

An Introduction to Smooth Manifolds
Professor Harish Seshadri
Department of Mathematics
Indian Institute of Science, Bengaluru
Lie Brackets (Part 2 of 2)

Hello and welcome to this discussion on vector fields and in particular, Lie brackets.

(Refer Slide Time: 0:40)

$[,] : \mathcal{X}(M) \times \mathcal{X}(M) \rightarrow \mathcal{X}(M).$
 Let $p \in M$,
 $f \in C^\infty(M)$
 $[X, Y]_p(f) := X_p(Y(f)) - Y_p(X(f))$
 Note not $Y(f) : M \rightarrow \mathbb{R}$
 with $Y(f)(x) = Y_x(f).$

prop: 1) $[X, Y]_p$ is a derivation at p .
 2) $[X, Y]$ is smooth.

prop: 1) $[X, Y]_p$ is a derivation at p .
 2) $[X, Y]$ is smooth.

pf: Let $f, g \in C^\infty(M)$
 $Y(fg)(x)$
 $= Y_x(fg)$
 $= f(x)Y_x(g) + g(x)Y_x(f)$
 $= f Y(g) + g Y(f)$

$[X, Y]_p(fg)$
 $\stackrel{?}{=} f(p)[X, Y]_p(g) + g(p)[X, Y]_p(f)$
 L.H.S. $= X_p(Y(fg)) - Y_p(X(fg))$
 $= X_p(f Y(g) + g Y(f)) - Y_p(f X(g) + g X(f))$
 $= X_p(f Y(g)) + X_p(g Y(f)) - Y_p(f X(g)) - Y_p(g X(f))$

So, last time I defined this operation starting with two vector fields. So, the main definition is here. Notice that one actually needs vector fields, tangent vectors will not do because I need to

get a function here on the manifold in order to act Xp on that and in order to get a function, well, I have to have Y defined at all points on the manifold. So, now let us check, let me quickly start the checking the derivation property of this. I will not complete this, it is fairly straightforward.

So what does it, yeah, so what do we have to check? Now before I start checking I, I should write the second part. Second thing is that $X Y$ is smooth, in other words it is indeed a (vec) what we called a vector field, as p changes smoothly, this $X Y$ changes. So, to check let f, g belong to $C^\infty(M)$. So, what I want to do is, I want the Leibniz's rule to hold. So, I want $X Y p$ acting on fg , we want to verify whether this is f of $p X Y p$ acting on g plus g of $p X Y p$ acting on f .

So, this is, so let us say that, I will put a question mark here is this equal to the right-hand side. So it is just a matter of going through the definition, so for instance, the left-hand side, the L.H.S., L.H.S. equal to $Xp Y$ now the function here is fg minus $Yp X fg$. Now here, when Y acting on fg , so let us look at this Y acting on fg , now the point is this is a function on the manifold. So, let us see its value at any point X is Yx acting on fg , by definition.

And now this is a, once I take an X , this is a tangent vector and then I use the derivation property for this, so this would be f of $x Yx g$ plus g of $x Yx f$ which I can write as, now, if I do not want to mention X at all, this (eq), the above equation amounts to same that Y of fg equal to f , this function f multiplied by Y of g plus g multiplied by the the function Y of f . So when, we can use this without mentioning X , so instead of $Y f g$ I put f times $Y g$ plus g times $Y f$, f times $Y g$ plus g times $Y f$.

And similar thing here, so I will, I will not complete the calculations, it is fairly straightforward, so you do a similar thing here then, you again use the derivation property of Xp , so here that will give me, two terms here two, so altogether there will be four terms coming from this one, this, and another four from this. One combines the appropriate terms and writes it in this form that is it. Notice that some cancellations will also take place and then one gets what one wants.

