**Stability Equilibrium Points Continued**

Welcome back, last time we were discussing the autonomous systems of first order equations. And we defined orbits through a given point, positive orbits. And we studied some simple properties of these orbits. And we also stated a calculus lemma, which will be useful in analysis of some simple example, which we are going to do now. So, let me again continue with some more examples. So, in this example I would like to indicate to you the significance of the equilibrium points.

(Refer Slide Time: 01:16)

Examples (Contd.)

3.  $\dot{x} = 1 + x^2$ ; does not have equilibrium pts  
 $x^4, x^6, \dots, \sin^2 x,$

Claim: No solution is bounded

Method:  $\dot{x} \geq 1 \quad \forall t$   
Integrate w.r.t  $t \Rightarrow x(t) \geq \underline{t+C}$   
 $\Rightarrow \lim_{t \rightarrow \infty} x(t) = \infty$

NPTEL

So, I take an example, this is an example continued. This is the third example again 1 d,  $\dot{x}$  is equal to 1 plus  $x$  square. So, notice that this does not have equilibrium points. And this right hand side is 1 plus  $x$  square is always bigger than equal to 1. So, there is no particular reasoning for this 1  $x$  square, so you can put any functions. So, for example,  $x^4$ ,  $x^6$  anything and even you can put  $\sin^2 x$  etcetera. What I want is that this is a non-negative quantity, so that the right hand side does not vanish for any  $x$ .

So, I claim that no solution of this equation is bounded. You see the absence of equilibrium points says that for this particular equation, no solution is bounded. And in fact, this is more or less true in one dimension. We can see it very easily even in more dimensions, I will mention some examples that is also true. So, in one dimension it is very easy to see, so 1th is the right hand side term is does not vanish. So, for all  $x$  it has to either remain positive or negative.

So, this solution will always be increasing or decreasing, so that is the reason this solution cannot be bounded, let me try to give a different reason. In fact, I will mention some of the some 3 methods to see why the solution no solution is bounded and you can see the power of calculus, simple calculus. So, I am not writing any solution in explicit form, in-fact I do not know whether I can write. If, I take any arbitrary non-negative or positive function, I do not know that.

But, simple calculus will tell me that no solution of that equation is bounded, so method 1, so this is just calculus, we will also learn some analysis here. So, look at the right hand side  $1 + x^2$  therefore,  $\dot{x}$  is bigger than or equal to 1 for all  $t$ . So, I take any solution  $x$  of  $t$  and if that satisfy this given equation then I must have this  $\dot{x}$ . Remember  $\dot{x}$  is  $\frac{dx}{dt}$  that is always bigger than equal to 1, though we cannot differentiate an in-equality fortunately, we can integrate an in-equality.

So, integrate this in-equality with respect to  $t$ , this is calculus integrate with respect to  $t$ , so that implies  $x$  of  $t$  is bigger than or equal to  $t$  plus some constant. Now, look at this right hand side  $t + c$ , as  $t$  goes to infinity that goes to infinity. And the solution  $x$   $t$  always stays above that, so that implies, this limit  $x$   $t$  as  $t$  equals to infinity, so it is unbounded.

(Refer Slide Time: 06:19)

4.  $\ddot{x} = 1 + x^2 \rightarrow$  no equilibrium points

Method 1: Write as a system:

$$\begin{cases} \dot{x} = y \\ y = 1 + x^2 \end{cases}$$

$\Rightarrow y \geq 1 \Rightarrow y(t) \geq t + c \Rightarrow \lim_{t \rightarrow \infty} y(t) = \infty$   
 $\Rightarrow y(t) \geq 1$  for  $t \geq t_*$ , for some  $t_*$

From first equation,  $\dot{x} \geq 1$  for  $t \geq t_*$   
 $\Rightarrow x(t) \geq t + c$  for  $t \geq t_*$   
 $\Rightarrow \lim_{t \rightarrow \infty} x(t) = \infty$

So, let me just view this same idea for this second order equation. Now,  $x$  double dot is equal to 1 plus  $x$  square, again no equilibrium points. So, this no equilibrium points and again the claim is no solution is bounded even for this equation, it is a second order equation. Let me again now describe it in different ways, so method 1 again it is simple calculus. So, let me stress that point a simple calculus we are not, you can try to solve it. If you can I do not know whether an explicit solution for this equation is possible or not, but I am not interested as of now in the explicit solution.

