Lecture 29
Vector Fields 2

Hello and welcome to the 29th lecture in our series. So, last time I just started discussion of vector fields and I wanted to state the smoothness of a vector field in terms of what in terms of coordinate charts.

(Refer Slide Time: 00:48)

$X|_U \mapsto X$

we can write

$$X_v = \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_v$$

where $a_i : U \rightarrow \mathbb{R}$

Proposition: X is smooth if and only if the a_i are smooth.

Proof: Suppose that X is smooth. Let (U, φ) be a chart, and, for $1 \leq i \leq n$, let $\pi_i : \mathbb{R}^n \rightarrow \mathbb{R}$ be the projection onto the i -th coordinate.

if the a_i are smooth.

Suppose that X is smooth. Let (U, φ) be a chart, and, for $1 \leq i \leq n$, let $f = \pi_i \circ \varphi$.

where $\pi_i : \mathbb{R}^n \rightarrow \mathbb{R}$ is $\pi_i(x_1, \dots, x_n) = x_i$.

$$g_f(v) = X_v(f) = \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_v (f)$$

$$= \sum a_i(v) d\varphi^{-1}_{\varphi(v)} \left(\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} \right) (f)$$

$$= \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_{f \circ \varphi^{-1}} (f)$$

$$\begin{aligned}
 \pi_i(x_1, \dots, x_n) &= x_i \\
 g_f(v) = X_v(f) &= \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_v (f) \\
 &= \sum a_i(v) \underbrace{d\varphi_v^{-1} \left(\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} \right)}_{\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} (f \circ \varphi^{-1})} (f) \\
 &= \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_{\varphi(v)} (f \circ \varphi^{-1}) \\
 &= \sum a_i(v) \boxed{\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} (\pi_i)}
 \end{aligned}$$

The following
 If $f \in C^\infty(M)$, then the
 function $g_f: M \rightarrow \mathbb{R}$ defined by
 $g_f(x) = X_x(f)$ is smooth.

Smoothness in a coordinate chart:
 ① Note that if X is a vector field on M ,
 and $f \in C^\infty(M)$, then we get a vector
 field $(fX)_p := f(p)X_p$.
 It is clear that fX is smooth.
 i.e. if $\varphi \in C^\infty(M)$, then
 $x \mapsto (fX)_x(\varphi)$
 $= f(x) X_x(\varphi)$
 $= f(x) \frac{\partial}{\partial x_i} \Big|_x (\varphi)$ is smooth.

So, the proposition was this let us quickly see what we had the proposition what that if I take a local chart then in that local chart I have a natural basis for the tangent space at each point and therefore, the vector field for that matter any individual vector can be expressed as a linear combination of this basis. So in particular express the vector field like this at each q I have this. So, I get a n functions even up to a n on the chart U and the claim is that the smoothness of the vector field is equivalent to smoothness of these functions, that is it.

So, let us see why that is the case. And this is a somewhat this way of thinking about of a vector field less more concrete, because after all what we are saying is just that we are starting with some standard vector fields $\frac{\partial}{\partial x_i}$ and multiplying them by smooth functions and adding them up. So, on the other hand it is always preferable to have a

coordinate free definition of smoothness, so we started with a coordinate free definition then we would like to say that is equivalent to this.

Now, let us see, so I with an if and only if statement suppose let us start with the, suppose that X is smooth in a in the original sense that I define which is a coordinate free sense. So, we know that, now let $U \xrightarrow{f_i}$ be a chart, so I know that I can restrict X to U and get a vector field smooth vector field on U . So, now I want to conclude that these functions are smooth. Well, what I do is it is let this be a chart and I will define some functions let f equals π_i composed with f_i .

