Lecture 16

Lebesgue sigma algebra

So, we will continue looking at Lebesgue sets. So just recall that Lebesgue sets are, Lebesgue sets or Measureable set or Lebesgue Measureable sets these three terms will mean the same thing. The collection of Lebesgue sets we want to prove is a sigma algebra. So right now have all the open sets to be Lebesgue sets have sets whose outer measure is 0 also to be Lebesgue sets. We still have to prove that the collection of Lebesgue sets or the Measureable sets is closed under countable unions, compliments and well the empty set and the whole space that is the trivial condition that they are also there. So, that is our aim now.

(Refer Slide Time: 01:19)

So let us start. So, two things we have proved, so let us recall \mathcal{L} of \mathbb{R}^n . So, \mathcal{L} of \mathbb{R}^n is the collection of sets E contained in \mathbb{R}^n such that for every epsilon positive there exist an open set, open set O such that the measure of O minus E is less than epsilon. This is the condition we have.

So, what we have just shown is that open sets belong to \mathcal{L} of \mathbb{R}^n that is trivial, B we have shown that if $m^*(E) = 0$, then E is a Measureable set. So, let us go to the non-trivial properties, countable union of Measureable sets is measurable. So, that is the,

that one of the properties of the sigma algebra that the collections of the sets should be closed under countable union.

So, what did we just say that is, so let us complete the sentence that is, if E_j they are the sets in L of \mathbb{R}^n that is $E_j \in \mathcal{L}$ measurable j equal to 1, 2, 3, etcetera. Then the union of E_j , so let us call that E , E equal to $\bigcup_{j=1}^{\infty} E_j$. That is also a Measurable set, so it belongs to L of \mathbb{R}^n . So let us proof this, so this is not very difficult it follows from whatever sub additivity property we have for the outer measure.

So, each E_j is measurable, so let us fix an epsilon first. So, we start with that, fix an epsilon, fix epsilon positive, so remember to show that E is measurable what we do fix epsilon positive and then construct an open set so that this is true. So, let us start with E_j I have fixed an epsilon, so we have, we have open set, open set let us call that O_j because that is one works for E_j , such that first of all E_j should be contained in O_j .

So, that is condition which you should always remember the set should be contained in the open set and the outer measure of the difference. So you approximate the set nicely by open set. That is what measurability, qualitatively means, that is nicely approximated by open sets from above. So, this would be less than or equal to epsilon by 2^{-j} . So, you have seen this argument before epsilon by 2^{-j} . So instead of taking epsilon, I take epsilon by 2^{-j} as a positive number and I have an open set for this.

So, now it should be obvious to you what to do because I have O_j for each E_j . So, for E I should take union of E_j , so the corresponding open set should be union of O_j . So, take O to be union of O_j j equal to 1 to ∞ this is of course open because each E_j each O_j is open and I am taking the union of open sets, union of open sets is open.

So, that is union of open sets is open. So because of that so now we want to approximate the set E by O so take, so look at O minus E and I want to look at the outer measure of those and say that it is small. Well what is this, this union O_j j equal to ∞ minus union E_j j equal to 1 to ∞ . So, this I will leave it to you to check that this is actually contained in it is not equal to it is contained in union j equal to 1 to ∞ O_j minus E_j . Check this, this is a trivial set theoretic exercise.

(Refer Slide Time: 06:11)

$$m_*(O \setminus E) \leq m_* \left(\bigcup_{j=1}^{\infty} (O_j \setminus E_j) \right) \quad (\text{monotonicity})$$

$$\leq \sum_{j=1}^{\infty} m_* (O_j \setminus E_j) \quad (\text{Sub-additivity})$$

