Indian Institute of Science, Bengaluru
Lecture- 14
Measure Theory

So, next we will look at properties of the outer measure. So, recall that we just defined the outer measure on subsets of \mathbb{R}^n , for each subset of \mathbb{R}^n we have a positive number associated to it. It may be 0 or a positive number or it could be infinity also and this outer measure is supposed to give us a countably additive measure, when we restricted to an appropriate sigma algebra that will come later. Before that, so towards to move towards such a goal, we look at basic properties of the outer measure we just defined.

(Refer Slide Time: 01:13)

So, let us recall that so properties of outer measure, so will keep this in the side. So, m^* of E was defined to be the infimum of certain quantities this is summation mod Q_j , j equal to 1 to infinity, Q_j were closed cubes and it was a cover of E . So, you cover E with closed cubes form this quantity and take the infimum. So, Properties of outer measure the first one, this is monotonicity we just saw this, so I will be brief here monotonicity, if A is content in B then m^* of A is less than or equal to m^* of B .

So, this immediately so this we saw earlier so this immediately implies that m^* of the whole space \mathbb{R}^n is infinity because you can take any take big cubes. Q content in \mathbb{R}^n and that will become bigger and bigger because if Q is content in \mathbb{R}^n , m^* of Q is less than or equal to m^* of \mathbb{R}^n , but m^* of Q is simply the volume of Q

and the volume of Q can be made as big as you want, so that is easy. Second one, second property this is called Subadditivity. Subadditivity again a very natural property to have a new look at measures and so on.

So, if E is equal to union E_j , j equal to 1 to infinity, then m^* of E is less than or equal summation j equal to 1 to infinity m^* of E_j this is called subadditivity. The volume of E so imagine these are all cubes then volume of E will be less than or equal to sum of volumes of E_j because E_j 's may overlap. So, that is what is reflected here and it is true for all sets so that is the important point. Let us prove this, so we start with assuming that we assume that m^* of E_j is finite for every E_j . Otherwise, the right hand side will have an infinity and then this otherwise this is trivial because the right hand side will have an infinity term and then we have the inequality clearly.

Now, m^* of E_j is finite, so there exist the covering so there exist a covering so this is what I had mentioned as soon as the definition of m^* was introduced because it is the infimum for every epsilon you have a covering with certain property. So, there exist the covering of E_j so E_j content in Q , well notation has to be clear Q_{kj} , union k equal to 1 to infinity. What are Q_{kj} is? Q_{kj} are these are closed cubes so, for each j I have Q_{kj} 's and summation k equal to 1 to infinity modulus of Q_{kj} is less than or equal to m^* of E_j plus epsilon by 2 to the j .

So, of course we always start with an epsilon so maybe I should have said that first so let us put this here. Fix epsilon positive, so there exist the covering of E_j such that this happens. This is just the property of infimum, the epsilon by 2 to the j is a positive number so I will have a covering with this property. So, keep that property, keep that inequality in mind because that is something which will you use.

(Refer Slide Time: 6:32)

$k=1$
 $\hookrightarrow \emptyset$

Now we have $E \subseteq \bigcup_{k=1}^{\infty} Q_{k,j}$ $m_*(E)$ is the inf of ...
 Hence $m_*(E) \leq \sum_{k=1}^{\infty} |Q_{k,j}|$ \hookrightarrow Cov of E by closed cubes

$$\begin{aligned}
 &= \sum_{k=1}^{\infty} \left(\sum_{j=1}^{\infty} |Q_{k,j}| \right) \leq \sum_{k=1}^{\infty} \left(m_*(E_j) + \frac{\epsilon}{2^k} \right) \\
 &= \sum_{k=1}^{\infty} m_*(E_j) + \sum_{k=1}^{\infty} \frac{\epsilon}{2^k} \\
 \Rightarrow m_*(E) &\leq \sum_{j=1}^{\infty} m_*(E_j)
 \end{aligned}$$