(Refer Slide Time: 6:06)

Smoothness: $g(x) = [X, Y]_x(f) = X_x(Yf) - Y_x(Xf)$
ex: on \mathbb{R}^n , if $X = \frac{\partial}{\partial x_i}$ $Y = \frac{\partial}{\partial x_j}$
 Then $[X, Y]_p(f)$

$$= \frac{\partial}{\partial x_i} \bigg|_p \left(\frac{\partial f}{\partial x_j} \right) - \frac{\partial}{\partial x_j} \bigg|_p \left(\frac{\partial f}{\partial x_i} \right)$$

$$= \frac{\partial^2 f}{\partial x_i \partial x_j} (p) - \frac{\partial^2 f}{\partial x_j \partial x_i} (p)$$

$$= 0$$

So now, as for smoothness, if one uses the the definition of (smoo) instead of using local coordinates, one just goes by definition of smoothness, one has to look at this, $X Y$ so the function, this function for any f in $C^\infty(M)$. So this is what I have, sometimes called $g(X, Y)$ equal to this. Smoothness, one just looks at this and this by definition is X at x Y of f minus Y at x X of f .

Now, since individually X and Y are smooth vector fields, this thing here is a smooth function and so is this thing, $Y f$ and $X f$ are smooth functions again the fact that X is smooth will say that this is also a smooth function where the variable is X , likewise this, so, overall you will get a smooth function. So, it is quite straight forward. So let us look at some examples of lie bracket. Oh, when I was, one brief remark, when I I just checked the Leibniz's rule property but linearity is even more clear.

So here linearity with respect to the function f , if I take two functions, add them up f and g then it is clear that the right-hand side is linear as well. So the Leibniz's rule is the only thing to check there. Now, as an example let us just take a trivial thing but very important example. So, let U contained an \mathbb{R}^n , actually you do not even need the open set let me take the whole manifold on \mathbb{R}^n if X equal to $\frac{\partial}{\partial x_i}$, Y equal to $\frac{\partial}{\partial x_j}$ are the two basis vector fields, then, let us see what $X Y$ is. $X Y$ acting on f would be, X is $\frac{\partial}{\partial x_i}$ at a point p .

So, let us say $\text{del by del } x_i \text{ at } p$ acting on Y of f , now Y of f is just $\text{del } f \text{ by del } x_j$ minus $\text{del by del } x_i \text{ del by del } x_j \text{ at } p$ acting on $\text{del } f \text{ by del } x_i$. But this thing, both these are what one usually denotes by mixed, what one usually means by mixed partial derivatives, and they are denoted like this $\text{del squared } f \text{ by del } x_i \text{ del } x_j \text{ at } p$ minus $\text{del squared } f \text{ by del } x_j \text{ del } x_i \text{ at } p$.

And we know from multi variable calculus that mixed partial derivative for a smooth function, mixed partial derivatives are equal, so therefore this is 0. So, if we start with any two elements any two vector fields, the standard vector fields namely partial derivative vector fields the lie bracket is 0.

(Refer Slide Time: 10:37)

prop: let $f: M \rightarrow N$ be a smooth map.
 Suppose $X_1, X_2 \in \mathcal{X}(M)$ are f -related to
 $Y_1, Y_2 \in \mathcal{X}(N)$. Then
 $[X_1, X_2]$ is f -related to $[Y_1, Y_2]$.
proof: let $\varphi \in C^\infty(N)$.

$$df_p([X_1, X_2]_p)(\varphi)$$

$$= [Y_1, Y_2]_{f(p)}(\varphi)$$

$$= [Y_1, Y_2]_{f(p)}(\varphi)$$

$$\begin{array}{l|l} X_2 \text{ related to } Y_2 & \text{L.H.S.} \\ \hline d\varphi(X_1) = Y_2 & = [X_1, X_2]_p(\varphi \circ f) \\ d\varphi(X_1)(\varphi) = Y_2(\varphi) & = (X_1)_p(X_2(\varphi \circ f)) - (X_2)_p(X_1(\varphi \circ f)) \\ X_2(\varphi \circ f) = Y_2(\varphi) & = (X_1)_p(Y_2(\varphi \circ f)) - (X_2)_p(Y_1(\varphi \circ f)) \\ & = df_p((X_1)_p)(Y_2(\varphi)) - \dots \\ & = (Y_1)_{f(p)}(Y_2(\varphi)) - (Y_2)_{f(p)}(Y_1(\varphi)) \\ & = Y \end{array}$$