$$\leq \sum_{j=1}^{\infty} \frac{\epsilon}{2^j} = \epsilon$$

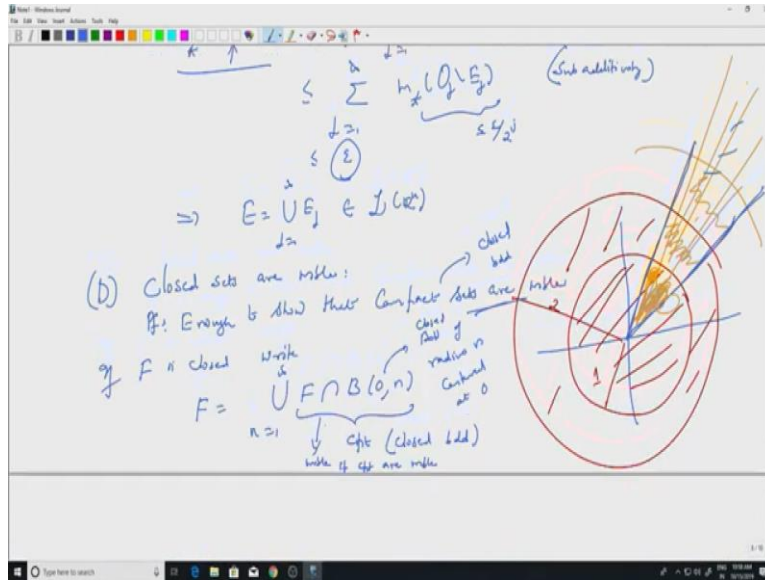

$$\Rightarrow E = \bigcup_{j=1}^{\infty} E_j \in \mathcal{L}(\mathbb{R}^n)$$

(b) Closed sets are mble:
 Pf: Enough to show their Compact

$$\mathcal{L}(\mathbb{R}^n) = \left\{ E \subseteq \mathbb{R}^n \mid \exists \epsilon > 0 \text{ and an open set } O \ni m_*(O \setminus E) < \epsilon \right\}$$

(A) open sets $\in \mathcal{L}(\mathbb{R}^n)$
 (B) $m_*(\emptyset) = 0$ then $\emptyset \in \mathcal{L}(\mathbb{R}^n)$
 (C) Countable union of mble sets is mble, That is, if $E_j \in \mathcal{L}(\mathbb{R}^n) \forall j=1,2,\dots$
 Then $E = \bigcup_{j=1}^{\infty} E_j \in \mathcal{L}(\mathbb{R}^n)$

Pf: $\epsilon > 0$
 For $E_j \in \mathcal{L}(\mathbb{R}^n)$, we have open set O_j , $E_j \subseteq O_j$ and $m_*(O_j \setminus E_j) < \frac{\epsilon}{2^j}$
 Take $O = \bigcup_{j=1}^{\infty} O_j \rightarrow$ open (union of open sets is open)
 $O \setminus E = \bigcup_{j=1}^{\infty} (O_j \setminus \bigcup_{k=1}^{\infty} E_k) \subseteq \bigcup_{j=1}^{\infty} (O_j \setminus E_j)$ (check)
 $m_*(O \setminus E) \leq \sum_{j=1}^{\infty} m_*(O_j \setminus E_j) < \sum_{j=1}^{\infty} \frac{\epsilon}{2^j} = \epsilon$ (monotonicity)

Because of this, so hence I can apply subadditivity, monotonicity. So, $m^*(O \setminus E) \leq m^*(\bigcup_{j=1}^{\infty} (O_j \setminus E_j))$ which is less than or equal to $\sum_{j=1}^{\infty} m^*(O_j \setminus E_j)$ which is less than or equal to $\sum_{j=1}^{\infty} \epsilon/2^j$. So, this is just monotonicity and this will be less than or equal to ϵ . By sub additivity and of course less than or equal to ϵ because each of them is less than or equal to $\epsilon/2^j$ and I am adding them, so I will get ϵ and that is all I need.

So, this implies, so for every ϵ I have found an open set O such that this is less than or equal to ϵ . So, this implies that the set E this is the union of E_j j equal to 1 to infinity is measurable. That is precisely what we wanted to prove. So, we have proved C. So, this is one of the properties for \mathcal{L} of \mathbb{R}^n to become a sigma algebra. We are still two steps away from proving that it is a sigma algebra. So, let us do that, so that is the next one let us call that D close sets are measurable, close sets are measurable.

So go back the first one is that open sets are measurable but that was trivial, now we are saying close sets are measurable. So, that is like taking the compliment of course we do not know if we take the arbitrary set in \mathcal{L} of \mathbb{R}^n and take the compliment we still land in \mathcal{L} of \mathbb{R}^n , we do not know yet. But this is the first step close sets are measurable. So let us, let us proof this, so first thing to notice is that enough to, enough to show that compact sets are measurable, compact sets are measurable. So why is that?

