically greater than or equal to zero because length square. So, it is a ratio of two non-negative quantities that says, that should also be greater than or equal to zero.

So, therefore, we have in addition to being the Eigen value being real, we have the fact, that Eigen value cannot be negative, it has to be non-negative, it is either zero or positive.

(Refer Slide Time: 42:46)

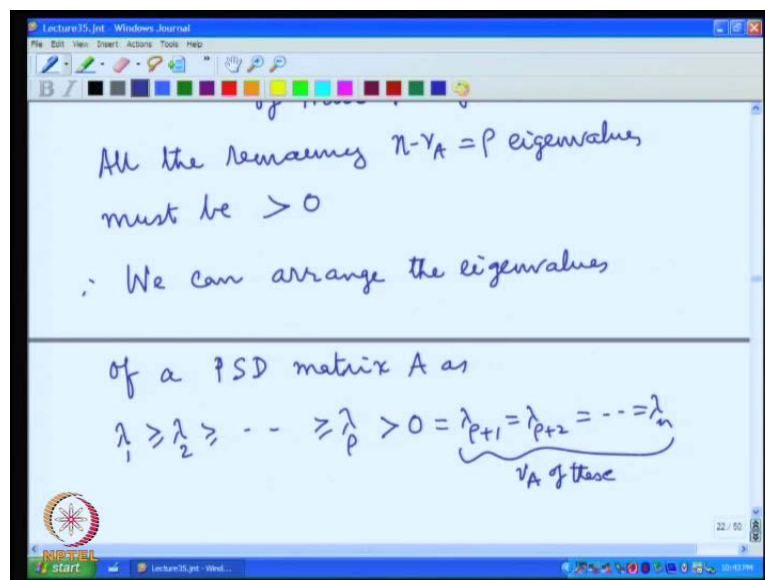

So, the conclusion is, all the Eigen values of a positive semi-definite matrix must be real and non-negative. Now, zero can become an Eigen value only if the null space has non-zero vectors only if nullity is greater than or equal to 1. Therefore, we have all the Eigen values of the positive semi-definite matrix or real and non-negative.

Now, what are the consequences of this? Suppose, again we are all looking at positive,  $A$  is always a positive semi-definite matrix, so  $A$  has nullity  $\nu_A$ , that is assumed it is, there is some nullity,  $\nu_A$  greater than or equal to. Then, what is rank? Rank is  $\rho$  and we are  $\rho + \nu_A = n$ .

Now, what does it mean to say, that nullity is  $\nu_A$ ? It means  $\lambda = 0$  is an Eigen value;  $\lambda = 0$  is an Eigen value of multiplicity  $\nu_A$ .  $A$  is  $n$  by  $n$  matrix, there must be  $n$  Eigen values,  $\nu_A$  of these Eigen values are 0; 0 appears as an Eigen value  $\nu_A$  times.

Now, how many more Eigen values we require? We require  $n - \nu_A$  Eigen, which is equal to  $\rho$  Eigen values and since all the Eigen values are greater than or equal to 0 and 0 has been taken care of, here all the remaining Eigen values must be positive.

(Refer Slide Time: 44:57)

