Linear Algebra Continued

Welcome back. So, yesterday we were discussing about similarity matrix and let me begin with the advantage of this similarity matrix. So, this is our, so a is an introduced notation yesterday.

(Refer Slide Time: 00:43)

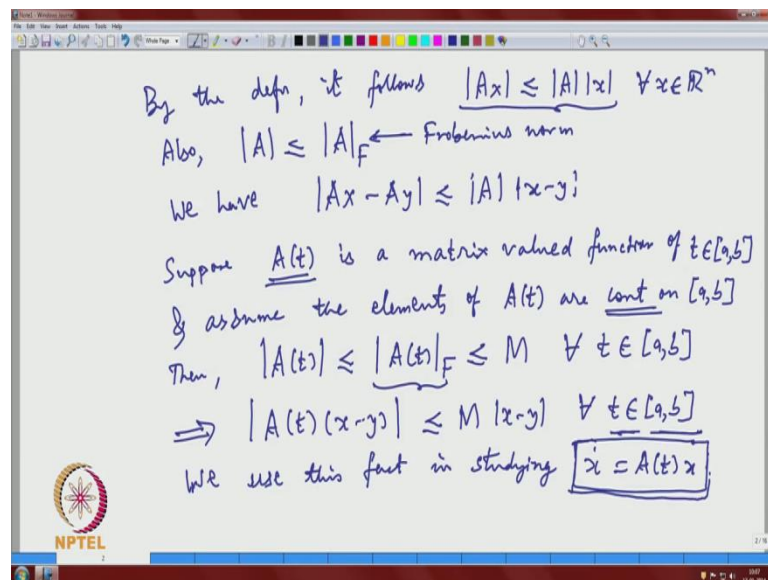

So, this is an m by N real matrix ok we call a is similar to b , so suppose there exists non-singular C belonging to $m \times N$ r such that C inverse a C equal to b . So, this is we say that a and b are similar. So, we are aiming at finding suitable such that this B is either diagonal are in the worst scenario an upper triangular matrix we will come to this little later and we also saw that, so this implies C inverse E a C equal to E to the b . So, the exponentials of a and B are also similar in the context of a d , so let us consider this x dot equal to a x suppose this is the given system and remove that the general solution it is given by E to the t a and x naught x naught is an arbitrary vector in $r \times m$ and now through similarity transformation we transfer this given system into y dot equal to B y and similarly y is t is given by E to the t B sum y naught and when B is this simple either diagonal or upper triangular this is very easily computed.

Not only that, we can easily analyse the qualitative behaviour of this y and how x and y are connected it is very easy, so you just you put y is equal to C inverse x and. So, this y naught will be just C inverse x naught and once you know y , so it is easily we can also analyse x since x is $C y$, so that is the advantage.

So, that is why this all effort is being done to find the suitable non-singular C such that this C inverse is equal to B and B is quite simple. So, that we can compute the exponential of $E B$ very easily and then we analyse the solution of this ready system and then we get information about the original system that is the advantage ok. So, let us now begin with this thing, so before going to that thing, so just let me again make a few remarks.

(Refer Slide Time: 04:45)

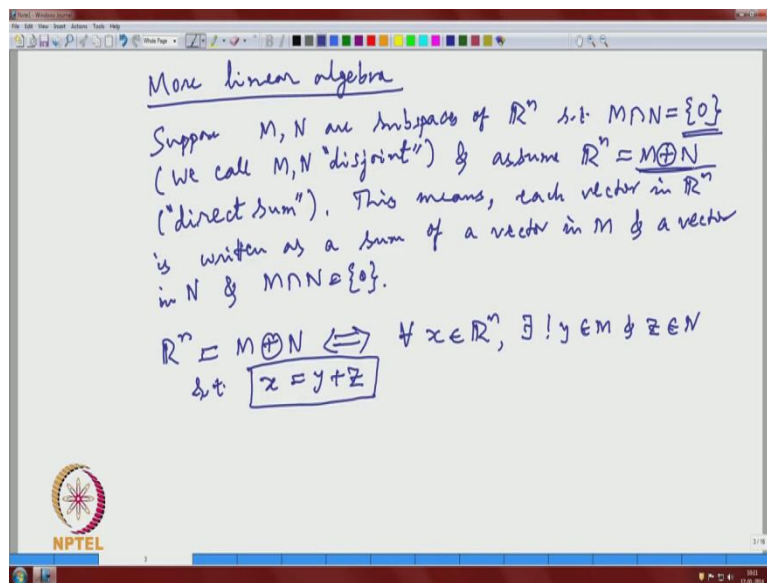

So, by the definition of the norm it follow that norm of a x is less than and equal to norm a norm x for all x in \mathbb{R}^m we also, saw that also we saw this a is less than or equal to this frobenius norm ok, so this is frobenius norm and from this if I replace x by x minus y and by linearity of a , so we have $a x$ minus $a y$ less than or equal to norm $E x$ minus y and that proves this function x going to $a x$ is Lipchitz continuous.

