Orientation on Manifolds 3
Lecture 68

Hello, and welcome to the last lecture in this series. So, let us, this will be all about orientation. So last time I sketched an argument that having a non vanishing, nowhere vanishing n form on a smooth manifold gives rise to a system, a collection of charts an atlas in fact, such that with the property that the transition functions have positive determinants of their derivatives. And such an atlas is called an oriented atlas.

(Refer Slide Time: 1:15)

And the way we picked out this atlas is quite simple, we just pull back the form to an open set in \mathbb{R}^n . And once we pull it back, it will be some function times the standard n form and we just demand that the function be positive. Well, the moment you pick out those charts which have this property, then we showed that the transition functions have the required property, namely this thing here. This is the object we are concerned with, so, and this turned out to be positive because this is positive as well as well, the right side this is positive. Now, two things. Yeah, so what we have to check is that, so what we have shown is that we can get, we can define a system of charts this way. But it is not clear that, well to begin with, are there any charts of this form and are there enough of them to cover M ? Well, both questions are easily answered by noting that we can always get such charts.

(Refer Slide Time: 2:54)

$$\omega = f dx_1 \wedge \dots \wedge dx_n \quad \text{with } f > 0$$

$$\frac{(g \circ \varphi_p \circ \varphi_q^{-1})^* \omega}{(\varphi_p \circ \varphi_q^{-1})^* \omega} = \frac{(\varphi_p \circ \varphi_q^{-1})^* ((\varphi_q^{-1})^* \omega)}{(\varphi_p \circ \varphi_q^{-1})^* \omega} = (\varphi_q^{-1})^* \omega = \frac{1}{\det(d(\varphi_p \circ \varphi_q^{-1}))} \omega$$

$$U \xrightarrow{\varphi_q^{-1}} V \xrightarrow{\varphi_p} W \quad U \xrightarrow{f} V \xrightarrow{\omega}$$

$$T^* \omega = (\det T) \omega \quad \boxed{f^* \omega = \det(df) \omega}$$

Note that if $\{(U_i, \varphi_i)\}$ is any atlas for M , we can modify φ_i to $\tilde{\varphi}_i$ so that $\{(U_i, \tilde{\varphi}_i)\}$ is an oriented atlas.

So note that if U_α, ϕ_α is any atlas for M not necessarily oriented, we can modify it, modify the chart diffeomorphisms, let us call it $\tilde{\phi}_\alpha$, so that $U_\alpha, \tilde{\phi}_\alpha$ is, this is an oriented atlas. And since the original collection of open sets U_α covered M , and this will, well we are not really changing the U_α at all. So this fact that this cover M is as follows from the original property. Then the only thing we are changing are these maps ϕ_α and the way we modify them is, so recall that what we need actually to conclude to get an oriented atlas is that this, when I pull back the form to \mathbb{R}^n , I should get a positive function here, this f should be positive.

(Refer Slide Time: 4:40)

Let's assume U_α is connected, ϕ_α is a diffeomorphism, so $\phi_\alpha(U_\alpha) \subset \mathbb{R}^n$.

If (U_α, ϕ_α) is a chart and $(\phi_\alpha^{-1})^* \omega = f dx_1 \wedge \dots \wedge dx_n$ with $f < 0$, then define $T: \mathbb{R}^n \rightarrow \mathbb{R}^n$ by $T(x_1, x_2, \dots, x_n) = (x_2, x_1, \dots, x_n)$.

$T^{-1} = T$

$dT(c_1, \dots, c_n) = (c_2, c_1, \dots, c_n)$

$\det(dT) = -1 < 0$

Let $\tilde{\phi}_\alpha = T \circ \phi_\alpha$

$(\tilde{\phi}_\alpha^{-1})^* \omega = (\phi_\alpha^{-1} \circ T^{-1})^* \omega = T^*(\phi_\alpha^{-1})^* \omega$

So let us start with the chart and pull back U_α, ϕ_α is a chart and $\phi_\alpha^{-1} \star \omega$ equal to $f dx_1, dx_n$ with. Here I make the observation that by always taking slightly smaller charts if necessary smaller open sets U_α , we can assume U_α is connected for all α and hence, so is $\phi_\alpha(U_\alpha)$, these open sets in \mathbb{R}^n that we get we can assume are connected. Well once it is connected and I write it like this, then I know that this is a nowhere-zero form this side, the left hand side is nowhere-zero. Therefore, this function is nowhere-zero. Hence it is either strictly positive or strictly negative.