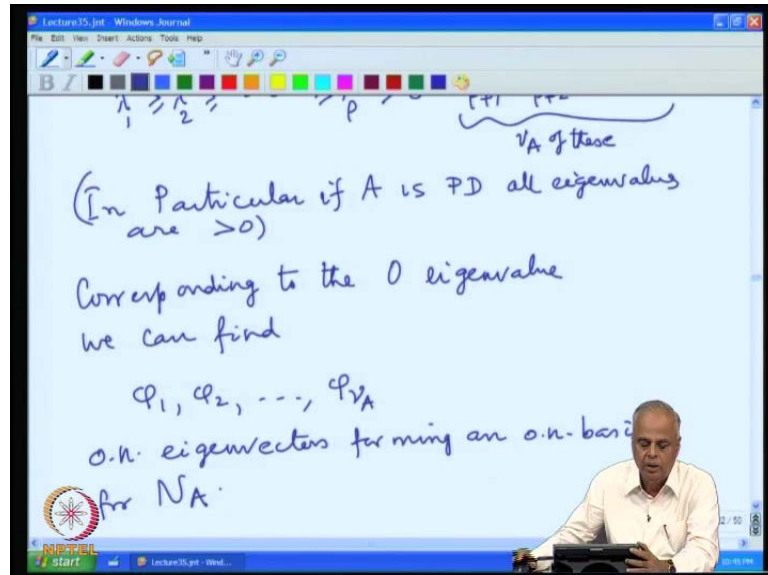

All the remaining  $n - \nu_A = \rho$  eigenvalues must be strictly positive. Therefore, we can arrange the eigenvalues of a positive semi-definite matrix  $A$  as an eigenvalue, may be the next eigenvalue is equal to... and so on. So, there are  $\rho$  eigenvalues, which are all strictly positive and the remaining eigenvalues are all equal to 0. So, there are  $\nu_A$  of them. So,  $\nu_A$  of these eigenvalues is 0 and  $\rho$  of these eigenvalues are positive.

So, therefore, if we have a positive semi-definite matrix of rank  $\rho$ , we can always split the eigenvalues into two groups, one group of eigenvalues, which are all strictly positive

than the eigenvalue zero, the eigenvalue zero because nullity  $\nu_A$  will appear  $\nu_A$  times and all the other eigenvalues put together will give us  $\rho$  eigenvalue.

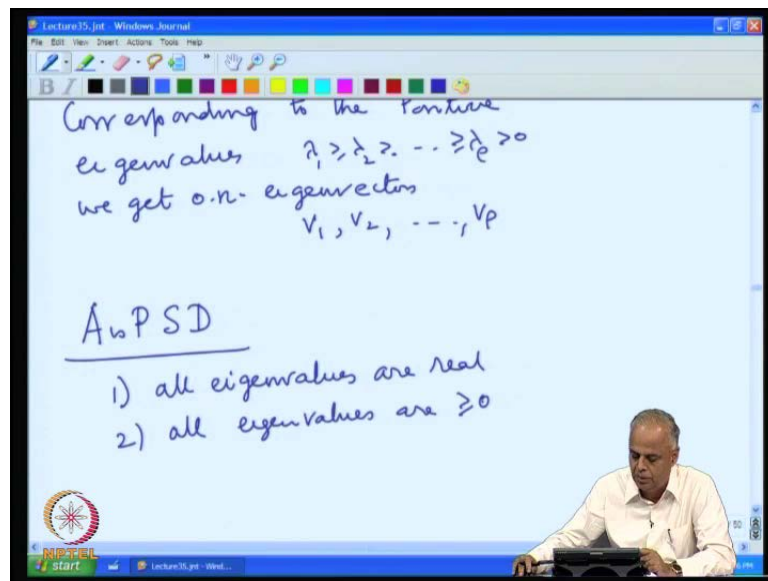

(Refer Slide Time: 46:46)

In particular, if  $A$  is positive definite, then zero is not an eigenvalue at all, all eigenvalues are strictly positive. That means, we will have  $\lambda_1$  greater than or equal to  $\lambda_2$  greater than or equal to up to  $\lambda_n$ , all of them greater than 0. So, the zero eigenvalue will not appear at all.