So, here as usual U and there is a f_i plus U^1 . Now, this π_i are just the projection maps on \mathbb{R}^n . Let f equal to $f \circ \pi_i$ composed with f_i , so here i is between any number between 1 and n , let f equals this where π_i is the usual projection map on \mathbb{R}^n to the i th coordinate, π_i of $x_1 \times \dots \times x_n$ is just x_i . So, I just look at in effect all I am doing is, so this is to \mathbb{R} this map is I am looking at the i th this f_i has n components $f_{i1}, f_{i2}, \dots, f_{in}$, I am just looking at the i th component of f_i , that is what this composition means.

So, now let us see what let us act X on this function f and see what we get. X composed with rather X at the point q acting on the function f , let us see what this is? This is our what we called df_q earlier when I wanted to talk about smoothness of a vector field, so this by definition in local in this basis that I have, so I will use this $\frac{\partial}{\partial x_i}$ at q acting on f .

Now, this thing here $\frac{\partial}{\partial x_i} f(q)$ remember that $\frac{\partial}{\partial x_i}$ at q was actually given by this expression here, so this is actually df_i^{-1} at $f_i(q)$ and then $\frac{\partial}{\partial x_i}$ the usual $\frac{\partial}{\partial x_i}$ at $f_i(q)$ again acting on f . This looks rather complicated but actually it is just going by definitions it works out to be something simple.

So, well this is a tangent vector and this is a the differential of a smooth map and we know the way we define the differential of a smooth map, this is this expression here is by definition $\frac{\partial}{\partial x_i}$ of f at $f_i(q)$ acting on essentially all I have to do is, I have to compose f composed with f_i^{-1} , that I just by that definition of the differential df_i^{-1} .

Now, I will use the fact that I have taken a specific f , f is equal to $\pi_i \circ f_i$, so this is $\frac{\partial}{\partial x_i}$ of f_i at q , f composed with so the point is that f is this it is π_i composed with f_i , but there is a f_i^{-1} here, so that gives me f_i composed with f_i^{-1} identity, so I am just left with π_i . So, this would be π_i let me write it a bit clear, so this is π_i .

And we know that now this is just the this expression here, we can forget about the manifold actually, we are just in Euclidean space and all we are doing is we are taking the i th partial derivative.

(Refer Slide Time: 10:05)

let (U, φ) be a chart. and, for $1 \leq j \leq n$,
let $f = \pi_j \circ \varphi$
where $\pi_j : \mathbb{R}^n \rightarrow \mathbb{R}$ is
 $\pi_j(x_1, \dots, x_n) = x_j$

$$g_f(v) = X_v(f) = \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_v (f)$$

$$= \sum a_i(v) \underbrace{d\varphi_v^{-1} \left(\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} \right)}_{\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} (f \circ \varphi^{-1})} (f)$$

$$= \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_{\varphi(v)} (f \circ \varphi^{-1})$$

$$= \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_{\varphi(v)} (\pi_j)$$

$$= a_j(v).$$

Since g_f is smooth, so is a_j .
Conversely, if $f \in C^\infty(U)$, then
 $X_v(f) = \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_v (f)$