But, just I like to show that any solution to this equation is unbounded. So, write this as a system write as a system. So, I introduce another variable  $y$ . So,  $y$  is introduced by this  $x$  dot equal to  $y$  and  $y$  dot equal to  $y$  dot will be  $x$  double dot and from the equation I get. So, this is my new variable  $y$   $x$  dot equal to  $y$  and from the given equation  $y$  dot will be 1 plus  $x$  square. And now again if you look at the previous example. Now, I use that example for this  $y$ , so that. So, this implies  $y$  dot is bigger than equal to 1 and again upon integration that implies  $y$   $t$  is bigger than equal to  $t$  plus  $c$ .

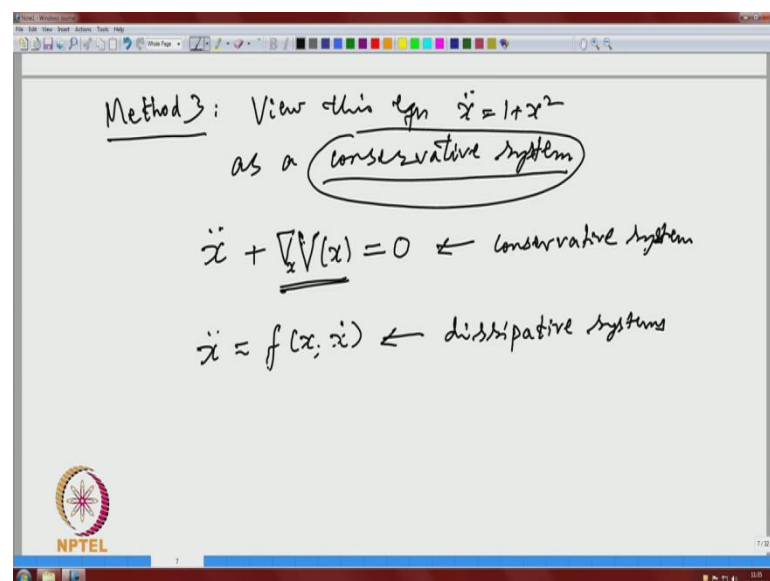

So, this clearly says that  $y$   $t$  goes to infinity, so in particular it says  $y$   $t$  is bigger than equal to 1 for  $t$ , not necessarily for all  $t$  but some  $t$  star. So, that you  $t$  star for some  $t$  star that you can calculate from this  $t$  plus  $c$  in this thing. So, you want bigger than or equal to 1. And now you go back to the first equation here and view this  $y$   $t$  is bigger than or

equal to 1. So, that implies from first equation,  $\dot{x}$  is bigger than equal to 1 for  $t$  bigger than or equal to  $t^*$ .

So, instead of now I integrate from  $t^*$  to some  $t$ , so I am only in this range and that implies again. So,  $x(t)$  is bigger than equal to now  $t$  plus some constant for  $t$  bigger than or equal to  $t^*$  and that implies limit is infinity and already this has given us limit  $y(t)$  as  $t$  goes to infinity is also infinity. So, remember  $y$  is nothing, but the first derivative of  $x$ . In this case both  $x$  and  $\dot{x}$  they go to infinity there are unbounded.

So, it is not necessary that both  $x$  and  $\dot{x}$  are unbounded in some situation it can happen that one of them will be bounded, but other certainly where at least one component will go to will be un-bounded. So, hence the orbits will be un-bounded. So, in the absence of equilibrium points, this is the point we note, so in the absence of equilibrium points, the solutions will be un-bounded. So, the orbits will be un-bounded we go to the next example.