More is true. So, suppose $A t$ is a mat matrix valued function of t in sum interval, so that means, for each t in $A b A t$ is in $m N r$ and suppose and assume the elements of $A t$ are continuous on $a b$ and then, this for each t I have this thing and since this frobenius norm is sum of all squares of the elements of $A t$ and since I am assuming they are all

continuous, so this is just a some let me put m for all t a using continuity of the elements of A t ok.

So, this implies, so we have this useful inequality. So, less than equal to m x minus y for all t in A b, so that means, this matrix the x going to A t x is uniformly Lipchitz in this interval and this is we use this fact in studying the linear system x dot equal to A t x and because of this global existence the solutions exist in any interval where A t is continuous.

(Refer Slide Time: 09:07)

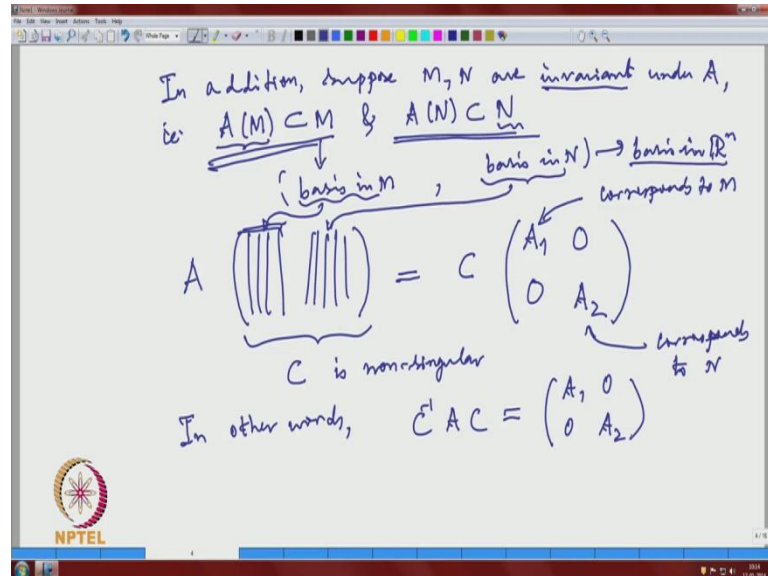

So, with this little remark, so let us again go back to linear algebra more linear algebra as we have said yesterday, this is not a course on linear algebra , so I am just recalling certain facts that are used in our study of differential equations. So, suppose m and N are subspaces of r N such that, so since they are subspaces 0 element is always there and I just want their intersection to be just 0 we concept such spaces m N disjoint. So, though the intersection is not empty, but it is the trivial subspace namely the 0 subspace we still call it disjoint and assume r N is m plus N ok.

Let me explain that little bit. So, this is called direct sum of m N this means each vector in r N is written as a sum of a vector in m and a vector in N and this condition m N are discharged ok. So, we can easily check that r N is equal to m plus N m direct sum m if and only if for all x in r N there exists unique y in m and z in N such that a x equal to y

plus z ok, that should happen and this is easily extendable to any finite number of subspaces and that is what we are going to do ok.