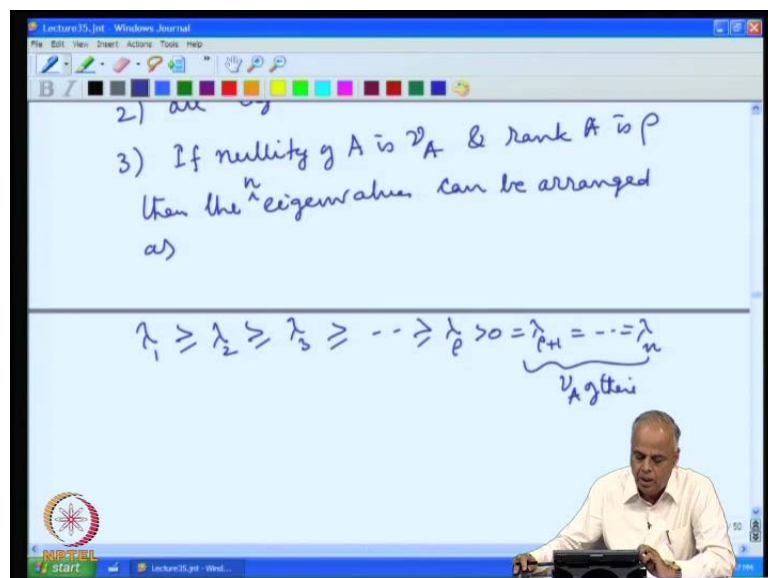

Now, once we have these eigenvalues, because it is Hermitian, we will be able to find corresponding orthonormal Eigen vectors. So, now corresponding to the zero eigenvalues we can find, since multiplicity is  $\nu_A$  we will find  $\nu_A$  will, I will write it as  $\phi_1, \phi_2, \dots, \phi_{\nu_A}$  orthonormal Eigen vectors. And since these are eigenvalues corresponding to the eigenvalue zero forming an orthonormal basis for null space of  $A$ , the Eigen vectors corresponding to the eigenvalue zero will give us a basis, an orthonormal basis for the null space of  $A$  in the case of positive semi-definite matrix.

(Refer Slide Time: 48:36)

Next, corresponding to these positive Eigen values we will get Eigen vectors, say  $v_1, v_2, v_3, \dots, v_p$  and there will be orthonormal because we know, that for Hermitian matrices we can always get the orthonormal Eigen vector. So, corresponding to the positive eigenvalues  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_p > 0$ , we get orthonormal Eigen vectors  $v_1, v_2, \dots, v_p$ . So, therefore, if  $A$  is positive semi-definite, so let us summarize this,  $A$  is positive semi-definite, all eigenvalues are real, all eigenvalues are greater than or equal to 0.

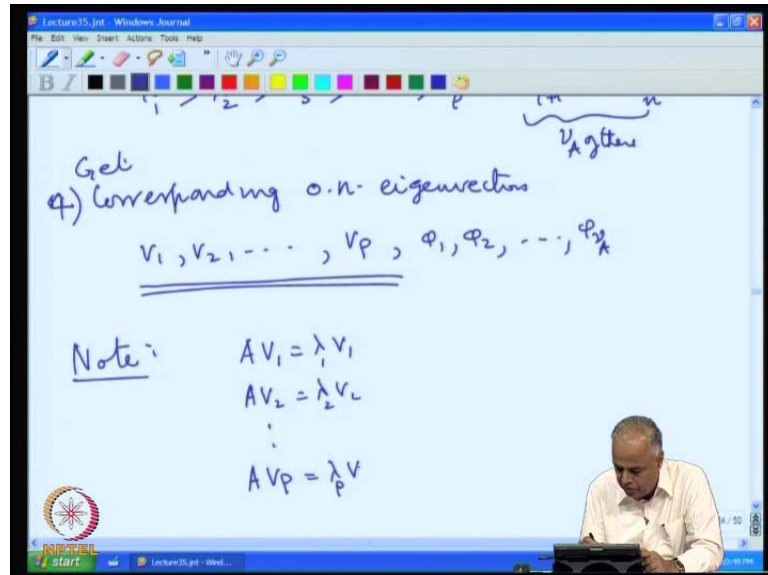

(Refer Slide Time: 49:38)

If, nullity of  $A$  is  $\nu_A$  and rank  $A$  is  $\rho_A$ , then I will just write  $\rho$  here instead of writing subscript,  $A$  is  $\rho$ , then the eigenvalues can be the  $n$  eigenvalues. When I say ((

)) we are looking at multiplicities included, can be arranged as  $\lambda_1$  greater than or equal to  $\lambda_2$  greater than or equal to  $\lambda_3$  greater than or equal to  $\lambda_\rho$  greater than 0 and then  $\lambda_\rho + 1$ . All these eigenvalues are 0 eigenvalues and there are  $n$  A of this.

