Fine Properties of Measurable Sets

So, now we have constructed the Lebesgue Measure, we know that it is a countably additive measure. We saw some examples, we will be looking at finer properties of the measurable sets how to approximate it with nice sets like compact sets F sigma sets G delta sets and things like that. And we will also compare it with the Borel sigma algebra which we already talked about earlier. So, let me write down some things now as questions, and we will take it up later. And then we will go on to look at some finer properties of measurable sets.

(Refer Slide Time: 01:18)

So, let us recall we have \mathbb{R}^n we have the Lebesgue measure, the Lebesgue sigma algebra and we have the Lebesgue measure m . So, recall that we have, recall that the Borel sigma algebra. So, this is what we initially defined, Borel sigma algebra of \mathbb{R}^n . So, what was this? This was the smallest sigma algebra, smallest sigma algebra containing open set, sigma algebra containing open sets.

So, we had looked at it, we had looked at examples in Borel sigma algebra and so on. So, note that, note that open sets are open sets are inside Lebesgue sets, inside the Lebesgue sigma algebra, that is by definition itself it will follow. So, since this is a sigma algebra it will also follow that the Sigma algebra generated by open sets will also be here, which means the

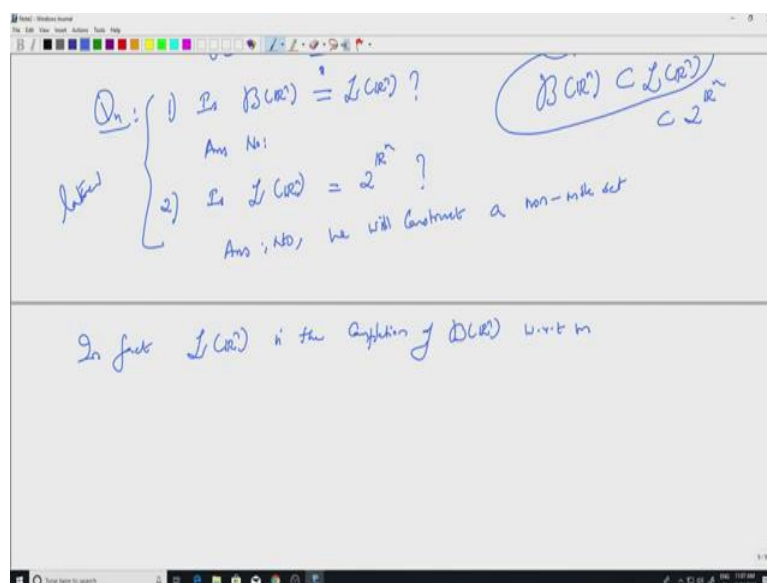

Borel sigma algebra which is generated by the open sets will be contained in the Lebesgue sigma algebra.

So, this is a rather large collection and of course, all these are subsets of \mathbb{R}^n . So, these are all contained in $2^{\mathbb{R}^n}$, $2^{\mathbb{R}^n}$ by this we mean the power set of, power set of \mathbb{R}^n we started with that. On, we defined M^* on the power set of \mathbb{R}^n , the outer measure was defined on the power set of \mathbb{R}^n and then we restricted it to L of \mathbb{R} . So, there are two questions whether these are equal there is equality at any level?

So, may be let me write it as a question 1 is B of \mathbb{R}^n , that is the Borel sigma algebra, is it equal to the Lebesgue sigma algebra? So, answer is no. We will see examples later. 2 is the Lebesgue sigma algebra equal to the power set well, here also the answer is no, the answer is no. We will construct, we will construct a non-measurable set, a non-measurable set, probably in the next few lectures we will do that and of course, this so these things will be taken up later.

So, Lebesgue sigma algebra is something which is in between the Borel sigma algebra and the power set. So, B of \mathbb{R}^n is actually strictly contained in the Lebesgue sigma algebra strictly contained in $2^{\mathbb{R}^n}$, the powers. But these two, do not differ too much the Borel sigma algebra and Lebesgue sigma do not differ too much, we will see that the Lebesgue sigma algebra is actually.

