**Lebesgue measurable sets and Lebesgue measure on  $\mathbb{R}^n$**

So, in the last lecture we saw the outer measure. Outer measure is a quantity which is defined on all subsets of  $\mathbb{R}^n$ . It has some interesting properties, we saw some of them in the last lecture. One was the monotonicity which is a trivial property, second was sub-additivity, countable sub-additivity, third was the outer regularity and fourth was an interesting property which said that if two sets are at a distance positive distance, so not just disjoint, they are at a distance, then the outer measure will add up.

So, outer measure is defined on the power set of  $\mathbb{R}^n$ , it is not going to be a countably additive measure on the power set, we will have to find a collection of subsets of  $\mathbb{R}^n$  which will be called the Lebesgue sigma algebra on which this outer measure, the restriction of the outer measure to the Lebesgue sigma algebra will be countably additive measure. So, that is our aim in this lecture and the next lecture.

By next lecture, we should be able to complete the construction of the Lebesgue measure. So, we will start with recalling some of the things we did in the last lecture.

(Refer Slide Time: 01:57)

Let us start, so recall outer measure. So, this was denoted by  $m_*$  and  $m_*$  of a set  $E$  this was equal to the infimum of summation mod  $Q_j$ ,  $j$  equal to 1 to infinity where  $E$  was contained in  $Q_j$ . So,  $Q_j$  form a cover of  $E$  and  $Q_j$  were closed cubes.

So, let me repeat that one needs the infinite collection here, just taking finite union of cubes will not work that will not give us a genuine countably additive measure. So, this was the outer measure and we had some properties. So, let me recall those properties, so properties which we proved in the last class so one was monotonicity; monotonicity, what was that? If  $A$  is contained in  $B$  that implies the outer measure of  $A$  is less than or equal to outer measure of  $B$ .

So, that is that was easy, so, outer measure you should think of as the size of the set. So, the set is bigger the size should be bigger, that is what was proved yesterday. Second one, this was countable sub additivity, sub additivity. So, this said that, if I write  $E$  as union  $E_j$ ,  $j$  equal to 1 to infinity, then the outer measure of  $E$  is less than or equal to the sum of the outer measure of individual  $E_j$ 's.

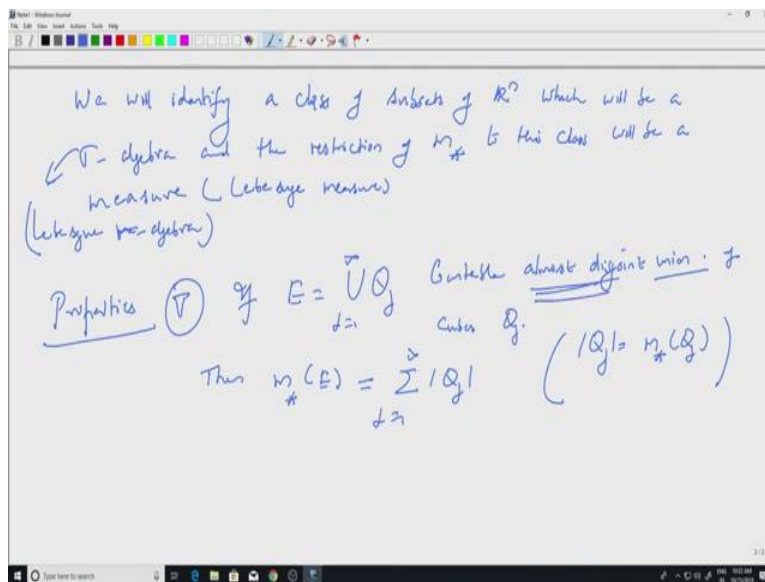

So, when you take the union well, because the  $E_j$ 's may not be disjointed, even if  $E_j$ 's are disjointed, we do not know if they add up, but sub additivity is something which we can prove. Third one was outer regularity, this is an important property out of regularity, this was  $m_*$  of  $E$  so the outer measure of any set  $E$  is the infimum of  $m_*$  of  $O$  open sets. So,  $O$  was an open

set, open subset of  $\mathbb{R}^n$  and more importantly,  $E$  was contained in  $O$ , so, you look at all open sets bigger than  $E$  and look at the size of them using  $m^*$  and take the infimum that will give me  $m^*$  of  $E$ , and this is again to for all subsets  $E$ .