Properties of outer measure

(I) (Monotonicity) if $A \subseteq B$ then $m_*(A) \leq m_*(B)$

(II) (Sub additivity) if $E = \bigcup_{j=1}^{\infty} E_j$ then $m_*(E) \leq \sum_{j=1}^{\infty} m_*(E_j)$

For $\epsilon > 0$ We assume that $m_*(E_j) < \infty + \epsilon_j$ (otherwise is trivial)

\exists a covering of E_j by $\{Q_{k,j}\}_{k=1}^{\infty}$ (finite of cubes)

N and $\sum_{k=1}^{\infty} |Q_{k,j}| \leq m_*(E_j) + \frac{\epsilon}{2^j}$

$\hookrightarrow \emptyset$

$$\begin{aligned}
 &= \sum_{k=1}^{\infty} \left(\sum_{j=1}^{\infty} |Q_{k,j}| \right) \leq \sum_{k=1}^{\infty} \left(m_*(E_j) + \frac{\epsilon}{2^j} \right) \\
 &= \sum_{j=1}^{\infty} m_*(E_j) + \sum_{k=1}^{\infty} \frac{\epsilon}{2^k} \\
 \Rightarrow m_*(E) &\leq \sum_{j=1}^{\infty} m_*(E_j)
 \end{aligned}$$

(This argument, $\frac{\epsilon}{2^j}$ -argument will be used again and again)

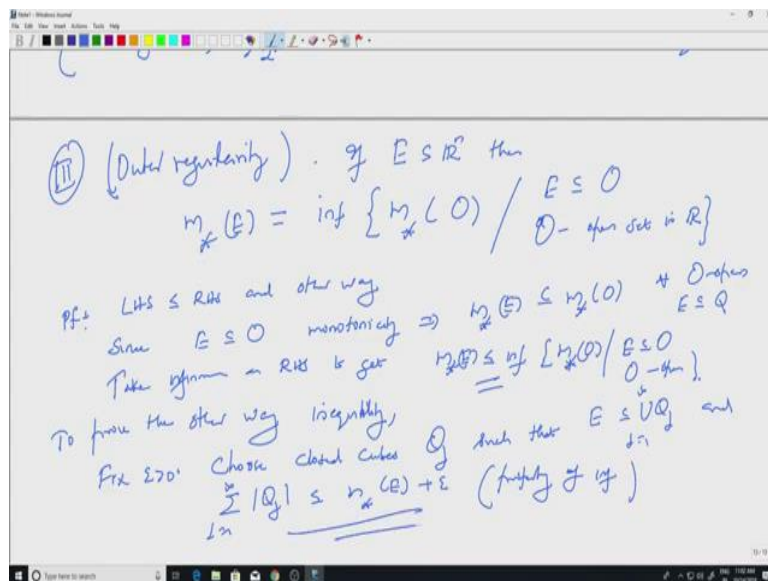

Q_k is cover E_j and E_j is cover E , so by put together I will get so now we have E content in union union Q_k , k equal to 1 to infinity, j equal to 1 to infinity because of this property and E is the simply the union of E_j .

So, hence m^* of E remember m^* of E is the infimum, m^* of E is the infimum of certain quantities and this is a cover of E by closed cubes. So, by sum of mod Q_k 's that would be a number in the set where we take the infimum of. So, m^* of E will be less than or equal to summation Q_k , k equal to 1 to infinity, j equal to 1 to infinity. But, this is less than or equal to so let me write a one more time so that this is clear, so this is nothing but summation j equal to 1 to infinity, summation k equal to 1 to infinity, mod Q_k , but, this quantity is less than or equal to, so we chose those covers with some property right.

So, this is results with j equal to 1 to infinity, m^* of E_j plus epsilon by 2 to the j . so, that is how remember this is we chose it, one so this is by one which is simply summation j equal to 1 to infinity, m^* of E_j plus epsilon. So, we have m^* of E less than or equal to m^* of summation of m^* of E_j plus epsilon for every epsilon positive. So, I can let epsilon go to 0 so to get m^* of E less than or equal to summation j equal to 1 to infinity m^* of E_j which is the subadditivity property.