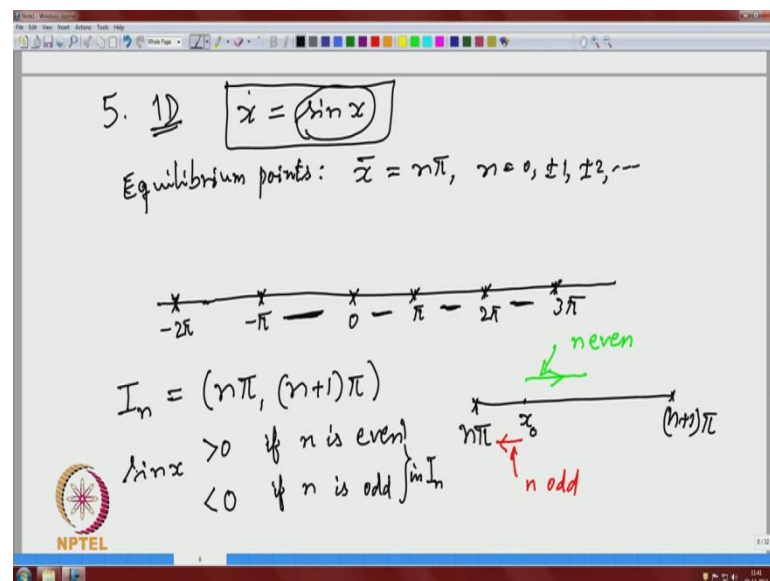

(Refer Slide Time: 11:40)

So, method 3, view this equation  $\dot{x}$  equal to 1 plus  $x$  double dot as a conservative system. We will have a detailed discussion on this conservative systems at that time. We can come back to this example and analyze using whatever methods. We derive in this conservative systems, in general a system  $x$  double dot either an equation or an equation or so this is differentiation with respect to  $x$ . So, this is this is called a conservative system. We will see in detail later, I am just introducing some terminology that is all.

And when remember here only  $x$  is involved, so it is an autonomous system, but only  $x$  is involved. So, when this term also contains  $\dot{x}$  for example suppose, I have a system like this  $x, \dot{x}$  so both, so these are called dissipative systems. So, dissipative systems are more difficult to handle than the conservative systems, so we will see little later. For example, you have seen in the discussion on problems. So, the Duffing equation and Van der Pol equations are examples of dissipative systems.

(Refer Slide Time: 14:15)

So, we will see them in more detail later; let me now go to other example the 1 dimensional cosine of pendulum equation, for this equation. So, let us write down the equilibrium points, what are the equilibrium points, equilibrium points are those at which the right hand side vanishes that is  $\sin x$ , the 0's of  $\sin x$ , these are plenty. So, this is just  $\bar{x}$  equal to  $n\pi$  all multiples of  $\pi$ , so  $n$  is an integer plus or minus 1 etcetera.

So, there are an infinite number of equilibrium points that you remember. So, let me just draw these points, so this is 0, this is  $\pi$ ,  $2\pi$  that is sufficient. So, each orbit passing through these points is just singleton, these are the orbits. So, these are equilibrium points and orbit passing through them is, any orbit suppose it starts here, it has to stay here, it has to stay here, it has to, so it cannot cross. So, we will in this case we will have an infinite number of orbits.

So, let us analyze in one particular interval. So, let us you take this let me call it  $I_n, n\pi, n\pi + \pi$  two consecutive equilibrium points. And I would like to see, how the orbit

starting in this open interval behaves you know that is our phase line analysis. So, I would like to see, I would like to start the solution somewhere here and see how it behaves. So, you let me write slightly bigger  $n\pi$ ,  $n\pi + 1\pi$  in the interval  $I_n$  and I start an orbit through this  $x$  naught,  $x$  naught is in  $I_n$ .

So, again you back to simple calculus. So, what we if you recall, what we did in other examples we would like to see, whether this solution is increasing or decreasing and that will help us in determining the direction of the orbit. So, again go back to this equation  $\dot{x}$  is equal to  $\sin x$ . So, if I can determine the sign of  $\sin x$  then that I will determine the sign of  $\dot{x}$  and that will help me in determining the direction of the orbit and now look at  $\sin x$ .