The fourth one we proved was, if the distance between two sets  $E_1$  and  $E_2$  is greater than 0, then so that means they are at a distance, so they are not just disjoint, they are at a distance, then the outer measure adds up. So,  $m^*$  of  $E_1 \cup E_2$  this is equal to  $m^*$  of  $E_1$  plus  $m^*$  of  $E_2$ . So, we would like countable additivity, this is not countable additivity, this is only finite additivity for sets with this condition.

So that is a much weaker than whatever we want, but this is true for every  $E_1$  and  $E_2$  which is a subset of  $\mathbb{R}^n$ . So, this is the property is on a larger, rather large class of sets. So, our aim would be to restrict.

(Refer Slide Time: 6:03)

So, aim will be to restrict the outer measure. So, let me see, so, we will, we will identify a class of subsets, of  $\mathbb{R}^n$  which will be a sigma algebra, and the restriction, restriction of  $m^*$  to this class will be a measure, countably additive measure.

So, this is called the Lebesgue measure, Lebesgue measure and sigma algebra will be called the Lebesgue sigma algebra. This is going to be a rather rich class of sets, we will see soon, but before that let us continue with the property. So, we had four properties, we will look at the fifth one, which is more or less like countable additivity.

So, property we are continuing with outer measure, we are looking at the fifth property of the outer measure. So, we write  $E$  has a countable union of cubes. So, countable, almost disjoint almost. So, this is of close cubes almost disjoint union of cubes, cubes  $Q_j$ . Then we have additivity, so, then  $m^*$  of  $E$  so remember this is going to be the Lebesgue measure of  $E$ , later on if  $E$  is a nice enough set which we will identify, but in this particular case when  $E$  is actually countable disjoint union of cubes then the outer measure of  $E$  is summation mod  $Q_j$ .

So, remember the four cubes we know that this is the outer measure. So, we are saying our measure of union of  $Q$  days is the sum if they are almost disjoint. So, let us let us try to prove that, so let us keep this statement here.

(Refer Slide Time: 9:03)

Pf: We will show that  $m^*(E) \leq \sum_{j=1}^{\infty} |Q_j|$  and  $\sum_{j=1}^{\infty} |Q_j| \leq m^*(E)$

Sub additivity we have  $m^*(E) \leq \sum_{j=1}^{\infty} m^*(Q_j) = \sum_{j=1}^{\infty} |Q_j|$

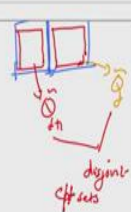

Fix  $\epsilon > 0$ . Let  $\tilde{Q}_j$  be a cube strictly contained in  $Q_j$  and  $|Q_j| \leq |\tilde{Q}_j| + \frac{\epsilon}{2^j}$

$\tilde{Q}_j$  are disjoint, compact sets.  $d(Q_j, \tilde{Q}_k) > 0$

(Ex:  $(X, d)$  metric space.  $A, B$  cft sets in  $X$ .  $A \cap B = \emptyset$ .)

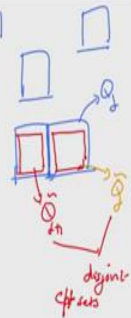

The diagram shows a large cube  $Q$  containing several smaller, disjoint cubes  $\tilde{Q}_j$ . Arrows indicate the relationship between the large cube and the smaller ones. A note says "disjoint cft sets".

strictly contained in  $Q_j$  and  $|Q_j| \leq |Q_j| / 2^j$   
 $\tilde{Q}_j$  are disjoint, compact sets.  $d(\tilde{Q}_j, \tilde{Q}_k) > 0$   
 (Exct) (X d) metric space.  $A, B$  ctt sets in  $X$   
 $A \cap B = \emptyset$ . Then  $d(A, B) > 0$   
 $\Leftrightarrow \exists \epsilon > 0 \{d(x, y) \mid x \in A, y \in B\}$