So let us, if it is strictly positive, we are in good shape. So if it is strictly negative, then define, I will just, what I will do is just interchange, use a reflection in the first two coordinates in \mathbb{R}^n , then define T from \mathbb{R}^n to \mathbb{R}^n by T of x_1, x_2 , etcetera, x_n to be just x_2, x_1, x_3 , the other stuff, other coordinates will be kept as they are. So I just interchange, this is a linear map and therefore its derivative dT is just itself, dT of c_1, c_2, c_n is c_2, c_1, c_n . And the main property of this that we need is the, if you write down the matrix, it is just similar to

what we had done earlier. The determinant of the derivative of this will be is actually equal to minus 1, but what we need that it is negative.

So, then let $\tilde{\phi}$, the new chart map be $\tilde{\phi}$ of $\tilde{\phi}$ alpha be, first let us do ϕ alpha and then compose with this T . Well, so now let us see what the pullback form looks like. When I pull back this, I will get this, actually when I do inverse already the order gets switched, ϕ alpha inverse would be, first I will have to do T inverse then ϕ alpha inverse and then I have to do a star, in which case order again gets flipped, T inverse. Also, yeah, let us, the way T has been defined actually T inverse is equal to T . If I apply it in T twice, I will just get back to the original one. So, I need not actually continue to write T inverse, but let us just, T composed with, T upper star composed with ϕ alpha inverse upper star ω .

(Refer Slide Time: 9:46)

$$d\tau(x_1, \dots, x_n) = (x_1, x_1, \dots, x_n)$$

$$\det(d\tau) = -1 < 0$$

$$\omega = dx_1 \wedge \dots \wedge dx_n \quad \text{Let } \tilde{\phi} = T \circ \phi_\alpha$$

$$(\tilde{\phi}^{-1})^* \omega = (\phi_\alpha^{-1} \circ T^{-1})^* \omega$$

$$= T^* (\phi_\alpha^{-1})^* \omega$$

$$= T^* (f \omega_\alpha)$$

$$= (f+T) \cdot T^* (\omega_\alpha)$$

$$= (f+T) \cdot \det(d\tau) \omega_\alpha$$

$$= -(f+T) \omega_\alpha$$

$$> 0$$

$\{(U_\alpha, \phi_\alpha)\}$ is called an oriented atlas.

Suppose we have a nonempty n -form $\omega \in \wedge^n(T^*U)$.

$(\phi_\alpha^{-1})^* \omega = f dx_1 \wedge \dots \wedge dx_n$
 $f \in C^\infty(\text{open set})$