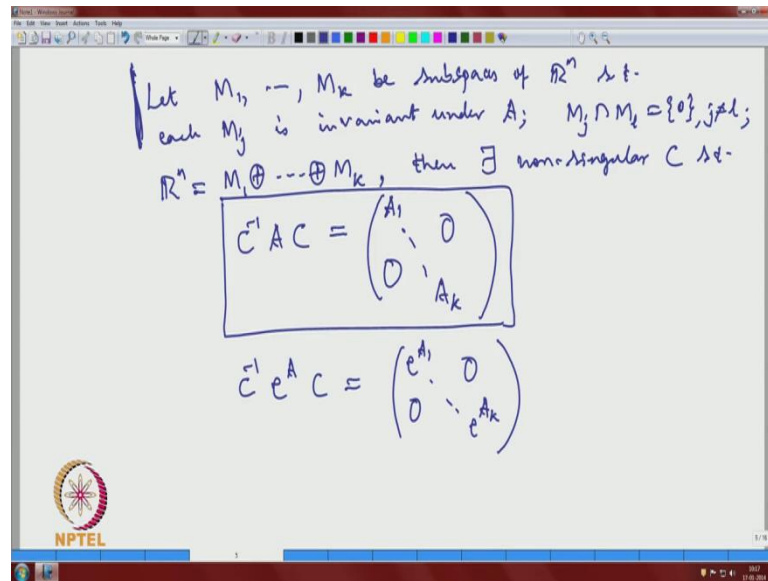

(Refer Slide Time: 12:37)

So, in addition suppose m, N are invariant under a , so remember a is given matrix N by N matrix, so that is again definition a m , so you act a on every element of m and again that should be in m and similarly for n . So, this means this means you act a on every element of m and again the result should be again back in m in this situation, suppose we choose a basis in m and a basis in N and if you put together that will be a , so I will I am just try to this and this will form a basis in r m now you take those basis elements and form this matrix C ok, so this is C and these are you put the basis elements of m here and then you put basis elements here ok and then you add a . So, since these are all basis vectors C is non-singular and by this suggestion that m and N are invariant under a you can easily check that this C is here $A_1 \ A_2$, so this is sub matrix, so this is corresponds to m and this correspond to n because if I act a on this basis elements which are in m and the result is again they are back in m , so each action is again a linear combination of vector of these things and that is expressed like that.

So, in other words, so if you have two subspaces invariant under m and whose dimension is r m then the matrix with respect to that basis decomposition to a block matrix. So, in other words what we have is $C^{-1} A C$ is $A_1 \ 0 \ 0 \ A_2$ and this is easily extendable to make finely many subspaces.

(Refer Slide Time: 16:04)

So, let me just state that thing, so let M_1, \dots, M_k be subspaces of \mathbb{R}^n such that each M_j is invariant under A that is 1 condition and I have $M_j \cap M_l = \{0\}$ different from 1, so they are mutually disjoint and the third condition, so \mathbb{R}^n is direct sum of M_k with these conditions then there exists non-singular C such that $C^{-1} A C = A_1 \oplus \dots \oplus A_k$.

So, in other words in such a situation we can find a similar matrix which is a block diagonal matrix satisfying this condition, so this is important in this immediately we see that $C^{-1} e^A C = e^{A_1} \oplus \dots \oplus e^{A_k}$ etcetera e^A this we saw yesterday ok.

Once the matrix is block diagonal it is very easily computed and now we proceed to find some special subspaces of \mathbb{R}^n which are related to A and we satisfy this hypothesis of this thing, so that we have a similar block matrix which is similar to A . So, that is our next aim.

(Refer Slide Time: 18:47)

Spectrum of A , $\text{sp}(A) \equiv$ set of all eigenvalues of A

$$\text{sp}(A) = \left\{ \underbrace{\lambda_1, \dots, \lambda_r}_{\text{real}}, \underbrace{\mu_1, \dots, \mu_s}_{\text{non-real}}, \underbrace{\bar{\mu}_1, \dots, \bar{\mu}_s}_{\text{non-real}} \right\}$$

$\therefore r + 2s = n =$ order of A
 $=$ degree of the char. polynomial

Let $\lambda \in \text{sp}(A) \cap \mathbb{R}$. Let k be the algebraic multiplicity of λ ; this is the multiplicity of λ as a root of the characteristic polynomial.