$$\begin{array}{l} X_2(\varphi \circ f) = Y_2(\varphi) \\ \hline = df_p((X_1)_p)(Y_2(\varphi)) - \dots \\ = (Y_1)_{f(p)}(Y_2(\varphi)) - (Y_2)_{f(p)}(Y_1(\varphi)) \\ = [Y_1, Y_2]_{f(p)} \end{array}$$

Well, the significance of this I will come back to later but for now I need one proposition relating so, let f from M to N be a smooth map. Suppose, X_1, X_2 are two vector fields f related to Y_1, Y_2 on N then, the lie bracket of X_1, X_2 is f related to Y_1, Y_2 . So this, the notion of f related ties in nicely with the this lie bracket property and proof is again a straight forward computation, so here so what, it just a matter of knowing what one has to check to say that this is f related to Y_1, Y_2 amounts to saying checking the following.

Let φ be a C^∞ function on N . Then we are asking the question if df, df_p of X_1, X_2 at the point p act. So this acting on φ is the same as Y_1, Y_2 at the point. Now df_p of this f related amounts to same that this is the same as f of p acting on φ . So again a question mark here, so

this is what we are trying to verify, so let us see how it goes. Now this, the left-hand side, the left-hand side is equal to, by definition of the differential of a smooth map this is the same as $X_1 X_2$ at p acting on ϕ , it is ϕ composed with f .

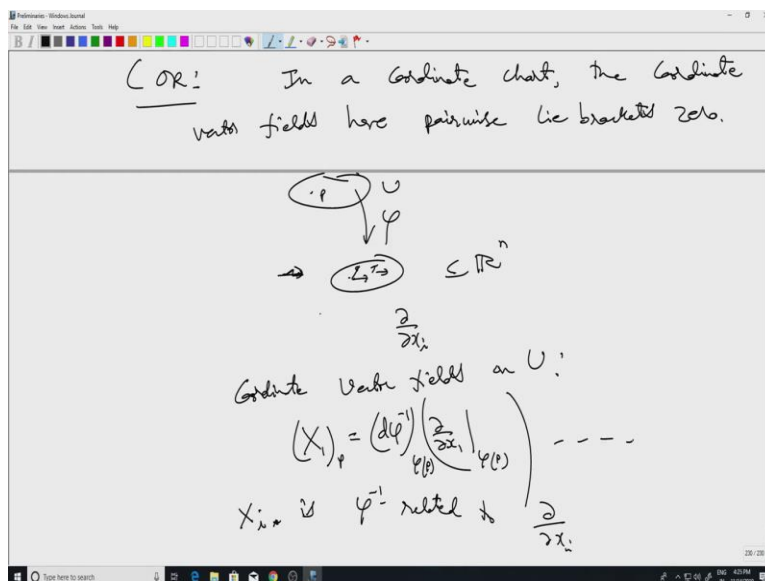

Now I use the definition of the Lie bracket, so this is X_1 at p . Actually, yeah, somewhat inconvenient to retain this p . X_1 at p X_2 of ϕ composed with f minus X_2 at p X_1 of ϕ composed with f and then this brackets. So, now I know that it is just a matter of now unravelling the various hypothesis so for instance, X_2 is f related to, $X_2 f$ related to Y_2 , this just means that df of X_2 at the appropriate point is equal to Y_2 at the appropriate point.

So, if I actually act it on some function, so in particular, so $X_2 df$ of X_2 so right, if I act it on a function which I call the function ϕ , $df X_2$ acting on ϕ equal to Y_2 acting on ϕ and this would be the same as, well it is X_2 acting on actually f composed with, rather ϕ composed with f . So in short X_2 of ϕ composed with f is just Y_2 of ϕ , everything has to be considered at the appropriate points so, for instance, right, so if X_2 is at p then Y_2 would be at f of p .