So,  $\sin x$  has different behavior so this is positive if  $n$  is even. So, that you can easily check in this interval negative  $n$  is this is in  $I_n$  this is in  $I_n$ . So, if  $n$  is even  $\sin x$  is positive and if  $n$  is odd  $\sin x$  is negative so; that means, what if  $n$  is odd  $\sin x$  is decreasing, let me just, the solution is decreasing. So, this is  $n$  odd whereas, if  $n$  is even, it is positive, so it increases. So, it just of course, this  $n$  is even you see the behavior of solution is very much dependent on whether this integer is positive or negative that is and you will use calculus lemma in either case, let me just...

(Refer Slide Time: 19:53)

Use Calculus Lemma: If  $n$  is odd,  $\lim_{t \rightarrow \infty} x(t) = n\pi$   
If  $n$  is even,  $\lim_{t \rightarrow \infty} x(t) = (n+1)\pi$

Exercise Let  $x_0 = n\pi + \alpha$ ,  $0 < \alpha < \pi$ . Show that the solution  $x(t)$  of  $\dot{x} = \sin x$ , with  $x(0) = x_0$  is given by

$$x(t) = \begin{cases} n\pi + 2 \tan^{-1}(Ce^{-t}) & \text{if } n \text{ is odd} \\ n\pi + 2 \tan^{-1}(Ce^t) & \text{if } n \text{ is even} \end{cases}$$

where  $\alpha = 2 \tan^{-1}(C)$  ( $\tan^{-1}: \mathbb{R} \rightarrow (-\pi/2, \pi/2)$ )

So, use calculus lemma, this is an important result from. So, if  $n$  is odd look at here it is decreasing, so this is the situation  $n$  odd. So, it is decreasing and bounded below by  $n\pi$ .

So, it cannot cross  $n\pi$ , because that is the 2 orbits cannot cross that is the, so simple one of the simple results of orbits, properties of the orbits, so we have. So, the limit exists  $\lim_{t \rightarrow \infty} x(t)$  it exists, it exists and again one of the properties of the orbits, when that solution has a limit it has to be an equilibrium point and in this situation, the only possibility is that it goes to  $n\pi$ .

Because there are no other equilibrium points between  $n\pi$  and  $x_0$ , the nearest equilibrium point to  $x_0$  is this  $n\pi$  and whereas, if  $n$  is even its increasing. And now it is bounded above by  $n + 1\pi$ , so it has to go to  $n + 1\pi$ . And important thing you should notice here is I do not have any explicit form of the solution, just based on the properties of orbits and simple properties of orbits and this calculus lemma, I am able to derive so that means, a solution starts in this interval  $I_n$ .

So, it has these properties, I do not have any knowledge of the explicit form of the solution. But, I have this qualitative behavior and that is the power of this qualitative theory, so you should realize that. So, without having an explicit knowledge of the solution we are able to derive it is for example, these limits we are able to do that. So, in this case you also have an explicit form of the solution, let me just take that as an exercise.

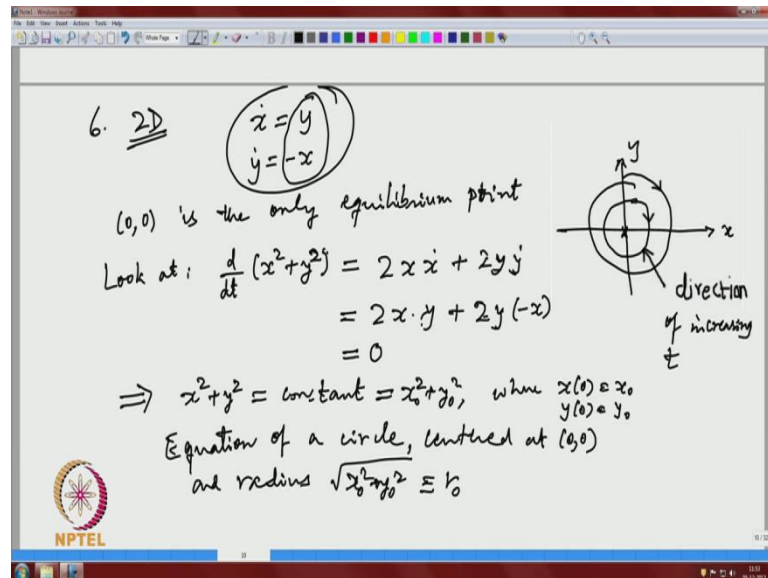

So, it is very simple equation  $\dot{x} = \sin x$  and you might try using the separation of variables to derive an explicit formula for this solution you can do it, but just like to caution you. So, when you try to do this thing, you get in to this tan function an implicit relation, as  $\tan x = \text{something}$  and then a task is to invert that tan and tan is a multi-valued function. So, you should exercise caution, when you are trying to invert that tan, so let me just see that.