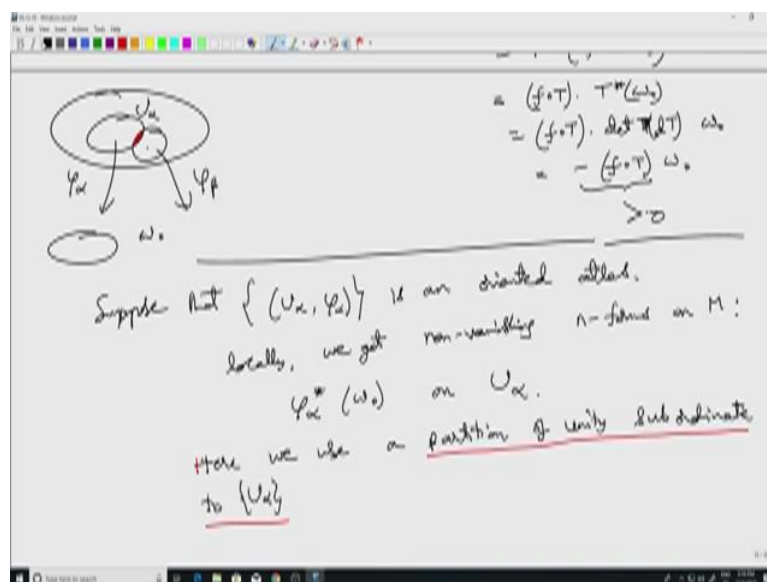

$(\phi_\beta^{-1})^* \omega = g dx_1 \wedge \dots \wedge dx_n$
 $g \in C^\infty(\text{open set})$

we define an oriented atlas as follows: $\{(U_\alpha, \phi_\alpha) : (\phi_\alpha^{-1})^* \omega > 0\}$

Equal to, this was what we are called f , T star of f of well dx^1 , so which is ω naught, using the notation ω naught for the standard n form. So this is equal to this and this we know is the same thing as f composed with T and here is the, actually at this point is the, we know that for a linear transformation, this will be determinant of T and then, here I did determinant of derivative of T but in this case, I really do not, yeah, okay, maybe I can use that, it will be the same in this case.

Determinant of dT times ω naught, which is minus f composed with T of ω naught. So in short for this new chart map, I have got a function here, which is strictly positive, because f itself was negative. So just by modifying this, by entertaining the first 2 coordinates, I can rectify so that I have this required property that all of these functions here are positive. And the moment I do that, we have seen that we will get an oriented atlas.

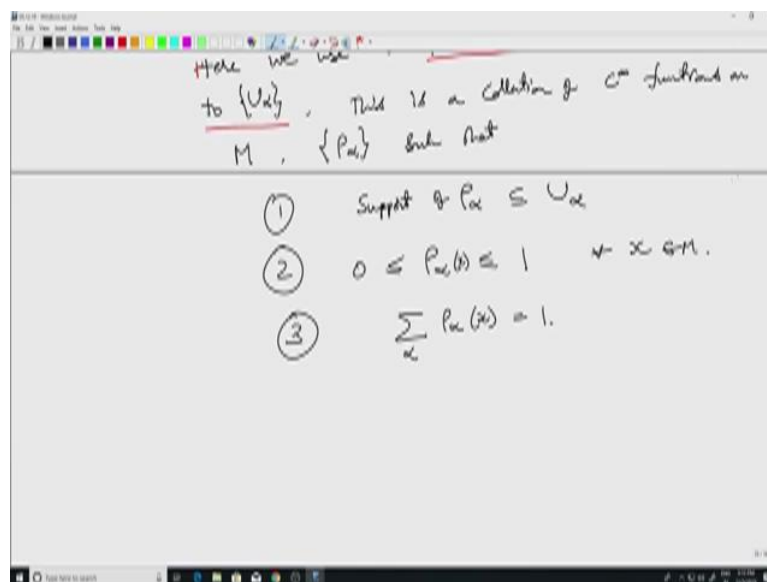

(Refer Slide Time: 12:06)

And conversely, if this is an oriented atlas φ_α, U_α , φ_α is an oriented atlas. Suppose that U_α, φ_α is an oriented atlas, we would like to construct, come up with nowhere-zero n form on the manifold. Well we can certainly do that, so on locally, in fact, we do not even need oriented atlas. Let, like in the previous construction we had an n form on the manifold and we use charts to get n forms on open subsets of \mathbb{R}^n , here we go the other way. So, take a chart, here you have a standard n form ω naught and this is the chart map φ_α, U_α . So, I just pull it back to U_α , $\varphi_\alpha^* \omega$ naught and this will be defined on U_α .