$$= \sum a_i(v) d$$

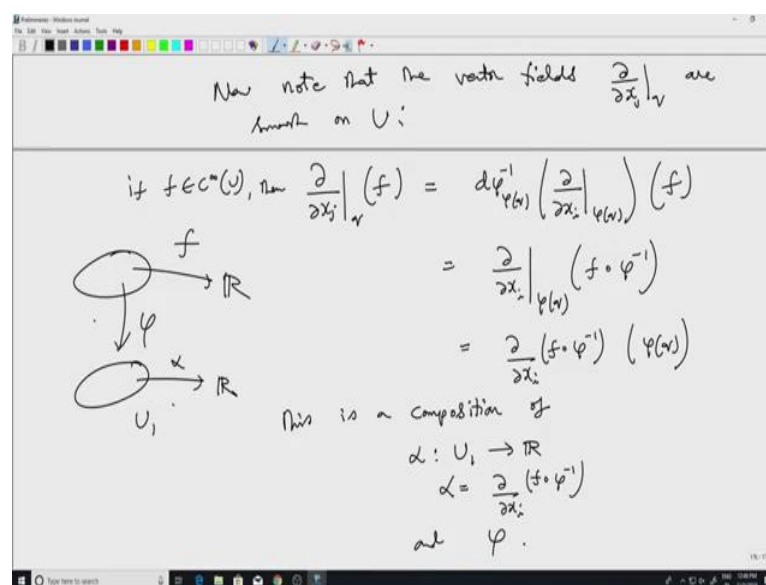

I should be bit careful, let just then index to a bit careful about the index, so let me use the index j here rather than i , so π_j and this is x_j and here as well I would need to be because I am using i for the summation index. So, let us take a j and then here to I would then have π_j . So, what we are doing is we are taking the i th derivative of the j th projection map.

So, and we know that and j th projection map, so here also I should put the j , π_j , so if I take the i th derivative of this map here the only time it will be 0 unless i equals j essentially. So,

that will be, so the only term which will survive those were here the summation is i from 1 to n , only when i equals j , I will get 1 otherwise it is 0. So, I am left with $a_j q$. So, in short what this calculation shows is that the function $a_j q$ is exactly $q \nabla_j f$ where f is if we take f to be of that special thing or special form.

So and we know that $g f q$ is smooth, since $g f$ is smooth, so is a_j for any j between 1 at n . So, that proves that smoothness of the vector field implies smoothness of this functions a_j . And the converse is also quite clear, so conversely, if f is a C^∞ function on U , then $X_q f$ is equal to $a_i q \nabla_i f$ at q of f again this is what this literally means is so $\nabla_j f$ at q it is this thing here, so this expression here that I have here this one and so therefore this is $d f$ inverse, so let me, so in fact rather than stating it this was let us just state it in a cleaner way. So, at least a notational is simpler way a converse then we have this.

(Refer Slide Time: 14:16)

Now note that the vector fields $\frac{\partial}{\partial x_j}|_v$ are smooth on U :

if $f \in C^\infty(U)$, then $\frac{\partial}{\partial x_j}|_v (f) = d\varphi^{-1}_{\varphi(v)} \left(\frac{\partial}{\partial x_i}|_{\varphi(v)} (f) \right)$

$= \frac{\partial}{\partial x_i}|_{\varphi(v)} (f \circ \varphi^{-1})$

$= \frac{\partial}{\partial x_i} (f \circ \varphi^{-1}) (\varphi(v))$

This is a composition of $\alpha: U \rightarrow \mathbb{R}$
 $\alpha = \frac{\partial}{\partial x_i} (f \circ \varphi^{-1})$
 at $\varphi(v)$.

Now, note that the vector fields $\nabla_j f$ at q are smooth on U . Vector fields smooth on U and to see this, this is quite clear but let us see this quickly, so after all what is this $\nabla_j f$ at q , so I have to start with if f is C^∞ function on U , then $\nabla_j f$ at q acting on f is by definition equal to $d f$ inverse at f of q of $\nabla_i f$ at f of q acting on f .

And by the same logic the as before there is a differential of a smooth map acting on a vector acting on a function and that is equal to $\nabla_i f$ at f of q , so you just do f composed with f inverse. And this is nothing but $\nabla_i f$ of f composed with f inverse evaluated at f of q . So, what this short calculation shows is that, if I take a C^∞ function on U and act the coordinate vector field on that I get this expression final expression here.

Now, I want to say that this is a smooth function of q , that is clear because well it is a composition of two smooth functions, this is a composition of after all f_i is the function here to U_1 and on U_1 I have this function the partial derivative function, so let us call it α composition of α from U_1 to \mathbb{R} given by α equals $\frac{\partial}{\partial x_i} \circ f_i^{-1}$ that should come second f composed with f_i^{-1} remember that f was here to \mathbb{R} and this α is also to \mathbb{R} .