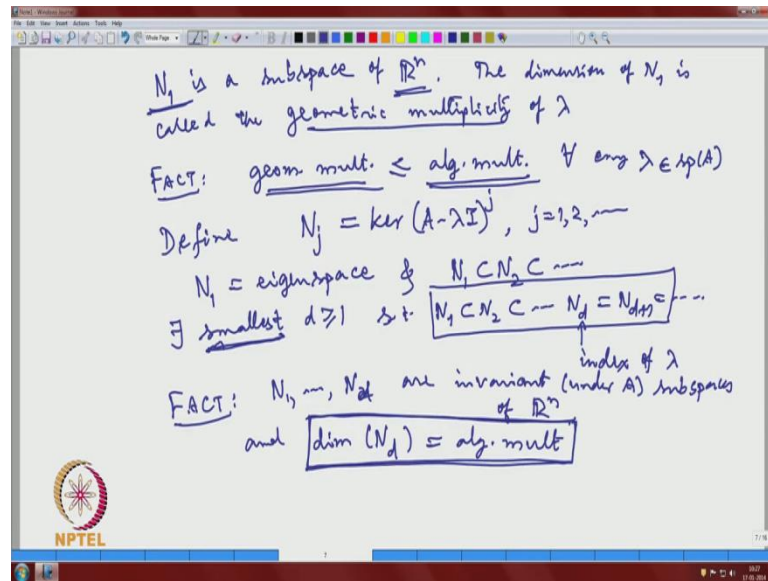

Let $N_\lambda = \ker(A - \lambda I) \leftarrow$ null space or kernel of $A - \lambda I$
 \uparrow eigenspace of A w.r.t. λ

So, yesterday I introduced the concept of spectrum of a, so this is just a spectrum of a, so denoted by sp of a, so this is set of all 8 values of a though a is a real matrix an Eigen value of a could be real complex ok.

So, let us split this into two parts, so let us $\lambda_1 \lambda_2 \dots \lambda_r$, so these are real Eigen values counted with multiplicity and then this we have $\mu_1 \mu_2 \dots \mu_s$, so these are nontrivial and since the characteristic problem well has real coefficients we also have this $\mu_1 \bar{\mu}_1 \dots \mu_s \bar{\mu}_s$ also Eigen values of a ok, so these are also non, so they always occur in pair, so the total number because we are counting multiplicity, so therefore, we have r plus $2s$ is equal to n , so this is the order of a and this is also the degree of the characteristic polynomial right, so now just pick, so let λ belongs to spectrum of a also real. So, complex is similar.

So, let k be the algebraic multiplicity of λ , so this is the multiplicity of λ as a root of the characteristic polynomial that is right, so there is another notion called geometric multiplicity, so for that we have to introduce a subspace, so let a $N_\lambda = \ker(A - \lambda I)$ ok. So, this is the null space of null space or kernel of this $A - \lambda I$ ok. So, this is referred as Eigen space of a corresponding to λ .

(Refer Slide Time: 23:06)

So, if lambda is an Eigen value we just form this and this is a subspace of, so N_1 is a subspace of \mathbb{R}^n , so in case of complex Eigen value we take the real and imaginary parts of the Eigen vector and we still get a subspace of \mathbb{R}^n that is important that you keep in mind. So, the dimension as a subspace it has a dimension of N_1 is called the geometric multiplicity of lambda.

So, let me just take a fact that geometric multiplicity is always less than or equal to algebraic multiplicity and the difference is referred to as the difference we refer to as deficiency of lambda for any lambda, so that is always true lambda in spectrum. So, the good case is when geometric multiplicity is algebraic equal to algebraic multiplicity then we will have sufficient number of Eigen vectors spanning this subspace N_1 and a difficult part is when this is strict in equality ok.

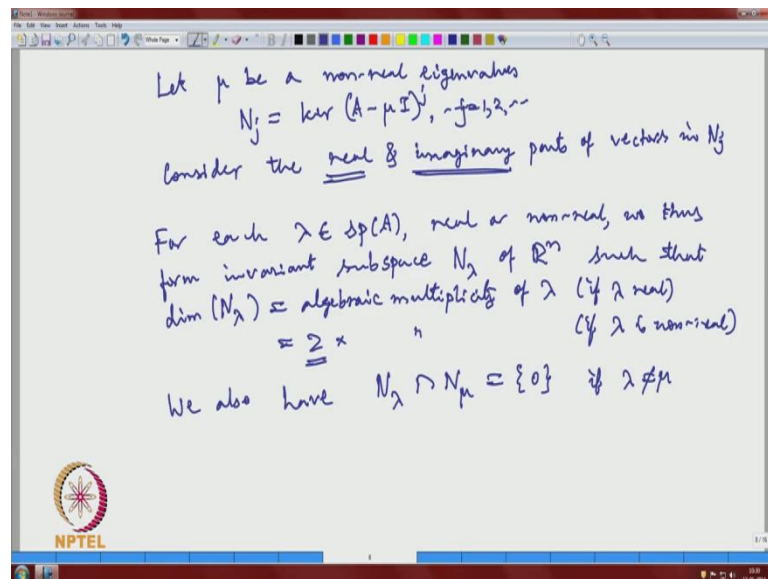

So, in that case what we do is, so now define in general, so define N_j kernel of $A - \lambda I$ to the power of j , so you do it j equal to 1 to etcetera, so N_1 is the Eigen space that we have defined and we have this j its very easily checked that this is ascending chain of subspaces and since we are in a finite dimension this chain cannot continue for long. So, there exists smallest d bigger than equal to 1 such that $N_1 \subset N_2 \subset \dots \subset N_d = N_{d+1} = \dots$ after which they are equal.