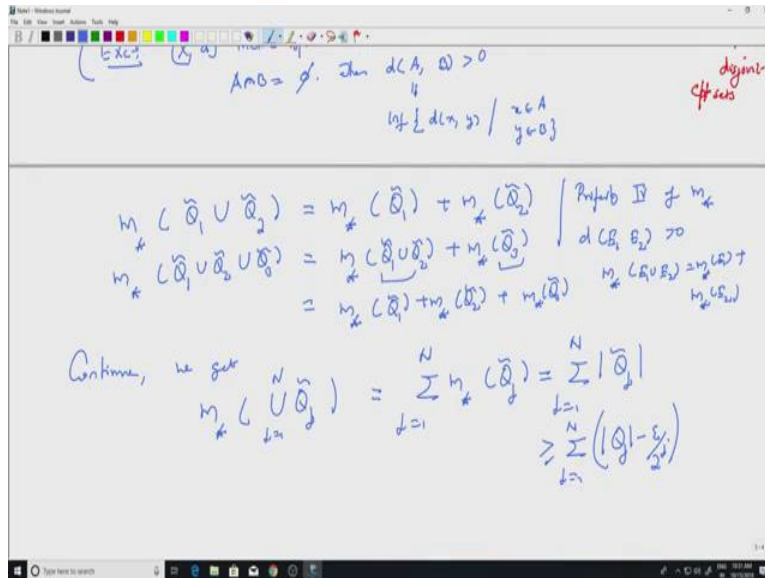

$m_*(\tilde{Q}_1 \cup \tilde{Q}_2) = m_*(\tilde{Q}_1) + m_*(\tilde{Q}_2)$  | Property II of  $m_*$   
 $m_*(\tilde{Q}_1 \cup \tilde{Q}_2 \cup \tilde{Q}_3) = m_*(\tilde{Q}_1 \cup \tilde{Q}_2) + m_*(\tilde{Q}_3)$  |  $d(B_1, B_2) > 0$   
 $= m_*(\tilde{Q}_1) + m_*(\tilde{Q}_2) + m_*(\tilde{Q}_3)$  |  $m_*(A \cup B) = m_*(A) + m_*(B)$

Subadditivity we have  $m_*(E) \leq \sum_{j=1}^{\infty} m_*(Q_j) = \sum_{j=1}^{\infty} |Q_j|$   
 Fix  $\epsilon > 0$ . Let  $\tilde{Q}_j$  be a cube  
 strictly contained in  $Q_j$  and  $|Q_j| \leq |\tilde{Q}_j| + \epsilon/2^j$   
 $\tilde{Q}_j$  are disjoint, compact sets.  $d(\tilde{Q}_j, \tilde{Q}_k) > 0$   
 (Exct) (X d) metric space.  $A, B$  ctt sets in  $X$   
 $A \cap B = \emptyset$ . Then  $d(A, B) > 0$   
 $\Leftrightarrow \exists \epsilon > 0 \{d(x, y) \mid x \in A, y \in B\}$

$m_*(\tilde{Q}_1 \cup \tilde{Q}_2) = m_*(\tilde{Q}_1) + m_*(\tilde{Q}_2)$  | Property II of  $m_*$   
 $m_*(\tilde{Q}_1 \cup \tilde{Q}_2 \cup \tilde{Q}_3) = m_*(\tilde{Q}_1 \cup \tilde{Q}_2) + m_*(\tilde{Q}_3)$  |  $d(B_1, B_2) > 0$   
 $= m_*(\tilde{Q}_1) + m_*(\tilde{Q}_2) + m_*(\tilde{Q}_3)$  |  $m_*(A \cup B) = m_*(A) + m_*(B)$

So, we will let start with the proof. So, proof as usual, one will prove inequalities, so, we will prove that so we will show that  $m^*$  of  $E$ ,  $E$  remember is a is accountable almost disjoint union of cubes is less than or equal to summation mod  $Q_j$ , mod  $Q_j$  and summation mod  $Q_j$  is less than or equal to the outer measure of  $E$ .

So, once we have both these inequalities, they will have to be equal. So, that is the usual strategy of proof in, in this topics. So, let us start so, so first of all first of all this part is easy, that is simply countable additivity, by sub-additivity we have  $m^*$  of  $E$  to be less than or equal to summation  $j$  equal to 1 to infinity  $m^*$  of  $E_j$  sorry  $Q_j$ ,  $Q_j$  but  $m^*$  of  $Q_j$  we know that it is the volume of the cubes.

So, for cubes we already know this, so, this we have, so that is one inequality, so this this is done. So, we have to show this one, this is the non trivial part. So as usual  $\epsilon$  and epsilon, so by now, you must have seen this epsilon by 2 to the  $J$  argument several times so we use something very similar, but we also use some of the properties of  $m^*$  which we proved earlier.