This is a smooth function because f is a smooth map and f_i is a diffeomorphism, so f all partial derivatives are smooth, so α is smooth. And then of course the other map is f_i itself and f_i . So, first I come via f_i here and then do α , so composition of this. So, therefore this brief calculation shows that this coordinate vector fields $\frac{\partial}{\partial x_j}$ at q which are actually this are smooth.

(Refer Slide Time: 19:08)

Handwritten mathematical derivation on a digital whiteboard:

$$= \sum_{i=1}^n a_i(v) \left(\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} \right)$$

$$= a_j(v).$$

Since g_f is smooth, so is a_j .

Conversely, if $f \in C^\infty(U)$, then

$$X_q(f) = \sum a_i(v) \frac{\partial}{\partial x_i} \Big|_v (f)$$

Now note that the vector fields $\frac{\partial}{\partial x_i} \Big|_v$ are smooth on U :

if $f \in C^\infty(U)$, then $\frac{\partial}{\partial x_j} \Big|_v (f) = d\varphi_v^{-1} \left(\frac{\partial}{\partial x_i} \Big|_{\varphi(v)} \right) (f)$

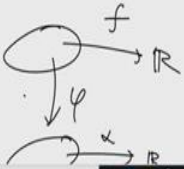

f

Since g_j is smooth, so is a_j .
 Conversely, if $f \in C^\infty(U)$, then

$$X_q(f) = \sum a_i(q) \left. \frac{\partial}{\partial x_i} \right|_q (f)$$

Now note that the vector fields $\left. \frac{\partial}{\partial x_i} \right|_q$ are smooth on U :

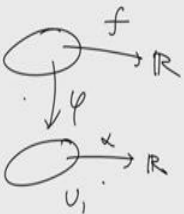

if $f \in C^\infty(U)$, then $\left. \frac{\partial}{\partial x_i} \right|_q (f) = d\varphi_{\varphi(q)}^{-1} \left(\left. \frac{\partial}{\partial x_i} \right|_{\varphi(q)} (f) \right)$

$$= \left. \frac{\partial}{\partial x_i} \right|_{\varphi(q)} (f \circ \varphi^{-1})$$

$$= \frac{\partial}{\partial x_i} (f \circ \varphi^{-1}) (\varphi(q))$$

if $f \in C^\infty(U)$, then $\left. \frac{\partial}{\partial x_i} \right|_q (f) = d\varphi_{\varphi(q)}^{-1} \left(\left. \frac{\partial}{\partial x_i} \right|_{\varphi(q)} (f) \right)$

$$= \left. \frac{\partial}{\partial x_i} \right|_{\varphi(q)} (f \circ \varphi^{-1})$$

$$= \frac{\partial}{\partial x_i} (f \circ \varphi^{-1}) (\varphi(q))$$

This is a composition of

$$\alpha: U_1 \rightarrow \mathbb{R}$$

$$\alpha = \frac{\partial}{\partial x_i} (f \circ \varphi^{-1})$$

and φ .

$\therefore X|_U$ is smooth for every coordinate chart (U, φ) . $\therefore X$ on M is smooth.

And now going back to the original vector field X , we have seen that this coordinate vector fields are smooth and I am multiplying by smooth function a_i , that is not j there it should be i and likewise here not that the vector fields $\frac{\partial}{\partial x_j}$ as for some reason the i 's and j 's got mixed up here, so let us just stick to i so this is an i here, this is an i .