So, there are no more additions of new nonzero vectors ok, so this is smallest it has a name and this is called index of lambda. So, everything is we have fixed a real Eigen

value λ and we are just discussing about that, so it again 1 more fact, so these are all subspaces N_1, N_2, \dots, N_d are invariant under A , so let me not stress that again and again, so that is invariant subspaces of \mathbb{R}^n and more importantly and dimension of N_d is equal to algebraic multiplicity.

So, when geometric multiplicity of an Eigen value is strictly less than the algebraic multiplicity you have to go for some more linearly independent vectors in order to get the full dimension namely its algebraic you want to reach the algebraic multiplicity and this is the way 1 reaches that day ok.

(Refer Slide Time: 28:29)

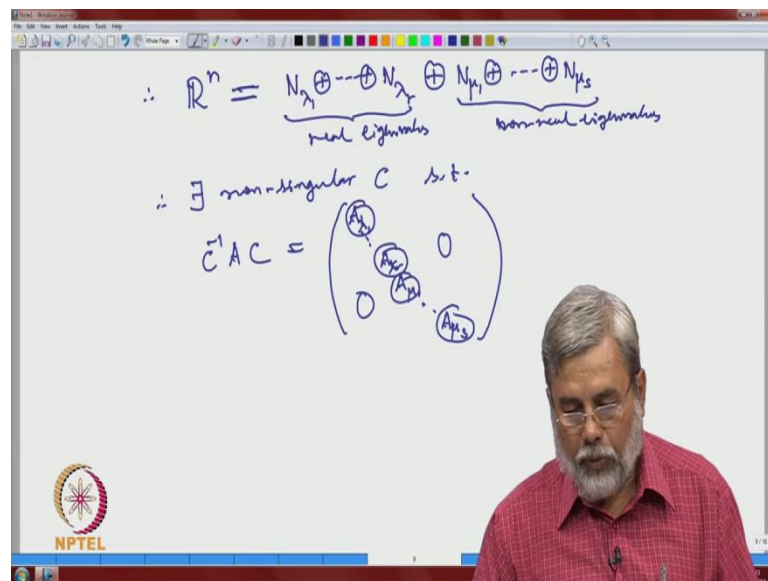

So, let μ be a nontrivial Eigen value and again you form the same thing there and there is this 1 there is no problem kernel of $A - \mu I$ N_1 equal to 1 to N and it will have some index.

Now, you just consider the real and the imaginary parts of vectors in these N_j 's that is all you have to do, because remember we want to find only a basis for \mathbb{R}^n , so we want only the real vectors and when there are complex Eigen vectors you take the real and imaginary part they are not Eigen vectors, but they are linearly independent as we saw yesterday and that will do our job, so in this way, so let me now just put this together, so for each λ in this spectrum of A of a real or non-real it does not matter we thus form invariant subspace.

So, let me call it N_λ of r_λ N that is important this subspace is $r_\lambda N$ such that dimension of N_λ is algebraic multiplicity of λ if λ is real otherwise, it is two times algebraic multiplicity if λ is non real because that count has to be proper because when λ is non real $\bar{\lambda}$ is also an Eigen value, so it has to be counted twice. So, that is why this twice and they are all invariant under A and by very choice, so you also have that $N_\lambda \cap N_{\bar{\lambda}}$ is just $\{0\}$ if λ is that is by very construction you see that ok.

(Refer Slide Time: 32:07)

So, therefore, so $r_\lambda N$ is written as, so let me just write $\lambda_1, \lambda_2, \dots, \lambda_r$, so these corresponds to real Eigen values and then I have $N_{\mu_1}, \dots, N_{\mu_s}$ ok. So, I am not writing the $\bar{\mu}_1, \dots, \bar{\mu}_s$ because they are already included here. So, these corresponds to real Eigen values and this correspond to non-real Eigen values and these dimensions perfectly match and that is why the we have this inequality and now you just give the fact we already stated since all these are invariant.

So, these subspaces are invariant, so therefore there exists a non-singular C such that $C^{-1}AC$ is now $A_1, A_2, \dots, A_r, \mu_1, \mu_2, \dots, \mu_s$ and the next task is to find a suitable basis in each of these subspaces, so that this block matrices have a very simple structure that what we are going to do next time next with.