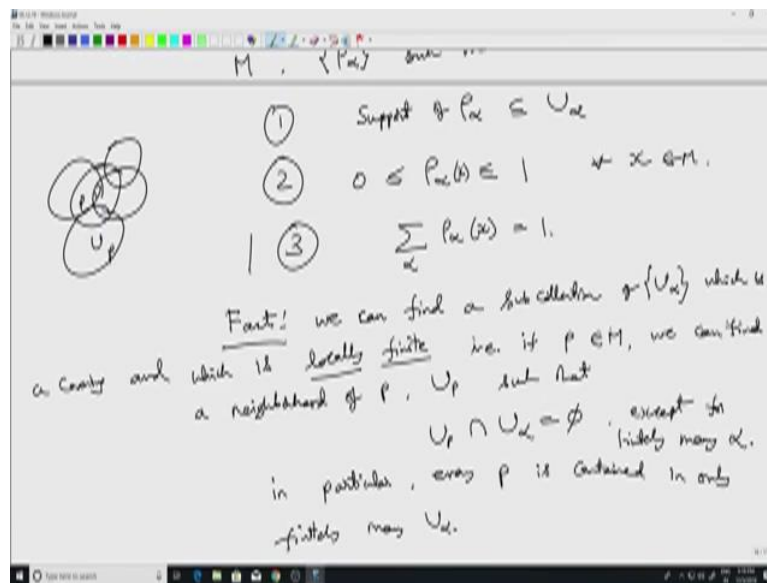

Well there, now the question arises as to how these, how to patch these up. So, these are on every open set, there will be about an n form and we cannot ensure that for instance that suppose I have a ϕ_β and on this intersection the form $\phi_\alpha \star \omega_\alpha$ and $\phi_\beta \star \omega_\beta$ that they actually agree on the intersection is something that we cannot insure. So, what here we have to use a device which I did not actually have occasion to use throughout the course, but which is actually one of the most useful things in the context of starting with locally defined objects and getting a global object on a manifold, namely this thing called, here we use a partition, what is called a partition of unity subordinate to \mathcal{U}_α , the open cover \mathcal{U}_α .

(Refer Slide Time: 15:57)

So now let me briefly say what this is, I will not go into the construction of this, so this is a collection of C^∞ functions on M which we denote by ρ_α , the same index set as the this thing, as a cover, such that the support of ρ_α is contained in U_α . Each ρ_α , values of ρ_α lie between 0 and 1 for all x in M and here is the last one is the reason why this named partition of unity, is the reason why these phrase is used, partition of unity. So, the summation of $\rho_\alpha(x)$, for all α is 1. Now, for this to even, the last condition for this to, for this condition to make sense, one needs this. First of all the we cannot ensure that the set of indices α is countable, let alone being finite. I mean if it is countable, at least one can interpret this as a series but α need not be a countable index. α is basically keeping track of how many charts covering the manifold. Well, but what one can ensure is.

(Refer Slide Time: 18:13)

So note that we can find a collection, a cover covering of M by charts which is locally finite i.e. if P is in M , I can find a neighborhood of P , let us call it U_P such that $U_P \cap U_\alpha$ is empty, except for finitely many α . So, in other words, if this is P , this is U_P which will intersect only finitely many U_α . So, in particular every P is contained in only finitely many U_α . So, once one has this, the moment you take and so here to interpret the last condition 3, if you take a specific x we know we note that we can find a covering of charts which is locally finite. So here of course, actually we already started with a system of oriented atlas.

So, what I need is that note that we can find a covering of M by, we can find a sub collection of U_α , the same U_α , which is a covering still a covering, sub collection meaning we can discard some of the original U_α s and which is locally finite. When I say note that, this still requires a proof, such that it is a topological argument and no time to go over it. So let us just assume it. So instead of saying note that, let me just say fact. Perhaps that is a better way of fact. We can find a sub collection of the U_α which is a covering and which is locally finite, we can find a neighborhood such that finitely many U_α .

Once we have this then every P is contained, so this becomes a finite sum the sum in part 3, because the P is contained in only finitely many U_α s and the support of ρ_α is in U_α . So, the moment this x is not in U_α , ρ_α will be 0. So, except for finitely many α s, all the $\rho_\alpha(x)$ will be 0. So, therefore, this makes sense. And in fact, this says that, not just at a specific x in a neighborhood U_P , also the same functions will survive and all the others will be 0.