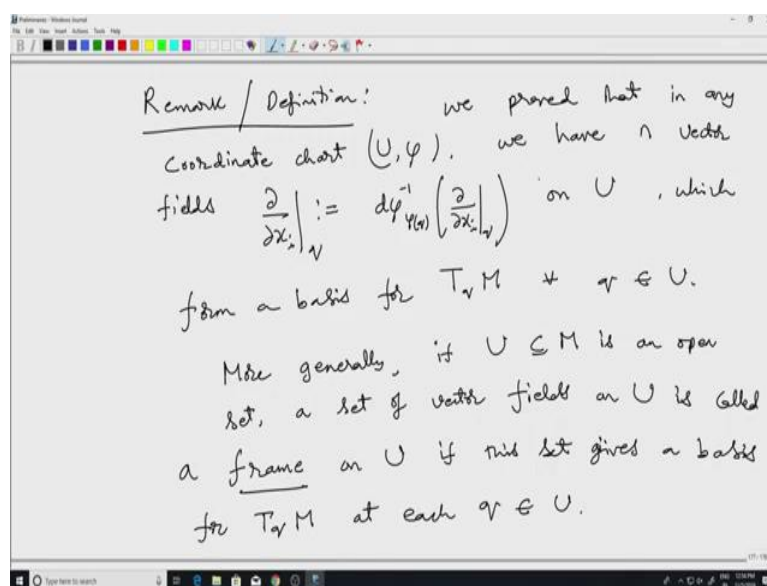

So, the coordinate vector fields are smooth and I am multiplying each coordinate vector field by a smooth function and therefore, the product is smooth and therefore the sum will be smooth as well. So, this what this we can conclude is that $X|_U$, so this where restriction of the vector field X , therefore X restricted to U is smooth.

For every coordinate chart we are assured that this functions a_i that we get are smooth therefore, X restricted to every coordinate chart is smooth for every coordinate chart U_i well

we have already seen that the smoothness of f smoothness of the vector field X on the whole manifold is equivalent to smoothness of X on any open set, here of course we are not I mean it is not necessary that we use every open set any covering by open sets is good enough and we have used coordinate charts.

So therefore, X on M is smooth. The point is smoothness is always whether it is a local issue whether we are talking about smoothness of maps or smoothness of vector fields and so on. So, that is more some technical discussion about smoothness.

(Refer Slide Time: 21:48)