So, let  $x_0$  equal to, since it is in  $I_n$ , so I can always write that as  $\alpha$ . So,  $0 < \alpha < \pi$  so; that means,  $x_0$  is in that interval open interval  $I_n$ , show that the solution, it is a good exercise  $x(t)$  of  $\dot{x} = \sin x$  with, so I give the initial. So, I take  $x(0) = 0$ ,  $x_0$  is given by and we have already observed the different behavior of the solution depending on whether  $n$  is odd or even. So, the same thing we can expect in the form of solution also.

So, just let me write that thing,  $x(t)$  is equal to  $n\pi + 2 \tan^{-1} e^{-t}$  if  $n$  is odd,  $n\pi + 2 \tan^{-1} e^{-t}$  if  $n$  is even, so this is for all  $t$ . So, what is

this  $c$ , where  $\alpha$  is equal to  $2 \tan^{-1} c$ . So, you have used this  $\tan^{-1}$  many times from your college plus 2 level, let me recall. So, again this  $\tan^{-1}$  is a function from  $\mathbb{R}$  to  $[-\frac{\pi}{2}, \frac{\pi}{2}]$  this is one or two just a recall, so it is a very good exercise. And as and when we develop more concepts, we will again come back to these examples again and again.

(Refer Slide Time: 26:56)

So, let me now mention one 2 D example, so we have already considered it many times, so here there are two functions. Let me give the  $x$  and  $y$ , so  $y$  dot equal to minus  $x$ , so it is a 2 D system, very simple system. So, here  $0, 0$  is the only equilibrium, so I want the right hand side to be 0 here. So, the first equation gives me  $y$  equal to 0 and second equation gives me  $x$  equal to 0. So, that is the only equilibrium point here and of course, you can explicitly solve this thing, but without explicitly solving, let us try to analyze the orbits again.

So, look at  $\frac{d}{dt}$  of  $x^2 + y^2$ , this is a standard example, we are again will be seeing this again and again, so if  $x$  and  $y$  are solutions of this given system. Let me calculate this  $\frac{d}{dt}$  of  $x^2 + y^2$ . So, this is just  $2x\dot{x} + 2y\dot{y}$  and let me just substitute for  $\dot{x}$  and  $\dot{y}$  from the given equation. So, this is just  $y + 2y\dot{y}$  is minus  $x$  and you see that this is 0, so  $2xy - 2xy$  that is 0, so that tells you that this implies.

So, this is true for all  $t$ , so  $x^2 + y^2$  is just a constant, so initially whatever you give  $x(0)$  equal to  $x_0$  and  $y(0)$  equal to  $y_0$ . So, then I get  $x_0^2 + y_0^2$ , where  $x_0$  is  $x_0$  and  $y_0$  is  $y_0$ . So, the orbit, satisfy this simple equation and this is equation of circle centered at the origin and radius square root of  $x_0^2 + y_0^2$ . So, let me call this as  $r_0$ , it is very easy to draw these orbits.

If I take  $x(0)$  equal to  $y(0)$  equal to 0, I get the equilibrium point namely  $x=0, y=0$ . So, this is  $x$  axis, this is  $y$  axis and if one of them is non-zero then  $r_0$  is positive, so you just get. So, these are all the orbits for this simple equation there the orbits. So, again we have to indicate the direction in which  $t$  is increasing and I will just mention that, so this will be the direction.

So, if you change again the signs, here it will be this will be in counter clockwise, if you change the signs here it will be counter clockwise, so this is direction of, so remember that. So, whenever we draw orbits, we have to indicate in which direction increase  $t$  the values of  $t$  are increasing, so that we have to mention. So, we will come back to these examples again as and when we introduce new concepts.