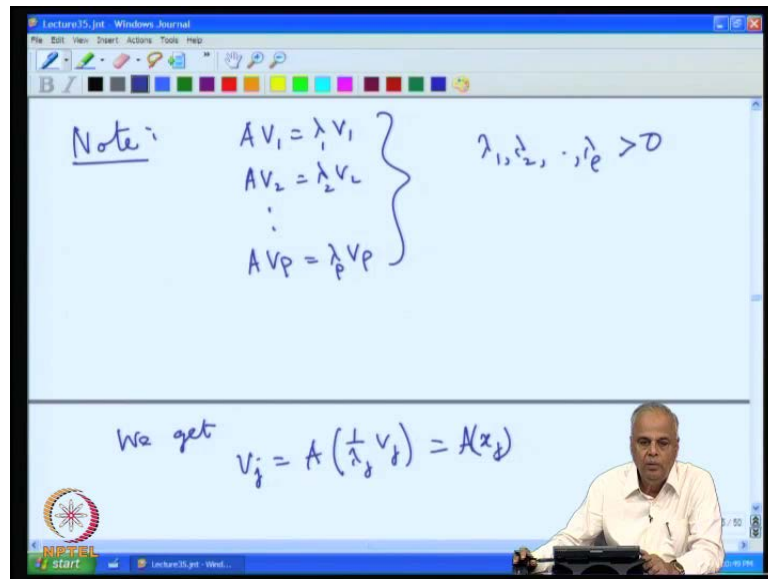

(Refer Slide Time: 50:39)

And corresponding, get corresponding Eigen vectors, orthonormal Eigen vectors  $v_1, v_2, v_\rho, \phi_1, \phi_2, \dots, \phi_\nu$ . Now, these are the basic ingredients that we require to analyze a given matrix. We will see how we can convert all the questions, all the competitions, that we require regarding answering the questions for a general matrix to those of some simple Hermitian positive semi-definite matrix.

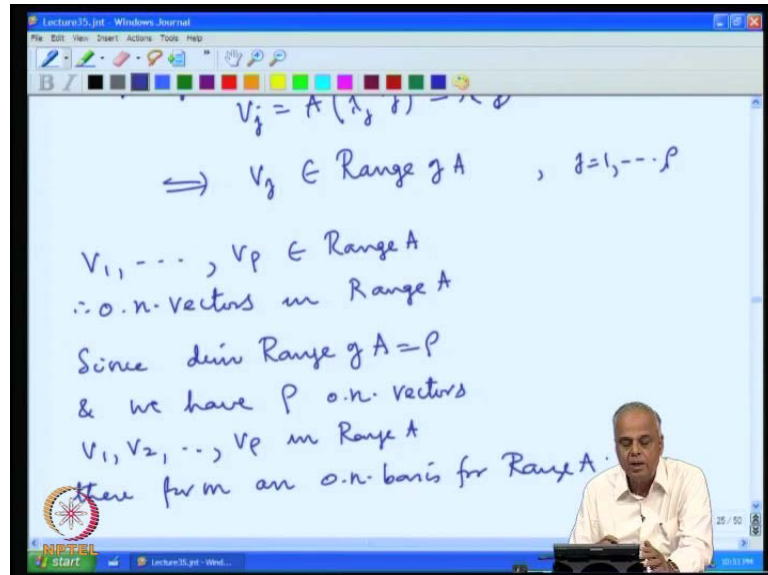

Now, let us look at this  $v_1, v_2, v_r, v_\rho$ . So, note one important property, we are going to observe these.  $v_1$  is an Eigen vector corresponding to  $\lambda_1$ , so we have  $Av_1$  is  $\lambda_1 v_1$ ,  $Av_2$  is  $\lambda_2 v_2$  and there  $Av_\rho$  is  $\lambda_\rho v_\rho$ .

(Refer Slide Time: 52:01)

Now, note that the lambda 1, lambda 2, lambda rho is all the positive eigenvalues and therefore, we can divide. So, we get, for each V j can be written as A of 1 by lambda j V j or we can write it as A of x j, which means, V j is a vector of the form A of something.

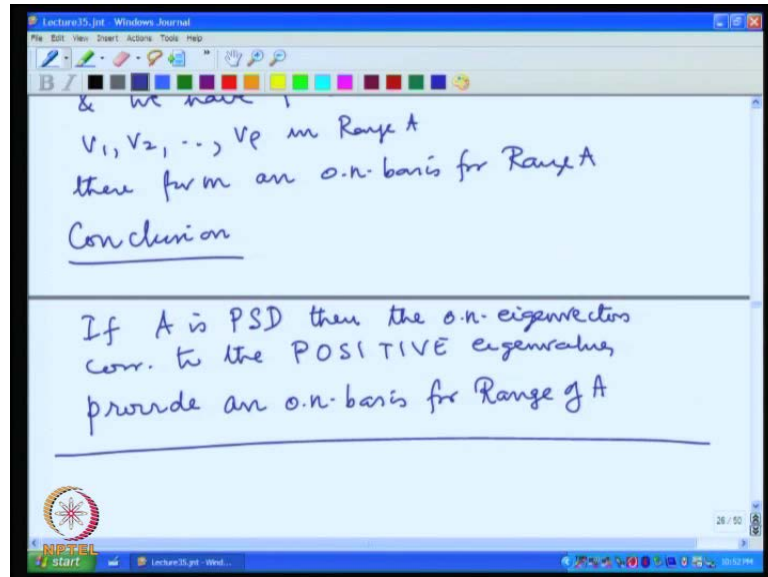

(Refer Slide Time: 52:27)