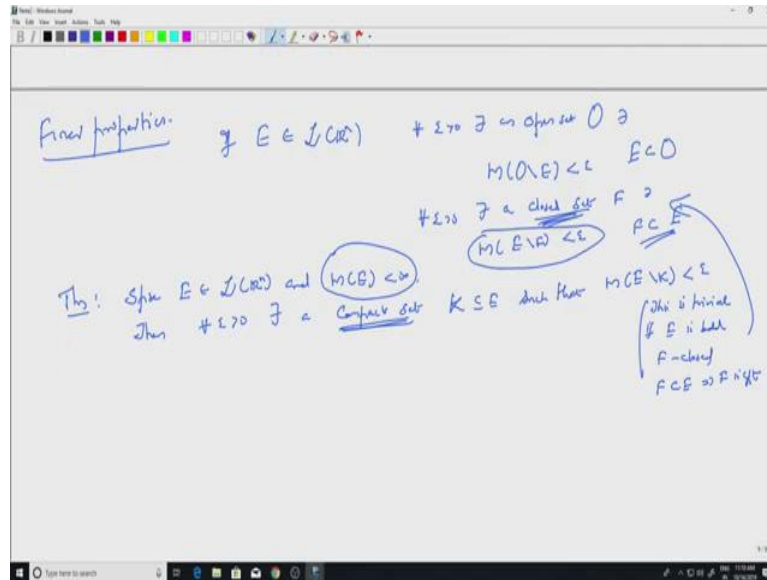

(Refer Slide Time: 04:42)

So, we in fact inside the Lebesgue sigma algebra is the completion of, is the completion of the Borel sigma algebra with respect to the Lebesgue measure. So, remember we define

completion, this is simply by adding all the sets of measures 0 subsets of measures 0. So, if you start with Borel sigma algebra and add subsets of measures 0 you will get Lebesgue sigma algebra.

(Refer Slide Time: 05:19)

So now, now, let us look at finer properties of the Lebesgue sets. So, let us say finer properties finer properties, I can write it as a theorem. So, if I, before we state the theorem, so if, I have a measurable set. Well, I already know that for every epsilon positive, there exist an open set open set O, such that measure of O minus E is less than epsilon, I will not use M star anymore because these are all measurable sets. So, I will just use m, we also know that for every epsilon positive there exists so, the open set O is such that it is bigger than E.

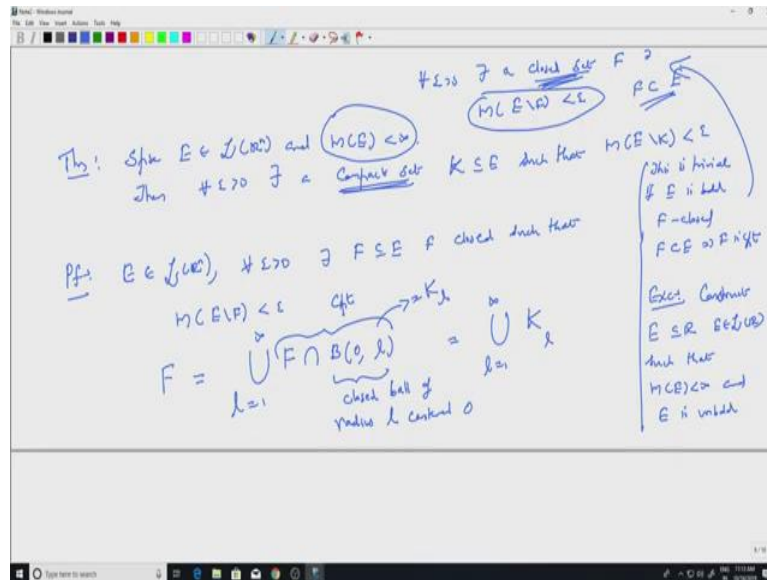

So, there exists a closed set now, this also we know F such that measure of E minus F is less than epsilon, where F is a subset of subset of E. So, you can approximate E from outside by open sets and from inside by closed sets. So, this these are equal in statements we have seen that So, I can choose any of them for measurability.