So let me draw some picture for you, the close sets, so compact sets are closed and bounded, it is closed and bounded. So close sets need not be bounded it can be an unbounded set. So let us say we have an unbounded close set so something like this, so let us take this sector so this including the boundary lines. So that it will be a close set everything whatever is inside, what you do is you take, you take a ball of radius 1 and then you take a ball of radius 2 and so on this is radius 2. So, this portion is this the intersection of ball of radius 1 with the close set that is compact.

Similarly this portion that is compact and so on. So, what we can do is if you intersect with balls of radius n and take the union I am going to get well, so when you intersect you will, when you intersect you get only this portion. Whatever is inside, so this would be compact and then you will get this portion which is compact then you will this portion which is compact and so on.

So, you can write the close set as a union of countable union of compact sets. So, that is the reason, so let us write that, so if F is closed you can write F to be union of F intersected with ball of radius n centered at 0 n equal to 1 to infinity. So, this is ball closed ball of radius n centered at, centered at 0 and each of them is compact this is compact because it is closed and bounded, closed and bounded and it is a countable union.

So, if compact sets are measurable then these are measurable if compact sets are measurable and the earlier property we have proved is that countable union of Measureable sets is measurable. The property C which we countable union of Measureable sets is measurable. So, it is enough to show that each of these intersections is measurable then the, because it the countable union we are done. So that is why it is enough to show that compact sets are measurable.

(Refer Slide Time: 11:49)

m_* if Q are finite
 Let $F \subseteq \mathbb{R}^n$ be a compact set (closed and $\exists Q \ni F \subseteq Q$)
 $m_*(F) < \infty$
 $m_*(F) = \inf \{ m_*(Q) \mid F \subseteq Q \text{ open} \}$
 Outer regularity \leftarrow Property IV of m_*
 $m_*(Q) = |Q| < \infty$

$m_*(F) < \infty$
 $m_*(F) = \inf \{ m_*(Q) \mid F \subseteq Q \text{ open} \}$
 Outer regularity \leftarrow Property IV of m_*
 Given $\epsilon > 0 \exists$ open set $O \supseteq F \subseteq O$ and
 $m_*(O) \leq m_*(F) + \epsilon$
 $O \setminus F = O \cap F^c$ open $= \bigcup Q_j$
 Let $K = \bigcup_{j=1}^N Q_j$ - finite disjoint from F (F - Q_j disjoint)
 $d(K, F) > 0$
 $K \cup F \subseteq O$
 Q_j - almost disjoint closed cubes
 Q_j - open

So we will do that, so let f contained in \mathbb{R}^n be a compact set, be a compact set. We want to show that F is Measurable, since it is a compact set it is closed and bounded. So, it will be closed and bounded, so there exist some big cube Q such that F is contained in Q , So, because of that M^* of F the outer measure of F will be, will be finite.

Because the compact set will be something like this close and bounded and you have a big cube surrounding it because it is close and bounded you can put it inside a big cube and M^* of Q is

the volume of Q . So, this is finite, it is a product of the side length, so with that is finite and so compact sets will have outer measure finite.

So, now use property 4 of M^* . We know that M^* of F is equal to infimum of M^* of O with f contained in O and O open. That is the outer regularity so property 4 is the outer regularity which is true of all subsets of \mathbb{R}^n . So, we have this property we use this so now may be some picture is needed, so let us let us take this picture so I have F and I have so let us draw this picture again, so I have I have F which is a closed and bounded set this is my F and I am putting it so there is an open set around it so let us draw an open set around it.

I am drawing a bigger open set just to, so that the picture is clear, so it will be a much smaller open set. So, given ϵ I can so given ϵ positive there exist open set O such that F is contained in O and M^* of O is less than or equal to M^* of F plus ϵ , that is the property of infima. You look at M^* of F plus ϵ there would be an element from that set which is less than or equal to that, that is M^* of O .