So, therefore, V j belongs to the range of A. This is true for j equal to 1 to rho and therefore, V 1, V 2, V rho belong to range of A, there orthonormal vectors as we have found in range of A. Therefore, orthonormal vectors in range of A, but what is the range of A? The range of A is the rank, which is rho and therefore, the dimension of the range of A is rho. And we have found rho orthonormal Eigen vectors in that space of dimension rho and therefore, they form an orthonormal basis for range of rho.

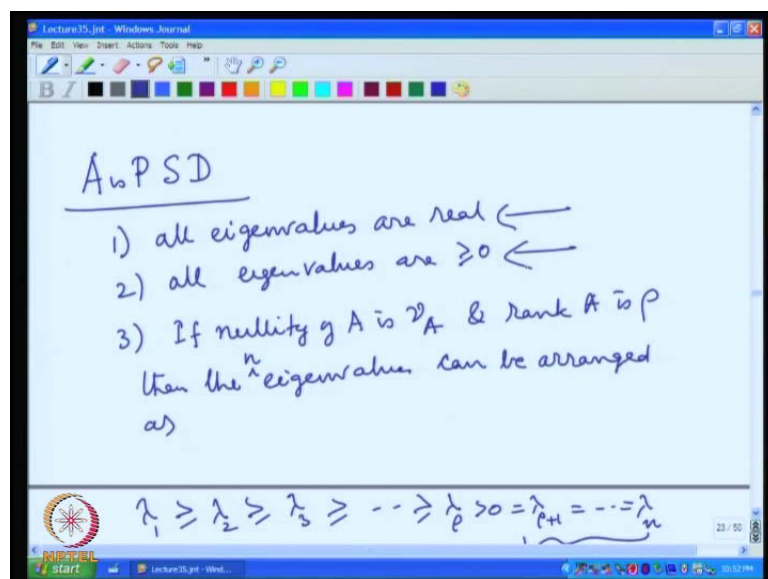

So, since dimension of range of A equal to rho and we have rho orthonormal vectors  $V_1, V_2, \dots, V_\rho$  in range of A, these form an orthonormal basis for range of A. So, we get an orthonormal basis for the range of A from the Eigen vectors corresponding to the non-zero eigenvalues.

(Refer Slide Time: 54:01)

So, that is the important conclusion. If A is positive semi-definite, then the orthonormal Eigen vectors corresponding to the positive eigenvalue, strictly positive eigenvalues. The positive eigenvalues provide an orthonormal basis for range of A.

(Refer Slide Time: 55:14)

Now, we have studied Hermitian matrices, we have studied positive semi-definite matrices, which is a special class of Hermitian matrices. We have found some special properties of the eigenvalues, and the Eigen vectors of positive semi-definite matrices, which we shall again recall.

The first property is that all the eigenvalues are real, all the eigenvalues are greater than or equal to 0, nullity is  $\text{nu } A$ , the Eigen values can be arranged in this form, and corresponding to this we will get the Eigen vectors corresponding to these eigenvalues. These are orthonormal Eigen vectors and the Eigen vectors corresponding to the positive eigenvalues provide us a basis with, for the range of  $A$ . So, now, we have studied this special class of positive semi-definite matrices.

We have seen the notions of vector spaces; we have seen the notion of subspaces. We have seen that any matrix has four subspaces associated with it, two of them in  $\mathbb{R}^n$ , two of them in  $\mathbb{R}^m$ . We have seen that these pairs are orthogonally oriented, so we introduced the notion of orthogonal complements. Then, we introduced the notion of orthonormal basis and then, we had the notion of Hermitian matrices and then, finally, the special class of positive semi definite matrices.

Now, we are in ready in a position, we have got all the ingredients, all the previous and all the material, that we require to analyze a given general  $m$  by  $n$  matrix complex or real. Now, we shall put all these ideas together and see how we get all the answers to the fundamental questions that we raised at the beginning of the course. We shall begin this analysis in the next lecture.