(Refer Slide Time: 34:30)

Illustrate this by a case: How to choose a specific basis in N_d ?

Suppose λ is a real eigenvalue, of alg. mult = 4
geom. mult = 2

$$\begin{array}{ccc} N_1 & \subset & N_2 & \subset & N_3 \\ \downarrow & & \downarrow & & \downarrow \\ \dim=2 & & \dim=3 & & \dim=4 \end{array}$$

Choose $x \in N_3$ s.t. $x \notin N_2$

Check $x, \underbrace{(A-\lambda I)x}_{N_2}, \underbrace{(A-\lambda I)^2 x}_{N_1}$ are lin. indep.

Choose $u^{(1)} \in N_1$ which is linearly indep. of $u^{(2)}$

So, instead of doing for a general t , so let me just illustrate by a case how to do that illustrate this by a case. So, how to choose a specific basis in N_d . So, suppose λ is a real Eigen value of algebraic multiplicity four and geometric multiplicity two, so I have $N_1 \subset N_2 \subset N_3$ say and this dimension is 2 dimension is 3 and this dimension is 4, suppose I have this situation there are other possibilities say let us take 1 such possibility and now I would like to construct a basis where A is simplified to an upper triangular matrix ok.

So, choose x in N_3 such that x is not in N_2 this is possible because the dimension is 3 and this is dimension 4, so there is at least one non 0 vector which is in N_3 which is not in N_2 that is fine now you form this $x, (A-\lambda I)x, (A-\lambda I)^2 x$, so this is in N_2 by very definition and this vector is in N_1 and these are all non-zero. In fact, these are linearly independent check that are linearly independent and now this is a non-zero vector in N_1 , but dimension of N_1 is 2, so choose. So, let me call it $u^{(1)}$ in N_1 which is linearly independent of, so let me put some name, so this let me call this as $u^{(2)}$ and this $u^{(3)}$ and this $u^{(4)}$, if you change the order the matrix will change, so that is that is what we will see now ok.

(Refer Slide Time: 38:41)

$$A \begin{pmatrix} u^{(1)} & u^{(2)} & u^{(3)} & u^{(4)} \end{pmatrix} = \begin{pmatrix} \lambda u^{(1)} & \lambda u^{(2)} & \lambda u^{(3)} + u^{(2)} & \lambda u^{(4)} + u^{(3)} \end{pmatrix}$$

$$= \begin{pmatrix} u^{(1)} & u^{(2)} & u^{(3)} & u^{(4)} \end{pmatrix} \begin{pmatrix} \lambda & 0 & 0 & 0 \\ 0 & \lambda & 1 & 0 \\ 0 & 0 & \lambda & 1 \\ 0 & 0 & 0 & \lambda \end{pmatrix}$$

In general,
 # of Jordan blocks
 = geom mult.

Jordan blocks

If $\mu = a+ib$, $b \neq 0$,
 Jordan blocks corresponding
 to μ are of the form

$$\begin{pmatrix} B_2 & I_2 & 0 & \dots \\ 0 & B_2 & I_2 & \\ \dots & & & I_2 \\ & & & B_2 \end{pmatrix}$$

$$B_2 = \begin{pmatrix} a & b \\ -b & a \end{pmatrix}$$

$$I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

And now you add this u_1 on these vectors $u_1 u_2 u_3 u_4$ and u_1 is in N_1 , so this is just becomes λu_1 and u_2 is also in N_1 , so that becomes just λu_2 , but this is not in this u_3 is in N_2 , so if you work it out you would see that λu_3 plus u_2 and similarly you get λu_4 plus u_3 , so let me write this in the same form $u_1 u_2 u_3 u_4$ and now I write this matrix $\lambda \ 0 \ 0 \ 0 \ 0 \ \lambda \ 0 \ 0 \ 0 \ 1 \ \lambda \ 0 \ 0 \ 0 \ 1 \ \lambda$ so its very easy to check that is what we get just writing this thing and we see significantly here there is 1 block here and another block here see these are referred to as Jordan blocks.

So, in general in general the number of Jordan blocks corresponding to an Eigen value is equal to geometric multiplicity of that particular Eigen value. So, in this case we have the geometric multiplicity 2. So, we get 2 blocks ok.