Now you look at O minus F . So, what is O minus F ? So that is this portion so this is O minus F . this will be open why is that? Well O minus F by definition is O intersected with F compliment. So, you are looking at O which is an open set and F compliment which is an open set and you are in the set T . So, this is open, because it is open you can write this as, so this is one of the properties we proved when we started with rectangles you can write this as union of Q_j , j equal to 1 to infinity Q_j close cubes almost disjoint close cubes. Almost disjoint closed cubes.

This was one of the properties we proved. So let me, let me try to show this in the picture so we can write the remaining of F inside O as, it need not be of same size, some may be bigger some may be smaller and things like that. So, this part is written as disjoint union of almost disjoint union of closed cubes. So, now you take finitely many of them, so let K be equal to union j equal to 1 to n Q_j . So, I am taking only finitely many, so you take may be this one Q_1 may be this one, may be this one and this one and so on.

So you take finitely many. Then this is also compact because finite union of this is compact, disjoint from F remember both are compact sets. So, F compact K compact disjoint because the Q_j s are inside the compliment of F , it is inside O minus F , you are writing O minus F as union of

Qs and you are taking Qs. So they are disjoint, so I have two compact sets which are disjoint, so the distance between them will be greater than 0, because they are 2 disjoint compact sets.

So, this was the earlier exercise I gave if you have two compact sets, which are disjoint then their distance is positive and also $K \cup F$ is contained in O . So let us look at the picture again.

So, I am taking the compliment of F , so O minus F that is this portion that is written as union of Qs, I take finitely many Qs and F . So, F is this. So that will be inside O , I am going outside the open set I started with.

(Refer Slide Time: 17:54)

Let $K = \bigcup_{j=1}^{\infty} Q_j$ disjoint from F (F - ckt, K - ckt)
 $d(K, F) > 0$ almost disjoint
 $K \cup F \subseteq O$

Applying monotonicity $m^*(O) \geq m^*(K \cup F)$
 $= m^*(K) + m^*(F)$
 $= m^*(F) + \sum_{j=1}^{\infty} m^*(Q_j)$
 $E = \bigcup_{j=1}^{\infty} Q_j$ almost disjoint
 $m^*(E) = \sum_{j=1}^{\infty} I(Q_j)$

$$= m_*(K) + m_*(F) \quad d(K, F) > 0$$

$$= m_*(F) + \sum_{j=1}^N m_*(Q_j)$$

$$E = \bigcup_{j=1}^N Q_j \text{ almost disjoint}$$

$$m_*(E) = \sum_{j=1}^N |Q_j|$$

Hence $\sum_{j=1}^N |Q_j| \leq m_*(O) - m_*(F) \leq \epsilon \quad \forall N.$

$$\Rightarrow \sum_{j=1}^{\infty} |Q_j| \leq \epsilon$$

$$m_*(O \setminus F) = m_*(\bigcup_{j=1}^{\infty} Q_j) \leq \sum_{j=1}^{\infty} m_*(Q_j) \leq \epsilon \Rightarrow F \text{ is m.k.}$$

$$\Rightarrow E = \bigcup_{j=1}^{\infty} E_j \in \mathcal{L}(\mathbb{R}^n)$$

(d) Closed sets are m.k.:
 Pf: Enough to show their compact sets are m.k.

If F is closed, write $F = \bigcup_{n=1}^{\infty} F \cap B(0, n)$
 Each $F \cap B(0, n)$ is compact (closed bdd) m.k. if cts are m.k.

Let $F \subseteq \mathbb{R}^n$ be a compact set (closed bdd, $\exists Q \ni F \subseteq Q$)
 $m_*(F) < \infty$.
 $m_*(F) = \lim_{n \rightarrow \infty} m_*(F \cap B(0, n)) / F \subseteq O \text{-ctn}$
 $F \subseteq O$ and

So, because of so apply monotonicity, monotonicity so you will get M star of O to be greater than or equal to M star of K union F , because K union F is a subset of this which is equal to M star of K plus M star of F , why is that? Because the distance between K and F is positive and we know that M star add sub when you have disjoint sets at a distance at a positive distance, which is equal to M star of F . So, that stays as it is plus well what is K ? K is the union K is the union of Q_j s where are almost disjoint, almost disjoint.