So, let  $\epsilon$  be positive, so let  $Q_j$  tilde be a cube, strictly contained in,  $Q_j$ . So maybe we will draw some pictures to see what it is, so remember the  $Q_j$  are almost is disjoint. So, either they can be disjoint so, you may have a cube here, you may have a cube here, or you may have a cube here and you have a cube here. So, they may be intersecting at the boundary, but that is okay the interiors are going to be disjoint.

So,  $Q_j$  tilde is a cube strictly contained in  $Q_j$ . So, let us see, so  $Q_j$  tilde will be something like this, we will, specify the condition with respect to which  $Q_j$  tilde should be chosen. So, the outside ones are  $Q_j$  and let us denote this, who these ones are  $Q_j$  and the inside ones are  $Q_j$  tilde. Well how do we choose them? So contained in  $Q_j$  and mod of  $Q_j$  tilda or  $Q_j$  is less than or equal to mod of  $Q_j$  tilde plus epsilon by 2 to the  $Q_j$ .

So, this is easy because the  $Q_j$  tilde as you make them bigger and bigger, they become  $Q_j$ . So, the volume of  $Q_j$  tildes will converge to the volume of  $Q_j$  and this we can do. So, we have seen this several times in the previous arguments. So, notice that  $Q_j$  are almost disjoint, so  $Q_j$  tilde being strictly contained in inside  $Q_j$  are disjoint. So, that is that is one thing, so if you look at this as, so let us say this is  $Q_j$  and this is  $Q_j$  plus 1 tilde.

So, these two are disjoint and they are those joint compact sets, because they are bounded closed and they are disjoint compact sets. So, they have to be at a distance, so hence to let me write this statement,  $Q_j$  tilde are disjoint compact sets. So, if I take any such any two such sets, the distance between so, let us say  $Q_j$  tilde and  $Q_k$  tilde will have to be greater than 0, so, well if you have not seen this, this is an easy exercise.

So, this is true in any metric space, so let us say  $X$  is a metric space and if I take two disjoint compact sets, let us take  $A, B$  compact sets in  $X$  and  $A \cap B$  is empty. So, they are disjoint, then the distance between them is positive distance between  $A$  and  $B$  has to be strictly positive. So, remember this is the infimum of this is equally to the infimum of the distance between  $x$  and  $y$  where you take  $x$  and  $A$  and  $y$  and  $B$ .

So, that is a strictly positive quantity. So, so going back to our proof, we have  $Q_j$  tildes which are disjoint, so they are disjoint compact sets. So because of that the distance will have to be positive between any two of them. So, that tells me that, if I take  $n$  of them, so let us take  $m$  star of  $m$  star of  $Q_1$  tilde union  $Q_2$  tilde, well this would be  $m$  star of  $Q_1$  tilde plus  $m$  star of  $Q_2$  tilde.

Because so this was property, property four, of the of  $m$  star, if the distance between two sets  $E_1$  and the  $E_2$  is positive, then the  $m$  star of  $E_1 \cup E_2$  is the sum of the outer measure of  $E_1$  and outer measure of  $E_2$ . So, we know this property already. So, we applied this and I can continue, so I can look at  $m$  star of  $Q_1$  tilde union  $Q_2$  tilde union  $Q_3$  tilde, this would be  $m$  star of  $Q_1$  tilde

union  $Q_2$  plus  $m$  star of  $Q_2$ ,  $Q_3$ , because this set and this set are at a distance they both are compact sets disjoint.

So, they are the disjoint and this will add up again because of the same argument. So, I have  $Q_1$  plus  $m$  star  $Q_2$  plus  $m$  star  $Q_2$  etc. So, I can do this for and finitely many. So, continue if you continue, we get  $m$  star of union to  $Q_j$   $j$  equal to 1 to capital  $N$  let us say, this is summation  $j$  equal to 1 to  $n$  star of  $Q_j$ , because they are all compact sets disjoint, so they are at a distance and you can apply the property four again and again.

Well, we know this is  $j$  equal to 1 to capital  $N$ ,  $m$  mod  $Q_j$ , because  $Q_j$  has a cube so its outer measure is the whole  $N$  which we know is greater than or equal to  $j$  equal to 1 to  $n$  mod  $Q_j$  minus epsilon. So, let us let us go back, sorry epsilon by 2 to the  $J$ . So, we know this because we have chosen  $Q_j$ ,  $Q_j$  such that this is true  $Q_j$  such that this is true. So, remember the inequality is this way.