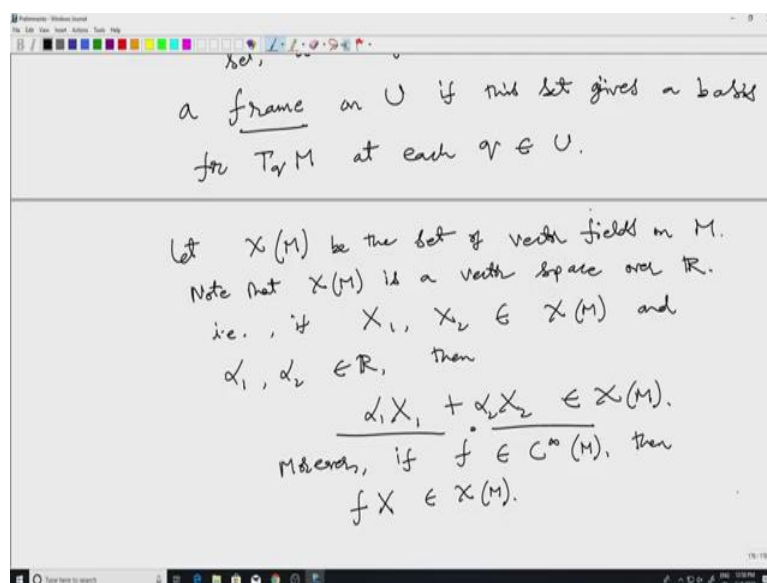

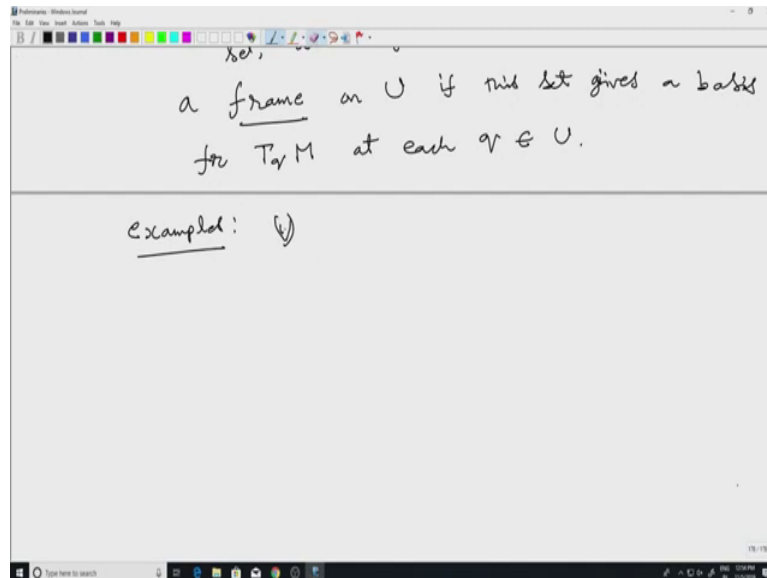

Now, let us I will make a remark slash definition in the course of the proof we saw that, we have proved that in any coordinate chart, U fi, we have n vector fields $\frac{\partial}{\partial x_i}$ at q which of course what it means I will put with in brackets, no may be not the bracket will make it to look a bit odd. So, let us just say as $d\varphi^{-1}_{\varphi(q)} \left(\left. \frac{\partial}{\partial x_i} \right|_q \right)$, so this is defined to be this.

We have n vector fields on U which form a basis for $T_q M$ for all q in U , such a set of vector fields as a name it is called a frame more generally frame, if U contained in M is an open set, a set of vector fields on U is called a frame on U if this set gives a basis for $T_q M$ at each q in U .

So, in general one cannot guaranty the existence of a frame if once start with an arbitrary open set for example if U equals M all of M we cannot say that there is set of vector fields on M which forms a basis for the tangent space at each point, what we can say and we have seen

is that if you take U to be a coordinate chart, then there is frame on U . So, now let us move on to some examples for vector fields.

(Refer Slide Time: 26:15)

Well, we have already seen that, now it will be convenient to introduce a notation, so before I start writing down the examples let us, so let χ of M be the set of vector fields on M . Note that this is actually a vector space note that χ of M is a vector space over \mathbb{R} . i.e, if X_1 and X_2 are two vector fields and $\alpha_1 \alpha_2$ are two real numbers, then $\alpha_1 X_1$ plus $\alpha_2 X_2$ is again vector field of in our definition the way we are defined a vector field is automatically smooth, smoothness is part of the definition, so now this statement here it is not saying much all it saying is that if I start with a vector field I can multiplied it by a real number and get another smooth vector field.

So, that is here $\alpha_1 X_1$ and $\alpha_2 X_2$ are smooth vector fields and if I have two smooth vector fields I can add them up and get another smooth vector field. So, it is an easy trivial exercise to check that some of two smooth vector fields is again smooth in constant times a smooth vector field is smooth in fact we have shown something stronger we have seen that if we have a not just a constant if we have a smooth function on M f times X is again a smooth vector field.

So, let us observe that in moreover if f is in $C^\infty(M)$ then f times X , which we define as which we define earlier is again a smooth vector field. Now, actually this, so the vector space part was already done before introducing this smooth this $\alpha_1 X_1$ plus $\alpha_2 X_2$ part, $\alpha_2 X_2$ being in χ of M ensures that χ of M is a vector space an additional comment is that if we have a C^∞ function then f times X is also a vector field.

Well algebraically what this amounts to saying is that, the set of vector fields is not a just a vector space over \mathbb{R} it is a module over the ring of C^∞ functions, C^∞ functions on M forms a it is a ring with usual addition and multiplication of functions and the fact that we can multiply a vector field by a function to get another vector fields is that a set of vector fields is a module over this ring.

But for us what is relevant is that first let us start by observing that this there always a trivial vector field and namely the 0 vector field, so at every point you just take the 0 vector, but in fact there is something much stronger what will I will briefly outline next time is the simple fact that if you have any tangent vector on a manifold there is a vector field on the manifold which gives the tangent vector at that point. So, let us stop here and we will resume next time. Thank you.