So, that was the property we proved earlier if you have almost disjoint union of sets then M star will add up. So, this is simply summation, so M star of K would be summation J equal to 1 2 capital N , M star of Q_j . This was one of the property remember that if you write E as union E_j

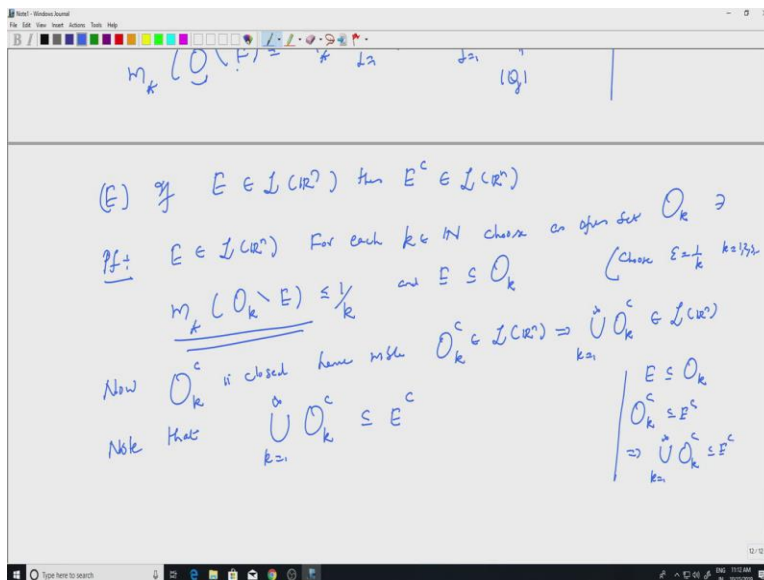

almost disjoint Q_j almost disjoint, then $m^*(E)$ was equal to $\sum_{j=1}^{\infty} m(Q_j)$. Countability but a very restricted countability. So this is true, hence so now we apply whatever we know as a, so this remember is simply the volume of Q_j . So, if you look at $\sum_{j=1}^N m(Q_j)$ this would be less than or equal to $m^*(O) - m^*(F)$. Remember everything is finite $m^*(F)$ is finite, $m^*(O)$ is also finite.

So this is less than or equal to ϵ . Because we started with the set O so that so that this is 2. So because of that $m^*(O)$ so remember this implies that $m^*(O)$ is also finite. Because $m^*(F)$ is finite, F is a compact set and is less than or equal to ϵ . But this is true for every ϵ for every capital N . So, I can let N go to infinity, so this will immediately imply $\sum_{j=1}^{\infty} m(Q_j)$ is less than or equal to ϵ .

Well what does that say what is Q_j s? So, remember the open set $O - F$, as $\cup_{j=1}^{\infty} Q_j$. This was this was the open set and this was almost disjoint unit, almost disjoint unit. So, if you look at the outer measure of the open set $O - F$ this is nothing but well $m^*(\cup_{j=1}^{\infty} Q_j)$. But remember this is a countable almost disjoint union of cube, so we know that it by well you can apply sub additivity. Here if you want, $\sum_{j=1}^{\infty} m(Q_j)$, and I know this is simply $\sum_{j=1}^{\infty} m(Q_j)$ but we know that this is less than equal to ϵ . So, apply this less than or equal to ϵ .

So that is all. So we, this implies that F is Measureable, F is Measureable, why? Because we have found an open set O such that $O - F$ has size less than or equal to ϵ . Whatever ϵ you start with, so that tells me that the compact set E is measurable. So what that gives me is because any closed set is an countable union of compact sets and compact sets are measurable closed sets are measurable.

(Refer Slide Time: 22:25)

Let us go to the next property we are still far away from proving that it is a sigma algebra. So the next property will tell me it is a sigma algebra. So if E belongs to L of Rn then E complement belongs to L of R, so we already proved that countable union of measurable sets is measurable. Now we are proving that it is closed under complementation, so that will tell me that the collection of measurable sets form a sigma algebra.

So, let us prove this, so if I take E in L of Rn what do I have for each, so let me write down the statement and then explain, for each k in natural numbers choose an open set we will call that Ok, such that the size of Ok minus E this is less than or equal to 1 by k and of course the set E should be contained in Ok.