And if μ is non-real, so just a plus $i B b$ non-zero the Jordan blocks are bit complicated because the Eigen vectors are complex. So, we have to take only real part and a imaginary part the Jordan blocks corresponding to μ are of the form. So, remember they always appear in pairs, so here also we get 2 by 2 blocks, so let me write just $B \ 2 \ I \ 0$ $B \ 2 \ I \ 2$ let me write etcetera. So, just diagonal blocks, so $B \ 2$ is 2 by 2 matrix this $A \ B$ minus $B \ a$ and $I \ 2$ is just $1 \ 0 \ 0$ the identity 2 by 2. So, here in case of real thing we have just scalars on the diagonal, but in the complex case you have this 2 by 2 blocks. So, this is the only difference.

(Refer Slide Time: 43:14)

Summarize Given $A \in M_n(\mathbb{R})$, \exists a non-singular C

s.t. $C^{-1}AC = \begin{pmatrix} J_1 & & 0 \\ & \ddots & \\ 0 & & J_k \end{pmatrix}$

where each J_i is a Jordan block corresponding to an eigenvalue of A

If the eigenvalue is real, then $J_i = \begin{pmatrix} \lambda & 1 & 0 \\ & \lambda & \ddots \\ 0 & & \lambda \end{pmatrix}$

& normal $\longleftarrow = \begin{pmatrix} B_2 I_2 & 0 \\ & \ddots \\ 0 & & B_2 I_2 \end{pmatrix}$

So, let me summarize in detail now, so given a matrix m and r there exists a non-singular C such that C inverse a c , so let me just write $J_1 J_2 J_k$ where each J_1 is a Jordan block corresponding to an Eigen value of a and we have. So, if the Eigen value is real then J_1 would be very simple λ and each J_1 might contain several blocks. So, 1 of the I am just this is not the only possibility there will be several blocks and if the Eigen value is nontrivial then this will be just $B_2 B_2 I_2 I$ that is the only difference ok

(Refer Slide Time: 45:36)

In particular,

$C^{-1}AC = \begin{pmatrix} J_1 & & \\ & \ddots & \\ & & J_k \end{pmatrix}$

Let $\lambda \in \mathbb{R}$ and $J = \begin{pmatrix} \lambda & 1 & 0 \\ & \lambda & \ddots \\ 0 & & \lambda \end{pmatrix}$. What is $e^J = ?$

FACT: If A, B commute, i.e. $AB=BA$, then $e^{A+B} = e^A \cdot e^B = e^B \cdot e^A$

Binomial theorem: If $AB=BA$, then $(A+B)^k = \sum_{j=0}^k \binom{k}{j} A^j B^{k-j}$

So, in particular we have this C inverse a C not C inverse a C exponential E to the J 1 etcetera and in the next ten minutes I will just show you how it easy it is to compute the exponential of each of these blocks. So, let me just again concentrate on that, so let λ real and J is equal to. So, I take one of the blocks.

So, this is a square matrix of some order. So, what is E^J . So, that is the main question. So, again a fact. So, if A and B commute that is AB equal to BA then exponential of $A+B$ is equal to exponential of A exponential of B . So, just like exponential of a real number and in general if you have non commutativity then you may not have equality in this E^{A+B} may be different from $E^A E^B$ and $E^B E^A$, so since addition is commutative we also have this ok and this usually follows from this binomial theorem just like again real numbers. So, if AB equal to BA then $(A+B)^k$ is summation $\binom{k}{j} A^j B^{k-j}$ J a J B k minus J equal to zero. So, this you can easily prove by induction and which in turn give this ok.

(Refer Slide Time: 48:57)

Rewrite $J = \lambda I + B$, $B = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$

$$e^J = e^{\lambda I} \cdot e^B = e^{\lambda} \cdot I \cdot e^B = e^{\lambda} e^B = e^{\lambda} (I + B + \frac{B^2}{2!} + \dots)$$

 B is a nilpotent matrix, i.e. $\exists r \in \mathbb{N}$, s.t. $B^r = 0$
 μ is non-real, $J = \begin{pmatrix} B_2 & I_2 & 0 \\ 0 & \dots & I_2 \\ 0 & \dots & B_2 \end{pmatrix} = \begin{pmatrix} B_2 & 0 \\ 0 & B_2 \end{pmatrix} + \begin{pmatrix} 0 & I_2 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$
 i.e. $e^J = \begin{pmatrix} e^{B_2} & & \\ & \dots & \\ & & e^{B_2} \end{pmatrix} \left[I + B + \frac{B^2}{2!} + \dots \right]$
 Compute $e^{B_2} = e^a \begin{pmatrix} \cos b & \sin b \\ -\sin b & \cos b \end{pmatrix}$
 $B_2 = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$