So, if E is the union of countably many sets we will have this subadditivity property. So, this argument that something we will use again and again, so let us let me give it a name so this argument so will call it, the epsilon by 2 to the j argument will be used again and again so, this is something you should understand very clearly. So, we have two properties, Monotonicity and we have a Subadditivity.

(Refer Slide Time: 9:55)

Next one another important property third property, this is called Outer regularity. What does that say? If E is a subset of \mathbb{R}^n , then m^* of E is equal to infimum of well it is not the definition, it is going to be m^* of O , what is O ? O is an open set, E is content in O , open set in \mathbb{R}^n .

So, you look at all the open sets containing E , look at m^* of all those open sets, take the infimum that is what m^* of E is. So, remember that this is very surprising but at the same time it is an extremely important property. How you will prove this? So as usual we want to prove two things are equal, so we use the inequalities so will show that, LHS is less than or equal to RHS and RHS is less than or equal to. So, will show that LHS is less than or equal to RHS and vice versa and the other way, so then both of them will be equal.

So, as usual one of the inequalities will be easy so since E is content in O , monotonicity will tell me, monotonicity implies that m^* of E is content in m^* of O , O open set. But, this is true for every open set containing E , so I can take infimum on the right hand side so, take infimum on the right hand side to get m^* of E is less than or equal to infimum of m^* of O , such that E is content in O and O open, this is what we want. So, we have one-way inequality, we want to prove the other way. So, to prove the other way, other way inequality choose so you will see the epsilon by 2 to the j argument coming again and again.

So, let us start with fixing epsilon etc. etc. so fix epsilon positive. Choose closed cubes Q_j such that E is content in union Q_j , j equal one to infinity of course that is possible and summation mod Q_j , j equal to 1 to infinity is less than or equal to m^* of E plus epsilon. This is possible this is simply the property of infimum. That is the first thing I mentioned

after defining the outer measure, property of infimum. So given epsilon I can get a cover with this property satisfied.

(Refer Slide Time: 14:13)