This is true, because, I can do this for every epsilon, so choose epsilon to be 1 by k. So, this is simply choosing epsilon to be 1 by k, where k is 1, 2, 3, etcetera. So, for each epsilon I have an open set. So, for epsilon equal to 1 by 2, 1 by 3, 1 by 4 etcetera we get open sets O1, O2, O3, O4, etcetera with this property. Now Ok complement if I look at the complement of Ok this is closed this is closed. Hence, measurable we just proved that closed sets are measurable.

So Ok complement is a element of L of Rn. So this would imply union of Ok complement k equal to 1 infinity is also in L of Rn. We proved that countable union of measurable sets is a measurable set. So I am taking Ok compliments and taking the union. So that is also a

measurable. So note that note that union k equal to 1 to infinity O_k compliment is contained in E compliment. Well why is that? Because each of them is contained in E compliment, so the union is also contained in E compliment. Remember, so this is simply because we looked at O_k which is like this, so this tells me that O_k set compliment is contained in E compliment.

So, this would of course imply the union is also contained in E compliment. So, we are in good shape. So we continue, now some set theoretic inclusions are needed. So this is a slightly it will look messy but it is actually pretty trivial.

(Refer Slide Time: 26:07)

Handwritten mathematical derivation on a whiteboard:

Here $E^c \setminus \left(\bigcup_{k=1}^{\infty} O_k^c \right) \in \mathcal{L}(\mathbb{R}^n)$

$D \subseteq A$
 $(A \setminus D) \cup B = A$
 $\left. \begin{array}{l} E^c \setminus \left(\bigcup_{k=1}^{\infty} O_k^c \right) \in \mathcal{L}(\mathbb{R}^n) \\ \bigcup_{k=1}^{\infty} O_k^c \in \mathcal{L}(\mathbb{R}^n) \end{array} \right\} \text{but } O_k^c \text{ - closed } \in \mathcal{L}(\mathbb{R}^n)$

Take union we get $E^c \in \mathcal{L}(\mathbb{R}^n)$

Handwritten mathematical derivation on a whiteboard:

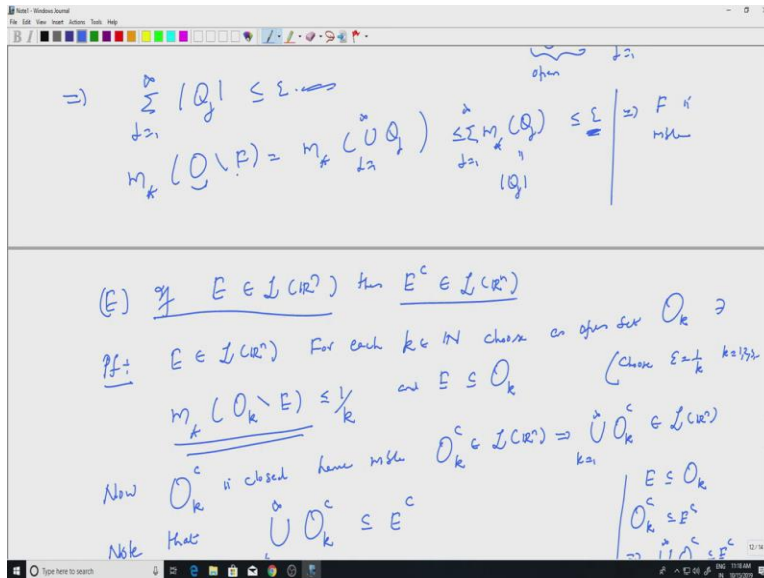

Now, $E^c \setminus \left(\bigcup_{k=1}^{\infty} O_k^c \right) \subseteq O_j^c \setminus E$

Apply monotonicity of \cap to get $\mathcal{M}_* (E^c \setminus \left(\bigcup_{k=1}^{\infty} O_k^c \right)) \subseteq \mathcal{M}_* (O_j^c \setminus E)$

$\mathcal{M}_* (E^c \setminus \left(\bigcup_{k=1}^{\infty} O_k^c \right)) \subseteq \mathcal{M}_* (O_j^c \setminus E) \subseteq \mathcal{M}_* (O_j^c) \subseteq \mathcal{M}_* (E^c) = \mathcal{M}_* (E)$