So, this is what we have, which of course, we can since you have epsilon by 2 to the  $J$ 's we can replace it with epsilon.

(Refer Slide Time: 18:46)

The whiteboard shows the following mathematical steps:

$$m_* (Q_1 \cup Q_2) = m_* (Q_1 \cup Q_2) + m_* (Q_3) \quad | \quad d(Q_1, Q_2) > 0$$

$$= m_* (Q_1) + m_* (Q_2) + m_* (Q_3)$$

Continuing, we get

$$m_* \left( \bigcup_{j=1}^N \tilde{Q}_j \right) = \sum_{j=1}^N m_* (\tilde{Q}_j) = \sum_{j=1}^N |\tilde{Q}_j|$$

$$\geq \sum_{j=1}^N \left( |Q_j| - \frac{\epsilon}{2^j} \right)$$

By monotonicity

$$m_* (E) \geq m_* \left( \bigcup_{j=1}^N \tilde{Q}_j \right) \geq \sum_{j=1}^N \left( |Q_j| - \frac{\epsilon}{2^j} \right)$$

$$\geq \sum_{j=1}^N |Q_j| - \epsilon$$

So, by monotonicity, we have  $m^*$  of  $E$  is greater than or equal to  $m^*$  of  $\bigcup_{j=1}^n Q_j$  because  $Q_j$  is simply smaller cubes, so  $Q_j$  tildes are the smaller cubes and union of  $Q_j$ 's is what makes up  $E$  and  $Q_j$  tildes are contained in  $E$ .

So, this union is contained in  $E$ , so this set is a subset of  $E$ , so by monotonicity we have that this by whatever we have just proved is greater than or equal to summation  $j$  equal to 1 to  $n$  mod  $Q_j$  minus epsilon by 2 to the  $J$  which of course, is greater than or equal to summation  $j$  equal to 1 to  $n$  mod  $Q_j$  minus epsilon, because epsilon by 2 to the  $J$ 's if you add you will get at most epsilon.

So, I am subtracting a bigger quantity and so, the inequality goes in this direction. So, what do we have?

(Refer Slide Time: 19:58)

$\forall N$  we have  $\sum_{j=1}^N |Q_j| - \epsilon \leq m_*(E)$  for  $N \rightarrow \infty$   
 $\epsilon \rightarrow 0$   
 we get  $\sum_{j=1}^{\infty} |Q_j| \leq m_*(E) // \Rightarrow m_*(E) = \sum_{j=1}^{\infty} |Q_j|$   
 ( $\epsilon$ -approximation of  $m_*(E)$ )  
Dy+

$E \subseteq \mathbb{R}^n$  is said to be (Lebesgue) measurable if  $\forall \epsilon > 0$   
 $\exists$  an open set  $O$  such that  $E \subseteq O$  and  $m_*(O \setminus E) < \epsilon$   
 (not same as property IV)  
Dy+

So, let us rewrite it, so what we have is for every capital N, we have summation j equal to 1 to capital n mod Qj minus epsilon is less than or equal to m star of E but this is true for every n and the right hand side has nothing to do with N. So, you can let n go to and go to infinity and epsilon go to 0.

So, let n go to infinity and epsilon goes to 0 we get we get summation j equal to 1 to infinity mod Qj is less than or equal to m star of E. So, that is the other inequality. So, let us go back to the starting of the proof, we wanted to show two inequalities, this one was trivial, this is what we

were trying to prove and what we have just established is that summation mod  $Q_j$  equals 1 to infinity  $Q_j$  is this.