(Refer Slide Time: 31:55)

So, next we are going to introduce the concept of stability. So, let me begin with a simple game experiment, whatever you call it and all of us at some stage of our childhood either we have done this thing or we have seen it again this simple thing. So, you take a bowl, you place it in this way and you also place it in inverted way and place a marble here and

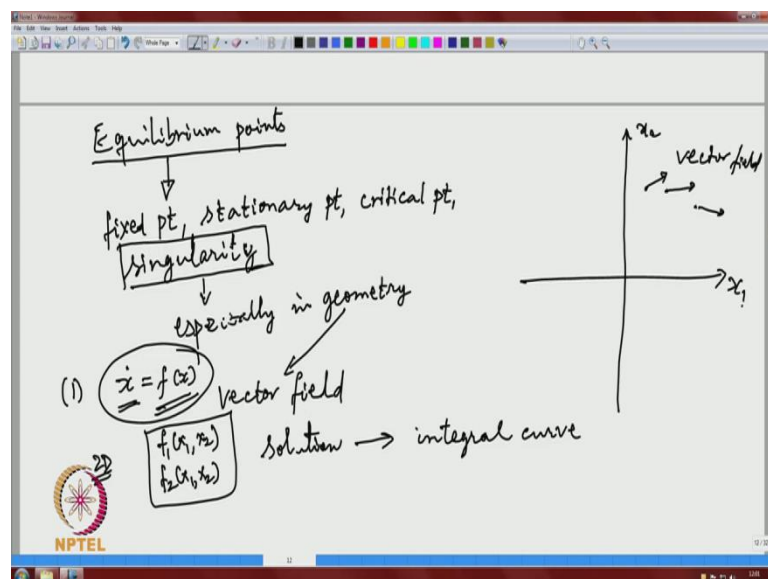

carefully place this marble here. In the first case, if I move this marble little bit this way, this way it will have few oscillations and come back to the original position, so this is the example of stability.

And same thing if I want to do for this marble and if I push either this side or that side it will just fall off, so this is unstable, so this is stable and that is what. So, this is equilibrium position and this is also an equilibrium position. But, this is unstable and this is stable, so we are going to introduce the concept of stability of an equilibrium point there are more general at this point. Let me make some remarks there are more general concepts of stability of a solution, orbital stability and even structural stability they are more advanced topics.

So, for this introductory course, we want to make even this introductory course little advanced by introducing some additional topics, than the usual topics that are covered in m s c syllabus and. In fact, this qualitative theory is one part of such an advance thing. So, in this course we just introduce this concept of stability of an equilibrium point, these are special solutions as we already learnt.

So, we concentrate only the stability or instability of equilibrium points, in this course. And for more advanced things once you learn this concept, you can always refer to the more advanced text, which are listed in the references and learn more about them. So, before going further let me just a remark again, we will be talking now more.

(Refer Slide Time: 35:36)

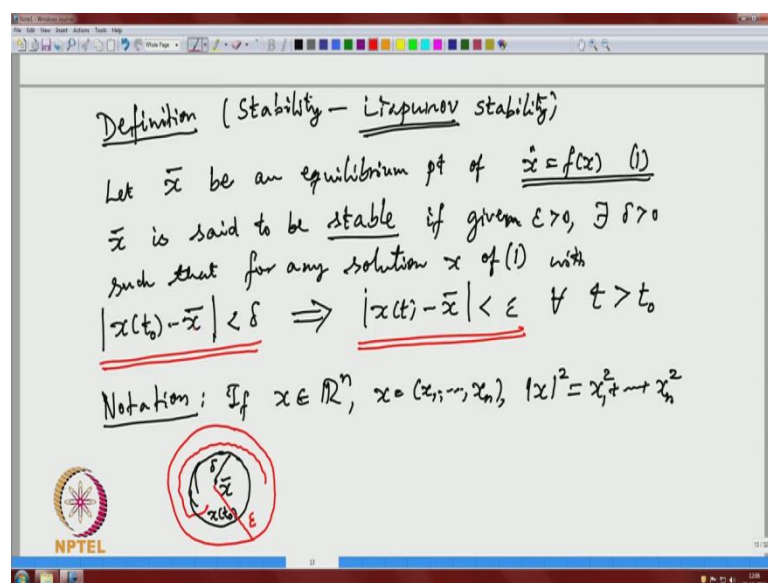

So, this equilibrium points, let me just spend few minutes. So, just like the synonyms for orbits or trajectories and paths there are many synonyms for equilibrium points also and some of them are fixed point, point I will write  $p$  stationary point critical point. So, different books might give different terminology etc. So, you will find many more and one terminology that is used frequently in geometry is singularity. Let me just spend few minutes, they call also these equilibrium points as singularities.