$\mathcal{M}_* (E^c \setminus \left(\bigcup_{k=1}^{\infty} O_k^c \right)) \subseteq \mathcal{M}_* (O_j^c \setminus E) \subseteq \mathcal{M}_* (O_j^c) \subseteq \mathcal{M}_* (E^c) = \mathcal{M}_* (E)$

$\mathcal{M}_* (E^c \setminus \left(\bigcup_{k=1}^{\infty} O_k^c \right)) \subseteq \mathcal{M}_* (O_j^c \setminus E) \subseteq \mathcal{M}_* (O_j^c) \subseteq \mathcal{M}_* (E^c) = \mathcal{M}_* (E)$

So let me write down that the first. So E complement, so now what we do is check this E complement minus union k equal to 1 to infinity O_k complement, so I will take this, this is contained in O_j minus E for every j . So, this looks a bit messy but let us see why?

So let us prove this so what is the LHS? So, LHS is E complement intersected with the complement of whatever is there A minus B is the intersection of A with B complement. So, LHS is equal to E complement intersected with the complement of this. So let, I will write one more step. So, that is this clear, k equal to 1 to infinity O_k complement whole complement. So, it looks messy as I said but it is exactly pretty trivial.

Which is E complement intersected with so if I take the complement of the union I will get the intersection of the complement. So, that is intersection of k equal to 1 to infinity O_k . Which is of course contained in E complement intersect any of them O_j for every j . But E complement intersection O_j is simply O_j minus E . So, that is all is the here. So, proof though even though it looks messy the proof is rather set theoretic inclusions and its sort of straight forward.

So, now apply M^* applies monotonicity of M^* to get M^* of E complement minus union k equal to 1 to infinity O_k complement is less than or equal to M^* of O_j minus E for every j . So, the right hand side has j but the left hand side have is independent of j .

So I can put j , I can let j go to infinity and this will go to 0 because this thing is less than or equal to 1 by j . That is how we have chosen the sets O_k remember that it is less than equal to 1 by k . So, here O_j will be less than equal to 1 by j and like j go to infinity I will get 0. So, what does

that mean? That means this side is equal to 0, so I have a set whose outer measure is 0, so that belongs to the Lebesgue sigma algebra.

So hence, let us write it here hence $E^c = \bigcap_{k=1}^{\infty} O_k$ belongs to Lebesgue sigma algebra because it has size 0. Any set which has $M^* \text{ outer measure } 0$ is a measurable set. So, let us let me write down two things, so that the we can stop, so this would be $\bigcap_{k=1}^{\infty} O_k^c$, this I know now belongs to L of \mathbb{R}^n . I also know that $\bigcup_{k=1}^{\infty} O_k^c$ also belongs to L of \mathbb{R}^n . Why is that? Because O_k^c is closed and so belongs to L of \mathbb{R}^n and countable union of Measurable sets is measurable.

So, I have two things belonging to L of \mathbb{R}^n . So, if I have two sets belonging to L of \mathbb{R}^n their union will also belong. So, take union, take union, so union is simply, so I am subtract, so it is like, it is like $A \setminus B \cup B$, this is simply A because B contained in A . So, remember B is contained in it. So, when you take the union you will get, we get E^c and of course if this belongs to L of \mathbb{R}^n , so one of them belong to L of \mathbb{R}^n and the second set also belongs to L of \mathbb{R}^n then the union is in L of \mathbb{R}^n .

So that is all we need. So, we proved that if E belongs to L of \mathbb{R}^n measurable then E^c also belongs to L of \mathbb{R}^n . So, we can stop with this, what we have proved is that the Lebesgue sets the Lebesgue Measurable sets defined using $M^* \text{ of } O \text{ minus } E \text{ to be less than } \epsilon$ or in other words for every ϵ there is an open set O such that $M^* \text{ of } O \text{ minus } E \text{ is less than } \epsilon$.

That collection of sets E with this property called the Lebesgue sets form a sigma algebra. We proved that countable union of Measurable sets is measurable and we just proved that if E is measurable set its complement is also a measurable set. Now the outer measure restricted to the sigma algebra, we have to prove that it is countably additive. So, that will complete the construction of the Lebesgue measure. So that is what we will do in the coming lecture.