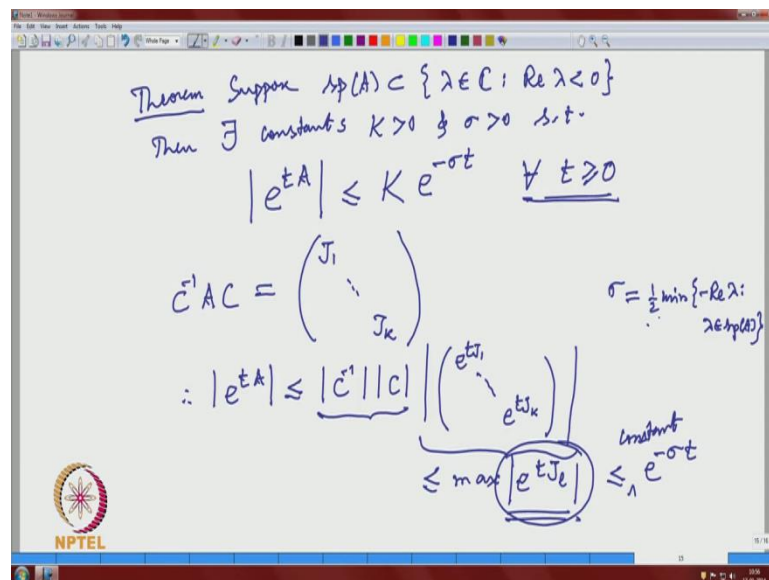

So, that is the only thing involved. So, now we apply this to J . So, rewrite J as $\lambda I + B$, so B is this matrix $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$. So, everywhere 0 except this super diagonal which is just all ones now since this is identity. So, these 2 matrices commute. So, we have this E^{J} is equal to $E^{\lambda I} E^B$ and this you can easily check $E^{\lambda I} E^B$ to the λ is nothing, but $E^{\lambda I}$ into E^B to the b . So, this is identity, so we have just $E^{\lambda I} E^B$ and now let me just expand this, so this is by

definition I plus B plus etcetera the important thing about B is B is a nilpotent matrix that is there is exists some r integer r such that B r is 0, so this is a finite sum.

So, it only goes up to B r minus 1 by r minus 1 factorial and it is very easy to compute even the powers, so this the diagonal containing ones will be just shifted above and above. So, it is very easy to compute. So, and we have this thing and in case lambda is non real. So, mu suppose mu is non real then we have this J as block I 2 I 2 etcetera still we can use, so this we will write it as this B 2 B 2 plus again same thing 0 I 2 0 0 I 0 I 2 etcetera.

So, again this is nilpotent and these two come out, so it is very easy to find therefore, E to the J is again E to the B 2 B 2 into I plus, so let me call this matrix as some d. So, I have d plus d square etcetera. So, this is finite sum, so there is no problem about that finite some and I leave as an exercise. So, remember B 2 is a minus B b a just 2 by 2 matrix, so it is very easy to compute that, so compute E to the B 2 is equal to E to the a minus let me just write that E to the a cos B minus sin B sin B cos this is not difficult to compute that ok.

(Refer Slide Time: 54:05)

So, finally, let me just take this theorem, so you just combine all these things, so suppose spectrum of a is subset of lambda in C such that real lambda is strictly less than 0, so then there exists constants k positive and sigma positive such that the matrix norm of E to the t a is less than or equal to k E to the minus sigma t for all t. So, this is important

this is not valid for all t only for negative and just you have to use is you have this Jordan form $J_1 J_2 \dots J_k$.

So, therefore, you have $\|E^{-t} A\|$ is less than or equal to norm of C inverse norm of C and then you have norm of this matrix $E^{-t} J_1 E^{-t} J_k$ and this is just a confront you leave it and this was already seen that this is less than or equal to maximum of $\|E^{-t} J_l\|$, because these are all block diagonal and now if you use the previous representation you see that σ can be taken as minus half maximum of let me minus real λ in the spectrum of A . So, this is an exercise you can just find that this can be estimated less than or equal to $\|E^{-t} A\| e^{-\sigma t}$ some constant and put another constant here constants will come.

So, there will be some polynomials here polynomials in t coming from this pair and that will be killed by half of this another half. So, that is why you get only half any fraction will do with that we conclude these preliminaries on linear algebra you can work out several things in the some good text on linear algebra and fill the details that are left out in these two hours.

Thank you.