For each Q_j choose open cube S_j such that $Q_j \subseteq S_j$ and

$$|S_j| \leq |Q_j| + \frac{\epsilon}{2^j}$$

Let $O = \bigcup S_j$ — open set

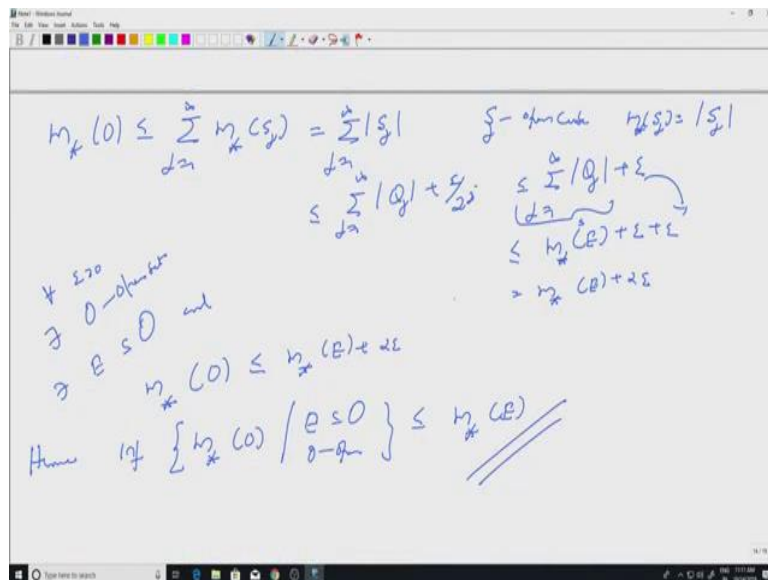

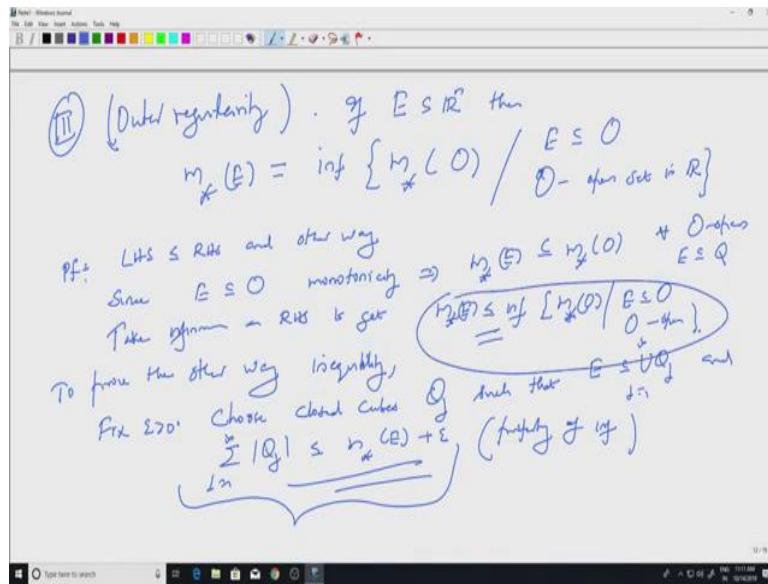

and $E \subseteq \bigcup_{j=1}^{\infty} Q_j \subseteq \bigcup_{j=1}^{\infty} S_j = O$

$|S_j| \leq |Q_j| + \frac{\epsilon}{2^j}$

Let $O = \bigcup S_j$ — open set

and $E \subseteq \bigcup_{j=1}^{\infty} Q_j \subseteq \bigcup_{j=1}^{\infty} S_j = O$

$m_*(O) \leq \sum_{j=1}^{\infty} m_*(S_j)$ (by subadditivity)

What do we do with this closed cubes? So for each Q_j choose an open cube, open cube S_j such that Q_j is content in S_j well that is easy.

But, we have the epsilon estimate there so we need to do appropriate, we need to choose appropriate S_j such that the volume of S_j is very close to the volume of Q_j . So, mod Q_j plus epsilon by 2 to the j , so remember epsilon by 2 to the j is a positive number so all I have to do is to slightly enlarge Q_j . If this is my Q_j I choose my S_j very closed to it, so that so this is Q_j and this would be S_j . Only thing is this inequality should be true so, you enlarge Q_j slightly, this is possible, but now these are open cubes so I have an opened set, so let O be equal to union S_j , j equal to 1 to infinity, this is an open set because the union of open cubes and so it is an open set.