So, this is especially in geometry differential geometry. So, talking about geometry the system 1, so which we start at this  $\dot{x} = f(x)$ . So, we will just call it because all our analysis is about that equation. So, in geometry this is called a vector field and impartibly this right hand side, especially right hand side. For example, in 2 D case, we have  $f_1$  of  $x_1, x_2$  and  $f_2$  of  $x_1, x_2$ , so these are given functions and, so let me just.

So, at every point a direction is given, so this is you take a point here, it is given here and given. So, this is the vector field and then given this vector field, one would like to construct a curve having this given vector field as tangent. So, this geometrical interpreted a tangent and in this terminology in geometry, solution is called or solution curve is called integral curve integral, so that is geometry.

So, regarding this terminology singularity, so when  $f_1$  and  $f_2$  are both not 0. So, at least one of them is not 0. So, this  $f_1, f_2$  defines a unique direction as you can see here. But if both are 0, then there is no direction, direction is suddenly lost and that is perhaps the reason why in geometry they refer to this equilibrium points as singularities. But whereas, since we are having the notion of dynamical system. So, this equilibrium points are stationary points or even critical points are appropriate terminology, when you view this equation 1 as a dynamical system, so with this simple remark.

(Refer Slide Time: 40:07)

So, let me now just introduce the definition of stability, so define a Russian mathematician, Lyapunov was the one who contributed a lot to this theory of stability. In fact, what we are going to study is this Lyapunov stability. So, everything is attributed to Lyapunov even if I do not write that. So, whatever we are covering in this lecture and perhaps next lecture. So, let  $\bar{x}$  be an equilibrium point of this  $\dot{x} = f(x)$ , so that is our autonomous system, so again I call it 1, so that you always remember.

So,  $\bar{x}$  is said to be stable Lyapunov stable, so this definition is more closer to the usual continuity, definition of a function at a point. So, with usual epsilon and delta let me state it and then we see the geometry if given epsilon positive there exists delta positive, such that for any solution  $x$  of 1 with  $|x(t_0) - \bar{x}| < \delta$ . So, new notation you see I will just introduce that thing, less than delta implies  $|x(t) - \bar{x}| < \epsilon$  for all  $t > t_0$ , so this notation. So, this is just the Euclidean distance in  $\mathbb{R}^n$ , so notation.

So, if  $x$  is in  $\mathbb{R}^n$  with components  $x_1, x_2, \dots, x_n$ , so denote by this is actually a norm  $|x| = \sqrt{x_1^2 + x_2^2 + \dots + x_n^2}$  and this is just square root of that. So, what does the definition say, so here is  $\bar{x}$ , so at some initial time  $t_0$  if the solution, so this just. So,  $|x(t_0) - \bar{x}| < \delta$  is this distance is delta and the requirement is that the solution  $x(t)$ . So,  $x(t)$  is here and then the orbit, the solution will not go beyond this, that is what the second condition says.

So, once the solution at time  $t_0$  is within a delta distance from  $\bar{x}$  then for all future times. So, this is all future times  $t$  bigger than  $t_0$  it will stay within an epsilon distance from  $\bar{x}$ , so important thing that  $\bar{x}$ . So, we are discussing the stability of this given  $\bar{x}$ .