(Refer Slide Time: 23:00)

Define $\omega = \sum_{\alpha} \rho_{\alpha} \varphi_{\alpha}^*(\omega_0).$

$\rho_{\alpha} \varphi_{\alpha}^*(\omega_0) \equiv 0$ outside $U_{\alpha}.$

$\omega|_{U_{\alpha}} = \sum_{\alpha} \rho_{\alpha}(x) \varphi_{\alpha}^*(\omega_0)$

Suppose $\rho_{\alpha}(x) = 0$ if $x \notin U_{\alpha_1}, \dots, U_{\alpha_k}$

$\omega|_{U_{\alpha}} = \rho_{\alpha}(x) (\varphi_{\alpha}^*(\omega_0)|_{U_{\alpha}}) + \dots + \rho_{\alpha_k}(x) (\varphi_{\alpha_k}^*(\omega_0)|_{U_{\alpha}}) \neq 0.$

$\varphi_{\alpha}^*(\omega_0) = c_{\alpha} \varphi_{\alpha}^*(\omega_0).$

$M, \{\rho_{\alpha}\}$ such that

- (1) $\text{Support of } \rho_{\alpha} \subseteq U_{\alpha}$
- (2) $0 \leq \rho_{\alpha}(x) \leq 1 \quad \forall x \in M.$
- (3) $\sum_{\alpha} \rho_{\alpha}(x) = 1.$

Fact! we can find a subcollection of $\{U_{\alpha}\}$ which is a cover and which is locally finite i.e. if $p \in M$, we can find a neighborhood of p , U_p such that $U_p \cap U_{\alpha} = \emptyset$, except for finitely many α . In particular, every p is contained in only finitely many U_{α} .

So, once we have this, then I can define our global form, define ω equal to $\rho_{\alpha} \varphi_{\alpha}^* \omega_0$. And now the point is that here, so this is $\rho_{\alpha} \varphi_{\alpha}^* \omega_0$ of course, this $\varphi_{\alpha}^* \omega_0$ is defined only on U_{α} but the support of ρ_{α} is a close set inside this, this is support of ρ_{α} and this is equal to, so what we do is we define it to be identically 0 outside the U_{α} . So elsewhere it is 0, on U_{α} , this is given by ρ_{α} , this is what this notation means. It is understood that this thing is identically 0 outside. So, each term makes sense and then we, as a global form on M and then we add it all up.

The thing is that this is, now all one has to do is check that this is nowhere vanishing. So if I take a specific P , so rather $x \in M$ at x is $\rho_{\alpha}(x)$ and then this. Now, because of this

partition of unity condition, only finitely many alphas will survive for which this $\rho_\alpha x$ is not 0, suppose $\rho_\alpha x$ is equal to 0 if α is not equal to one of these finitely many, this is then ω_x will be $\rho_{\alpha_1} \star \phi_{\alpha_1}^{-1} \star \omega_{\alpha_1}$ etcetera, $\phi_{\alpha_k} \star \omega_{\alpha_k}$. Well, that is we still have not used the condition that we started with an oriented atlas. I could have done all this starting with any atlas.

Now the last step is to say that this is not 0 at any x . And here is where we use the oriented atlas condition. So, basically what I will claim, essentially I just want to relate $\phi_{\alpha_1} \star \omega_{\alpha_1}$. Of course, this entire thing evaluated at x , everything at x , etcetera. So $\phi_{\alpha_1} \star \omega_{\alpha_1}$, we know that any 2 n forms, multiples of each other at a specific point. So if I fix x , then this is some constant times, let us call it C_1 times. Actually, let us use $\phi_{\alpha_1} \star \omega_{\alpha_1}$ as the base. So let me start with 2 onwards. So I want to compare everything else in terms of $\phi_{\alpha_1} \star \omega_{\alpha_1}$ and then α_2 is let us call it $C_2 \phi_{\alpha_1} \star \omega_{\alpha_1}$.