So, here this would be $Y_2 \phi$ at f composed with f . $Y_2 \phi$ is a function, and I am evaluating it at f of something, so this is like this – X_2 of p it is the same thing with X_1 and Y_1 will give me this. Again, go back to the definition of differential of a smooth map this would be, df , df of, well, $X_1 p$ acting on the function $Y_2 \phi$, similar term here, so let us write, actually here just to be clear I will just put dot, dot, dot. So you will get a corresponding term on the other thing.

So let me just focus on one term, simplifying one term so that will be, and finally, well what is, yeah, again I use the fact that, right, so this is actually at p . So this would be Y_1 , the fact Y_1 at f of p $Y_2 \phi$ and the second term will turn out to be Y_2 at f of p Y_1 at ϕ . Just by definition, the Lie bracket of $Y_1 Y_2$ at the point f of p which is what I wanted. So this is what I wanted and I get that. So, one has this very important and useful fact that f related vector fields go to f related vector fields under the operation of Lie bracket.

(Refer Slide Time: 18:58)

So in particular, one corollary of this is that in a coordinate chart, the coordinate vector fields have pair wise lie brackets zero. So remember that for us, coordinate vector fields so, this is a coordinate chart to something in \mathbb{R}^n . On \mathbb{R}^n , at each point we have this $\frac{\partial}{\partial x_i}$. We have a local, we have a frame on \mathbb{R}^n so, we have $\frac{\partial}{\partial x_i}$ here at each point and when we pull this back to the manifold why had this using the diffeomorphism φ , we get vector fields on this open set U which we called coordinate vector fields.

So the coordinate vector fields are by definition, coordinate vector fields on U are basically at the point p if I start with a point p , I just look at, so let us see if I, X_1 equal to, so I look at the corresponding point, $\frac{\partial}{\partial x_i}$ at the point $\varphi(p)$. This is the here, and then use the φ^{-1} , derivative of φ^{-1} , $d\varphi^{-1}$ at the point $\varphi(p)$. So this is X_1 at p , what I have written here, so we have seen this many times before, usual.

So, here the thing is that this X_1, X_2 et cetera are φ^{-1} related to $\frac{\partial}{\partial x_i}$. X_i is φ^{-1} related to $\frac{\partial}{\partial x_i}$. I just wrote the X_1 equation here but, so this is this is just, the very definition of this coordinate vector fields shows that they are related like this. Since we have already seen that the coordinate vector (fields) the standard partial derivative vector fields have lie bracket 0, the same result holds for this X_i as well.

(Refer Slide Time: 22:35)

The lie bracket in a coordinate chart:

$$\{ (U, \varphi)$$

$$X, Y \in \mathcal{X}(M),$$

$$X = \sum_{i=1}^n a_i \frac{\partial}{\partial x_i} \quad Y = \sum_{j=1}^n b_j \frac{\partial}{\partial x_j}$$

$$a_i, b_j : U \rightarrow \mathbb{R}.$$

Algebraic properties of $[\cdot, \cdot]$:

- 1) If $X_1, X_2, Y \in \mathcal{X}(M)$, $a, b \in \mathbb{R}$, then

$$[aX_1 + bX_2, Y] = a[X_1, Y] + b[X_2, Y]$$
- 2) If $X, Y \in \mathcal{X}(M)$

$$[X, Y] = -[Y, X]$$
- 3) 1) + 2) \Rightarrow If $X, Y_1, Y_2 \in \mathcal{X}(M)$, $a, b \in \mathbb{R}$, then

$$[X, aY_1 + bY_2] = a[X, Y_1] + b[X, Y_2]$$

Now let us see what the lie bracket looks like in a, the lie bracket in a coordinate chart. I will fix a chart U, φ and then let, so I will just take two vector fields X and Y on M . We know that, as just talked about in the last page that, on U we have this frame, in other words n vector fields X_1, X_2, \dots, X_n which form a basis for the tangent space at each point of U . Therefore, I can write, as we have done earlier X equal to a_i . Ah, I should mention one thing, so, the U , I will follow the usual convention. So, instead of writing this X_1 et cetera. I will just use $\frac{\partial}{\partial x_i}$, here as well.