(Refer Slide Time: 45:27)

Otherwise,  $\bar{x}$  is said to be unstable

$\downarrow$

$\exists \epsilon > 0$  s.t.  $\forall \delta > 0$ , & a solution  $x$  of (1)  
 with  $|x(t_0) - \bar{x}| < \delta$ ,  $\Rightarrow |x(\tilde{t}) - \bar{x}| > \epsilon$  for some  $\tilde{t} > t_0$

$x(t_0) \neq \bar{x}$

NPTEL

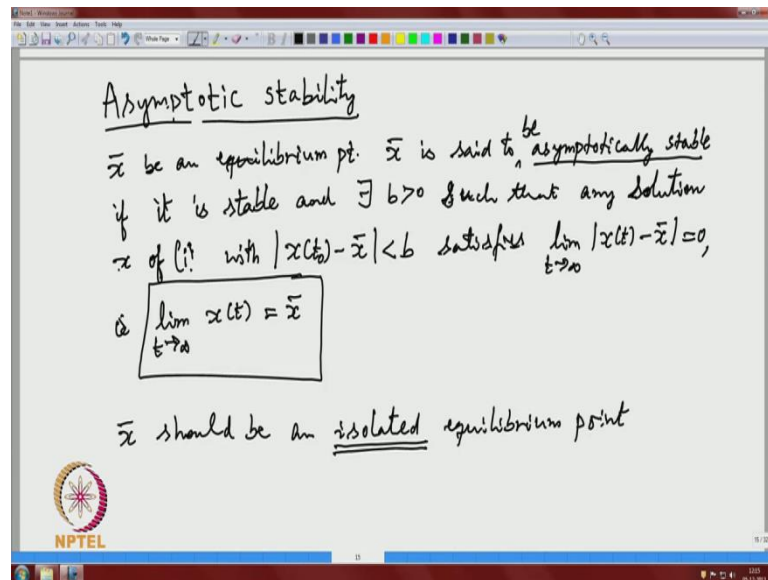

So, otherwise if that is not satisfied, otherwise  $\bar{x}$  is said to be unstable this otherwise you just write the negation of the statement, carefully write it. So, here if you go back again if, you have to write the negation of this thing, there exists some delta. So, let me just mention that, that is important, so otherwise so that means, so there exists an epsilon positive such that, for all delta positive and a solution  $x$  of 1 with  $x(t_0) - \bar{x}$  less than delta.

So, likewise  $x(t_0) - \bar{x}$  will be bigger than epsilon for some  $\tilde{t}$  bigger than  $t_0$  sometimes negations are difficult to write. But, carefully see the logic and this what happens, now no matter how close I start, so that a solution, there is a later a time and the solution leave that epsilon ball, so that what happens, so this. So, there is an epsilon ball here, sorry this is not, so  $\bar{x}$  is there and this, so that is some epsilon. So, no matter how close I start, this is  $x(t_0)$  and this is delta any delta that is important, any delta.

So, you can come as close as possible, except that you should not be at  $\bar{x}$  there then that is an equilibrium solution. So, you will stay there for all times, so that I have to mention, so  $x(t_0)$  and  $x(t_0) \neq \bar{x}$ . So, that is important we are not then and

then if you start and eventually that fellow will come out at  $t^*$ , so this is  $\tilde{x}$ , he has come out of that  $\epsilon$  bar that is what it says. So, in the remaining few minutes, so let me just tell what I am going to do in the next class.

(Refer Slide Time: 49:42)

So, next we are going to introduce the concept of asymptotic stability, again of an equilibrium point, so it is slightly more than stability, again let me just. So, let  $\bar{x}$  be an equilibrium point, let me say it in few words and I will continue in the next class. So,  $\bar{x}$  is said to be asymptotically stable, if it is stable, so that is the first requirement. So, it has to be stable slightly more than that, then and there exists  $b$  positive such that any solution  $x$  of 1 with  $|x(t_0) - \bar{x}| < b$ , satisfies  $\lim_{t \rightarrow \infty} |x(t) - \bar{x}| = 0$ .

So, this is same as saying that  $\lim_{t \rightarrow \infty} x(t) = \bar{x}$ , so in order to even have some good meaning for this definition, an additional thing has to be noticed, so that this  $\bar{x}$  should be an isolated  $\bar{x}$  should be this concept, I will introduce that it should be an isolated equilibrium otherwise. What we have stated is technically not correct, because if there are more equilibrium points near  $\bar{x}$ , then we cannot even have these definitions. So, I will say, what this isolated equilibrium point is, then the definitions make very good sense and then we will have some more examples and we will proceed.

Thank you.