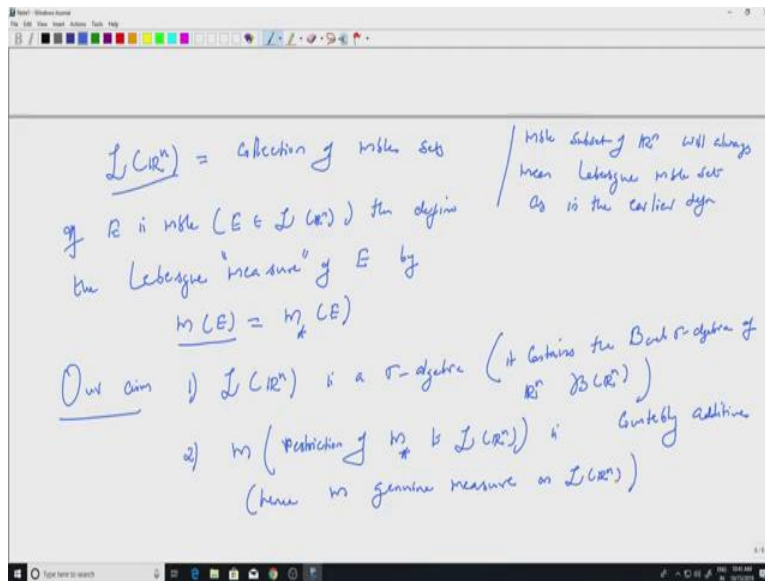

So, all these will imply that  $m$  start of  $E$  is actually equal to summation  $j$  equals 1 to infinity mod  $Q_j$ . So, we have countable additivity in a very restricted sense in the sense that if  $E$  is a set which is a countable almost disjoint union of cubes, we have additivity. So, we have five properties, so five properties of  $m^*$  is what we have, so, now let us define.

So, definition now we are ready to define the nice collection of sets on which  $m^*$  is going to be a countably additive measure define. So, you take a set which is in  $R^n$ , is said to be is said to be measurable, so we will give it a name. So, this is called Lebesgue measurable, so we will not keep saying Lebesgue measurable, we will simply say measurable by measurable, we mean Lebesgue measurable, if we are talking about sets of subsets of  $R^n$  Lebesgue measurable if for every epsilon positive.

So, this statement is important for every epsilon positive, there exist an open set, open set  $O$ , such that first of all  $E$  is contained in  $O$  and the measure of  $O$ , the outer measure of  $O$  minus  $E$  is less than epsilon. So, we are saying  $E$  can be covered by an open set  $O$ , at a size less than epsilon, so, this is important and this you should convince yourself that this is not same as the outer regularity not same as property four.

So, that is different, so there is there is a this is a slightly stronger condition than the outer regularity we had, outer regularity was true for all sets remember that all subsets of  $R^n$  had the outer regularity property, but both condition that  $m^*$  of  $O$  minus  $E$  is less than epsilon will be true only for certain sets. So, as epsilon changes the set  $O$  will change. So, the set all depends on epsilon. So, epsilon is something else epsilon becomes smaller and smaller, the set  $O$  will also have to be smaller and smaller and very close to  $E$ . So, will denote the collection of measurable sets by script  $L$  of  $R^n$ .

(Refer Slide Time: 24:13)

So we let us give it a notation. So, script  $\mathcal{L}$  of  $\mathbb{R}^n$  this is the collection of measurable set, so I will keep writing MBLE or measurable, measurable will always mean Lebesgue measurable sets.

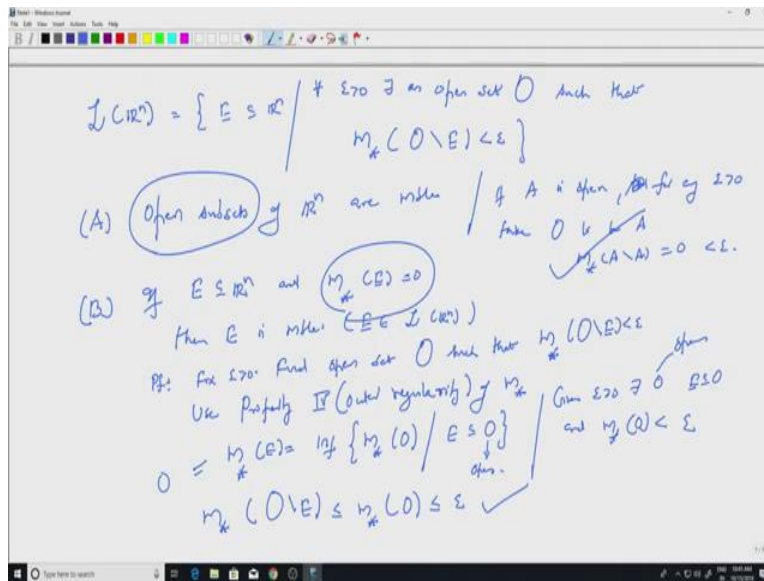

So, measurable subset of  $\mathbb{R}^n$  will always mean Lebesgue measurable set. So, as the earlier definition, So, this is the collection of measurable sets. So, if  $E$  is measurable, that means,  $E$  is a member  $\mathcal{L}$  of  $\mathbb{R}^n$  then define the Lebesgue measure of  $E$  by  $m$  of  $E$ . So,  $m$  will denote the Lebesgue measure of  $E$  to be equal to  $m_*$  of  $E$ .