So, $\text{d}\phi$ by $\text{d}\phi$ is used for on \mathbb{R}^n as well as on the manifold. On the manifold what we actually mean is $\text{d}\phi$ inverse of $\text{d}\phi$ by $\text{d}\phi$ is. So I will write it as $\text{d}\phi$ by $\text{d}\phi$ and then Y equal to some other function, like this, so here i equal to 1 to n , j equal to 1 to n again and this a_i and b_j are both functions from, C^∞ functions from U to \mathbb{R} .

So let us see what this is, so X Y , so before I proceed, let us make a few general comments about the Lie (bracket) algebraic properties of Lie brackets. So, let algebraic properties of the Lie bracket, the (first) what I need here is that, it is what is called bilinear in both input variable. So in other words, if X Y are two vector fields on M and if you have two real numbers a b . Actually I need, right, let me take three vector fields.

If X_1 X_2 Y and then a b are two real numbers, Lie bracket of $a X_1$ plus $b X_2$ with Y , this is same as $a X_1$ Y plus $b X_2$ Y . Similarly, X Y are two vector fields then the Lie bracket of X Y is the negative of the Lie bracket of Y X , so this will automatically, if I combine this and this one and two, I see that the third property even in the last second slot as well one has linearity like this.

So 1 plus 2 implies if X Y_1 Y_2 are two three vector fields and you have two real numbers then X $a Y_1$ plus $b Y_2$ is equal to $a X$ Y_1 plus $b X$ Y_2 . Now there is a, actually these are the trivial properties there is something more unexpected which happens here which has to do with three vector fields which I will, I will not mention it now, for now let us just use these and simplify our calculation, go back to this coordinate chart.

(Refer Slide Time: 28:01)

$$\begin{aligned}
 & \text{3.4) } 1) + 2) \Rightarrow \text{ If } X, Y_1, Y_2 \in \mathcal{X}(M) \\
 & \quad \quad \quad a, b \in \mathbb{R}, \text{ Then} \\
 & \quad [X, aY_1 + bY_2] = a[X, Y_1] + b[X, Y_2] \\
 & \quad \quad \quad \underline{\hspace{10em}} \\
 & [X, Y] = \left[\sum_i a_i \frac{\partial}{\partial x_i}, \sum_j b_j \frac{\partial}{\partial x_j} \right] \\
 & \quad = \sum_i \left[a_i \frac{\partial}{\partial x_i}, \sum_j b_j \frac{\partial}{\partial x_j} \right] \\
 & \quad = \sum_{i,j} \left[a_i \frac{\partial}{\partial x_i}, b_j \frac{\partial}{\partial x_j} \right]
 \end{aligned}$$

So, in the coordinate chart I had this, so this I can write as lie bracket of summation of a_i del by del x_i summation b_j del by del x_j . I, now I can use the linearity in the. So, if I keep, if I have two sum of two vector fields and I keep the second, the I think fixed have a splitting like this so that is what I will do here. First I will write it as summation over i lie bracket of a_i del by del x_i , then this is kept fixed, b_j del by del x_j .

Then I will keep this del by del x_i fixed and then expand this over that. So summation over i, j $a_i b_j$ and then, oh sorry, yeah well. These are not for constants, this this holds only for constants so here I cannot take out this a_i , so I have to keep it inside the, it is in. So here, what one gets is, right. So summation and then the a_i will stick with this and similarly here, this, one cannot take it out so, here what one gets is a_i del by del x_i , b_j del by del x_j .

Both within brackets. And, in my next lecture I will simplify this, and we will see it is yeah, it is (jus) mainly for computational purposes it has no special significance, the expression that we are going to get. And, then I will talk a bit about lie bracket of, lie brackets of left invariant vector fields. Okay, thank you.