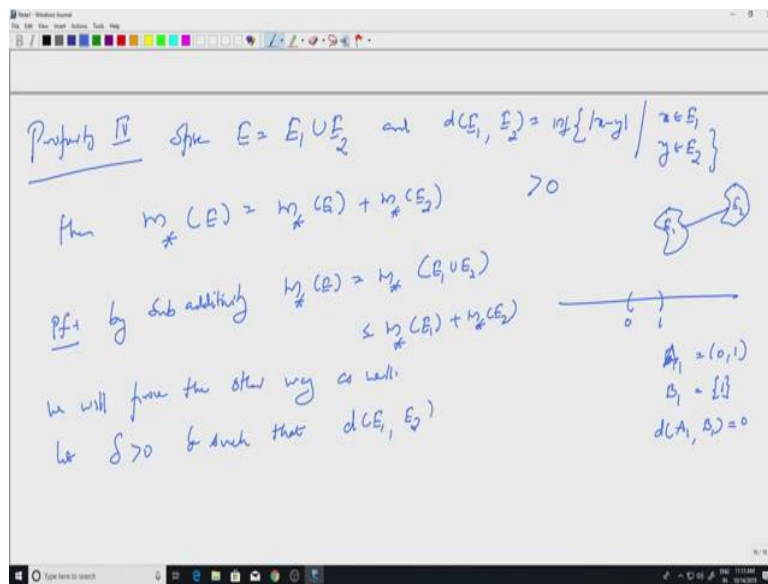

And the set E is content in well I know it is content in union Q_j , j equal to 1 to infinity but surely content in union S_j , now j equal to 1 to infinity which is my open set O . So, what I have done is getting an open set O which is slightly bigger than the union Q_j , so O is the union of things, union of S_j . So, m^* of O will be less than or equal to summation j equal to 1 to infinity, m^* of S_j this is by subadditivity. So, we have m^* of O less than or equal to summation of J equal to 1 to infinity, m^* of S_j which is equal to summation j equal to 1 to infinity, m^* of S_j because S_j is a open cube.

So, m^* of S_j will be the volume of S_j which is less than or equal to because the way as j are chosen we have j equal to 1 to infinity, m^* of Q_j plus epsilon by 2^j which is less than to summation, j equal to 1 to infinity m^* of Q_j which is less than or equal to m^* of E plus epsilon. So, this portion is less than or equal to m^* of E plus epsilon and there is another epsilon. So, this is nothing but m^* of E plus 2 epsilon, the 2 epsilon does not matter because epsilon is arbitrary epsilon.

So, what we have done is for every epsilon positive there exist O open set such that E is content in O and m^* of O is less than or equal to m^* of E plus 2 epsilon. This is true for every open set for every epsilon, hence I can take the infimum on the left hand side and let epsilon go to 0. So, infimum of all m^* of O where E is content in O , O open this is less than or equal to m^* of E , so we have the other way inequality. So, this is one inequality and the first one we started with that is the trivial part this portion.

So, we have the both way inequalities and so we have proved outer regularity, so will stop with one more property.

(Refer Slide Time: 19:02)

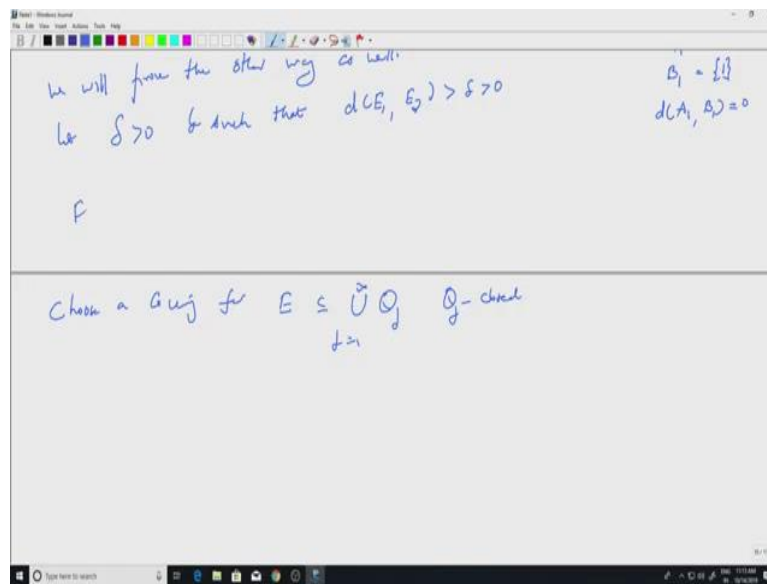

So, property 4 this is some kind of additivity but with some strong conditions. Suppose E is a union of two things, E1 union E2 two sets and distance between E1 and E2, so what is distance between E1 and E2? So, this is the infimum of modulus of x minus y where x belongs to E1 and y belongs to E2 so, that is the distance between the two sets E1 and E2. Suppose this is greater than 0, so they are not just disjoint they are at a distance so this could be E1 and E2 could be somewhere here. There is a distance between them, this is positive.

Then we have additivity for the outer measure then m star of E equal to m star of E1 plus m star of E2, we want countably additivity so this is a much weaker property that if I have E1 and E2 at a distance then the outer measure adds up. So, let us prove this so E1 and E2 are disjoint but disjoint does not mean that the distance between them is greater than 0. For example, I may have an open interval like (0, 1), E1 could be or let us say A1, A1 is open interval (0, 1) and B1 could be the singleton 1.