(Refer Slide Time: 27:50)

The image shows a digital whiteboard with handwritten mathematical derivations. The top section starts with the assumption $\rho_\alpha(x) = 0$ if $\alpha \neq \alpha_1, \dots, \alpha_k$. It then defines $\omega_x = \rho_{\alpha_1}(x) (\phi_{\alpha_1}^*) (\omega_{\alpha_1}) + \dots + \rho_{\alpha_k}(x) (\phi_{\alpha_k}^*) (\omega_{\alpha_k})$ and notes $\neq 0$. This is equated to $\rho_{\alpha_1}(x) (\phi_{\alpha_1}^*) \omega_{\alpha_1} + C_2 \rho_{\alpha_2}(x) (\phi_{\alpha_2}^*) \omega_{\alpha_2} + \dots$. The bottom section shows the transformation of $\phi_{\alpha_2}^* (\omega_{\alpha_2})$ using the transition function $\phi_{\alpha_1}^{-1} \circ \phi_{\alpha_2}$, resulting in $\phi_{\alpha_1}^* (\phi_{\alpha_1}^{-1} \circ \phi_{\alpha_2})^* (\omega_{\alpha_2}) = (\phi_{\alpha_1}^{-1} \circ \phi_{\alpha_2})^* (\omega_{\alpha_2}) = \phi_{\alpha_2}^* (\omega_{\alpha_2})$. The final result is $\phi_{\alpha_2}^* (\omega_{\alpha_2}) = \left(\rho_{\alpha_1}(x) + C_2 \rho_{\alpha_2}(x) + \dots + C_k \rho_{\alpha_k}(x) \right) \phi_{\alpha_1}^* (\omega_{\alpha_1})$.

And here is the main point, the fact that it is oriented charts will imply that the C_2 is positive, because after all, what is C_2 is positive because C_2 , I can, to figure out what C_2 is, just rewrite it like this, the usual thing of using a transition function. So, essentially I throw in the inverse of this and then this and then $\phi_{\alpha_1} \star \omega_{\alpha_1}$ then I take the inverse inside and so on and star outside and then finally I will get $\phi_{\alpha_1}^{-1} \circ \phi_{\alpha_2}$ whole thing star and then $\phi_{\alpha_1} \star \omega_{\alpha_1}$. That is assuming that α_1 , this U_{α_1} and U_{α_2} intersect, they I mean if x is, if $\rho_\alpha x$ is not 0, then they have to intersect.

So, I get it like this and therefore, and as we have seen many times, when I pull back by the, and here is the star means the derivative and so on. Here, it is not quite the transition function, but it is the sort of reverse of the transition function. But at any rate, what will play a role is the derivative, the determinant of the derivative of this will come into play. Then using the fact that transition functions are positive, then one can prove that this determinant is also positive. Ultimately, so one end up getting this. So, you have an expression like this. Yeah. So, the first term I keep it as it is $\phi^1 \star \omega_0 + C_2 \text{ times } \rho^2 \times \phi^1$, again the same term and so on.

So, finally, I will end up with this plus $C_2 \rho^2 \times \dots$ plus $C_k \rho^k \times$, whole thing multiplied by, well $\rho^1 \star \omega_0$. Now, the point is that since this is a summation of the ρ alphas is 1, at least 1 of these ρ^1 , ρ^2 should be positive and the C 's are already positive. And all the ρ alphas are non-negative, so therefore the whole, the entire sum should be strictly positive. So therefore, this is not 0. It is just a possible positive multiple of this. So this completes the brief sketch and we will stop the course at this point. As I said one would then next talk about integration on manifolds and after introducing manifolds with boundary and then finally move on to Stokes theorem.

And when the whole theory of differential forms is crucial for even to talk about integration on manifolds. So thank you. So we will end the course at this point. A natural starting point for subsequent study will be a little bit more about orientation, examples and so on. And then one can read some material about manifolds with boundary, then integration on manifolds. Then finally, one will have Stokes theorem on manifolds, which is a very useful tool and generalizes all the classical Stokes theorem in \mathbb{R}^3 , Green's theorem in \mathbb{R}^2 and so on. So, thank you.