So, remember  $m_*$  of  $E$  is defined for all subsets. When we say Lebesgue measure of some set, that set will have to be an element in the  $\mathcal{L}$  of  $\mathbb{R}^n$  in the collection  $\mathcal{L}$  of  $\mathbb{R}^n$ . So, our aim now we have two steps to aim. So, we have defined  $\mathcal{L}$  of  $\mathbb{R}^n$  and we have defined Lebesgue measure. So, when we say Lebesgue measure, so measure means it is a countably additive measure so, we have to show that.

So, one is to show that the collection of Lebesgue measurable sets is a sigma algebra and it contains the Borel sigma algebra of  $\mathbb{R}^n$ , remember it was denoted by script  $\mathcal{B}$  of  $\mathbb{R}^n$ , this is the smallest sigma algebra generated by open subsets of  $\mathbb{R}^n$  to  $m$ . So, what is the  $m$ ?  $m$  is simply the restriction of  $m_*$ .

So, this is the restriction of  $m^*$  to the Lebesgue sets or Lebesgue measurable set is that accountability additive measure is so  $E$  is countably additive that will do, so  $E$  is countably additive. So, that it is a genuine measure on, so hence  $m$  will be a genuine measure on  $L$  of  $\mathbb{R}^n$ . So, these are the aims.

(Refer Slide Time: 27:49)

So we will start with the, we will start with the first, first one. So look at  $L$  of  $\mathbb{R}^n$ , so remember what is this?

This is the collection of all those subsets of  $E$  which has a certain property, what is that property? For every  $\epsilon$  positive there is exists an open set, open set  $O$ . So,  $O$  depends on  $\epsilon$  remember that such that, the outer measure of  $O$  minus  $E$  is less than  $\epsilon$ , this is the property, this collection. Well what do we know? We know that, so from the definition some of the things are very trivial.

One is open sets are measurable, open subsets of  $\mathbb{R}^n$  are measurable. Well, why is that? If I take an open set  $O$ , if  $A$  is open say instead of  $O$  is open take  $O$  to be  $A$  for any  $\epsilon$  positive take  $O$  to be  $A$  itself, so you will have  $m^*(A \setminus A)$  is empty set to  $0$  and that is less than  $\epsilon$ . So, this is a trivial, trivial statement, so all the open sets are already measurable so, that is a big collection to start with.

Second if  $E$  is a subset of  $\mathbb{R}^n$  and  $m^*$  of  $E$  is 0, so size of the set is 0, then  $E$  is measurable, then  $E$  is measurable that means  $E$  is an element of  $\mathcal{L}$  of  $\mathbb{R}^n$ . Well, why is that? So, let us fix  $\epsilon$ , so prove fix  $\epsilon$  positive, I want to find an open set such that  $m^*$  of  $O \setminus E$  is less than  $\epsilon$ , find open set  $O$  such that  $m^*$  of  $O \setminus E$  is less than  $\epsilon$ .

So, use property four, so this was outer regularity of  $m^*$ . So what does it say? It tells me that  $m^*$  of  $E$  equal to infimum of, infimum of  $m^*$  of  $O$  where  $E$  is contained in  $O$ , but the left hand side is 0, so given  $\epsilon$ , so, given  $\epsilon$  positive, there exists  $O$  such that  $E$  is contained in  $O$  and  $m^*$  of  $O \setminus E$  is less than  $\epsilon$ , because it has become 0.

So, it has to be less than  $\epsilon$  for some open set  $O$ , this is open. Now,  $m^*$  of if you take that particular open set,  $m^*$  of  $O \setminus E$  I know is less than or equal to  $m^*$  of  $O$  by monotonicity and it will be less than or equal to  $\epsilon$ . So, that is  $O$  so, any set which has size 0 is measurable, open sets are measurable. So, we will stop with this right now, what we have what they have done is to restrict the outer measure to a class of sets called the Lebesgue measurable sets.

This class of sets we have to prove that it is a sigma algebra and the outer measure restricted to this is countably additive measure. So, first we are trying to prove that the Lebesgue sets form a sigma algebra, so we get a rich class of sets, there open sets are there, we have just proved that sets with size 0 are also there. So, next step will be to prove that it is a sigma algebra.