Then the distance between A1 and B1 is actually equal to 0 because 1 is in the boundary of A1. So disjoint does not mean distance is positive but, distance positive would surely imply that they are disjoint. So, first of all by subadditivity, we have m star of E is equal to m star of E1 union E2 by subadditivity this is less than or equal to the outer measure of each component. We proved it for infinite 1 but that is the same one for finite unions. So, we have one-way inequality, so we will prove the other way, we will prove the other way inequality as well, so let us prove that.

(Refer Slide Time: 22:26)

So, let delta positive be such that, the distance between E_1 and E_2 is greater than delta. So, choose a covering for E , so E is content in union Q_j , j equal to 1 to infinity, Q_j closed cubes. Then we summed up mod Q_j then take the infimum to get the m star of E , such that so again usually there is an epsilon so first fix an epsilon. Fix epsilon positive, choose a covering for E such that, E is content in thus and summation mod Q_j , j equal to 1 to infinity is less than or equal to m star of E plus epsilon. So, this we have seen this several times, now this is simply the property of infimum.

So, now if possible so let us perhaps draw picture so that it is sort of clear so I have E_1 here, I have E_2 here and E is the union of these two. So, I am covering E with cubes like this and so on, but some cubes were intersect both of them, it can be bigger cubes like this. So, what you do is subdivide such ones, so subdivide each Q_j if necessary, so that diameter of Q_j is less than delta. Then so what is the point recall that E_1 and E_2 are at a distance delta so I have E_1 here, I have E_2 here and the distance between them is delta.

So, if I take a cube of diameter less than delta then if intersects E_1 it cannot intersect E_2 , so each Q_j then will intersect only one of E_1 or E_2 . Only one of the E_j is it can intersect, it cannot intersect both of them because, the distance between them is delta so if the cube intersects both of them the diameter of the cube will be greater than or equal to delta but, we have chosen, we have subdivided Q_j so that it is less than that. So, let us write J_1 to be although in this is J , such that Q_j intersects E_1 and J_2 to be although intersects all those in this is K such that Q_k intersects E_2 .

So, J_1 and J_2 are disjoint because if there is a common index then that particular Q_j will have to intersect both E_1 and E_2 which is not possible.

(Refer Slide Time: 22:56)

Choose a $\delta > 0$ for $E \subseteq \bigcup_{j=1}^{\infty} Q_j$ Q_j -closed and $\sum_{j=1}^{\infty} |Q_j| \leq M_2 \epsilon + \epsilon$

Sub divide each Q_j (if necessary) so that $\text{diameter}(Q_j) < \delta$. Each Q_j then will intersect only one of E_1 or E_2

$J_1 = \{j / Q_j \text{ intersects } E_1\}$ J_1 and J_2 are disjoint

$J_2 = \{k / Q_k \text{ " " " } E_2\}$

We will prove the other way as well.

Let $\delta > 0$ be such that $d(E_1, E_2) > \delta > 0$

Fix $\epsilon > 0$

$M_1 = 1/\delta$
 $B_1 = \mathbb{R}^n$
 $d(A_1, A_2) = 0$

Choose a $\delta > 0$ for $E \subseteq \bigcup_{j=1}^{\infty} Q_j$ Q_j -closed and $\sum_{j=1}^{\infty} |Q_j| \leq M_2 \epsilon + \epsilon$

Sub divide each Q_j (if necessary) so that $\text{diameter}(Q_j) < \delta$. Each Q_j then will intersect only one of E_1 or E_2

$J_1 = \{j / Q_j \text{ intersects } E_1\}$ J_1 and J_2 are disjoint

$J_2 = \{k / Q_k \text{ " " " } E_2\}$

Work $E = E_1 \cup E_2$

$$E_1 \subseteq \bigcup_{I \in \mathcal{J}_1} Q_I \quad E_2 \subseteq \bigcup_{I \in \mathcal{J}_2} Q_I$$

Hence $m_*^*(E_1) + m_*^*(E_2) \leq \sum_{I \in \mathcal{J}_1} |Q_I| + \sum_{I \in \mathcal{J}_2} |Q_I| \leq \sum_{I \in \mathcal{J}} |Q_I| \leq m_*^*(E) + \epsilon$

$\Rightarrow m_*^*(E_1) + m_*^*(E_2) \leq m_*^*(E)$

Property II Since $E = E_1 \cup E_2$ and $m_*^*(E_1) = m_*^*(E_2) = 0$

Hence $m_*^*(E) = m_*^*(E_1) + m_*^*(E_2) = 0$

Pf: by sub additivity $m_*^*(E) = m_*^*(E_1 \cup E_2) \leq m_*^*(E_1) + m_*^*(E_2) = 0$

We will prove the other way as well.
 Let $\delta > 0$ be such that $d(E_1, E_2) > \delta > 0$

Fix $\epsilon > 0$

Choose a Gubj for $E \subseteq \bigcup Q_i$ Q_i -closed and $\sum |Q_i| \leq m_*^*(E) + \epsilon$

Hence $m_*^*(E_1) + m_*^*(E_2) \leq \sum_{I \in \mathcal{J}_1} |Q_I| + \sum_{I \in \mathcal{J}_2} |Q_I| \leq \sum_{I \in \mathcal{J}} |Q_I| \leq m_*^*(E) + \epsilon$

$\Rightarrow m_*^*(E_1) + m_*^*(E_2) \leq m_*^*(E)$

Hence

So, I can write E , I will remember this is $E_1 \cup E_2$ to be said E_1 is content in union Q_j , j in J_1 and E_2 is content in union Q_j , j in J_2 because I put together I will cover E , the ones which intersect E_1 will cover E_1 and the ones which intersect E_2 will cover E_2 , they are disjoint, they are far apart.

So, because of this hence m^* of E_1 plus m^* of E_2 is less than or equal to so look at this, this is one covering of E so this is one covering of E . Definition of m^* of E , what do you do? You look at summation $\sum_{j \in J} \text{mod } Q_j$ where j belongs to J_1 and then the infimum. So, m^* of E_1 will be less than or equal to summation $\sum_{j \in J_1} \text{mod } Q_j$ and similarly, m^* of E_2 will be less than or equal to summation $\sum_{j \in J_2} \text{mod } Q_j$, but, J_1, J_2 are disjoint, I can put together so this is less than or equal to summation $\sum_{j=1}^{\infty} \text{mod } Q_j$, all the Q_j 's.

But, the Q_j 's were chosen so that they were at an epsilon distance from m^* of E so this is less than or equal to m^* of E plus epsilon. Remember that is how the Q_j is were chosen so we had chosen Q_j is to be with property. So, what did we prove, we proved that m^* of E_1 plus m^* of E_2 is less than or equal to m^* of E plus epsilon. This is true for every epsilon velocity. So, this will imply that m^* of E_1 plus m^* of E_2 is less than or equal to m^* of E , so that is one inequality. The other way was easy because of subadditivity. So, by subadditivity we have the other way inequality so this tells me that, they are equal, hence they are equal.

So will stop with this, hence we have m^* of $E_1 \cup E_2$ equal to m^* of E_1 plus m^* of E_2 . So, remember the strong condition we have provided the distance between E_1 and E_2 is greater than delta or positive so that is enough it is positive, that is an extra condition. So, we will stop with this so what we have seen in this lectures is the definition of outer measure and it is defined for all subsets of \mathbb{R}^n . And we saw some properties, monotonicity, subadditivity and outer regularity along with additivity property is the sets are disjoint and at a distance greater than 0.

That is very weaker than countably additivity, so in the next lectures we will restrict the outer measure to a sigma algebra called the Lebesgue sigma algebra and will prove that, it is actually countably additive in that sigma algebra. So, that will complete the construction of the Lebesgue measure on \mathbb{R} .