So, let me write another theorem suppose, E is a measurable set and it has finite measure then for every epsilon positive there exists a compact set k contained in E such that measure of E minus the compact set is less than epsilon. So, that is a strengthening of whatever we have here whatever you have measurability you have a closed set contained in E such that we have this inequality.

Now, we are saying we have a compact set what is the assumption assumption remember is a set which has finite measurable. For example, if E is bounded this is trivial because if it is, so

this is trivial if E is bounded because the closed set F contained in E implies F is bound F is compact. So, this will already imply that but E need not be bounded. So, that is a exercise.

(Refer Slide Time: 08:25)

So, here you can convince yourself about this. So, simple exercise construct a set E contained in the real line measurable, such that measure of E is finite and E is unbounded think of union of intervals which are under unbounded so let us prove this.

So let us go back to the statement and If I have a set of finite measure, it can be approximated from inside by compact sets that is the statement. So, because of measurability for, for epsilon positive, we already have the closed set right. So, there exists F which is contained in E F closed such that, such that the measure of E minus F is less than epsilon. So, that is simply the definition of measurability.

So, what we do is we write F as union, let us say l equals 1 to infinity, F intersected with closed ball of radius l centered at 0. So, this is the closed ball, close ball of radius l, centered at 0, centered at origin. That is a compact set. So F is closed, this is compact so when I intersect, this is going to be compact. So, let us call that K_l , so l equal to 1 to infinity I will write it as K_l . So, K_l is this this intersection this K_l . So, I am writing F as a countable union of compact sets.

(Refer Slide Time: 10:54)

Now we want to approximate E from inside. So, you look at E minus K_l , so may be one more. Let me write this a bit more clearly. So, what is K_l ? K_l is not the ball it is F intersected with the ball. So this is compact. Look at E minus K_l , remember F was a closed set contained in E I am looking at E minus K_l , K_l is contained in F because it is F intersection something I am looking at E minus K_l .

Well what happens so this K_l increased to F , K_l increased to F . So, E minus K_l will decrease to E minus F . So, this you can check this is a trivial theoretic exercise. But I know that, I know that measure of E minus F this is less than epsilon that I know given epsilon I have this F . So, measure of E minus K_l will decrease to measure of E minus F .

This is from the general theorem, general theorem, what is the general theorem if I have a triple and if I know that A_n decreases to A then μ of A_n decreases to μ of A provided, one of them as finite measure right μ of A_1 has finite measure here everything is bounded. So, all these things are finite. So, there is no problem E minus K μ of E itself is finite.

So, let us see why we can use this. So, μ of E is finite. So, all these are finite quantities and so, this theorem applies. But μ of E minus F is less than ϵ . So, this will have to be less than ϵ after some time. So, for all large l , μ of E minus K l is less than ϵ that follows from the definition of the convergence.

So, that is all we need we need a compact set we need a compact set K such that μ of E minus K is less than ϵ . So, we have proved so, that is one finer property so far I have said which has finite measure, I can approximate it from inside using compact sets so let us look at one more search result.

(Refer Slide Time: 13:59)

Thy: Spke $m(E) < \infty$. Given $\epsilon > 0$, \exists a finite union $F = \bigcup_{j=1}^n Q_j$ such that $m(E \Delta F) < \epsilon$.

Q_j - closed cubes such that $m(E \Delta F) < \epsilon$

Proof: Given $\epsilon > 0$, let $\{Q_j\}$ be the collection of closed cubes such that $E \subseteq \bigcup_{j=1}^{\infty} Q_j$ and $\sum_{j=1}^{\infty} m(Q_j) \leq m(E) + \frac{\epsilon}{2}$.

$m(E) < \infty$, $\sum_{j=1}^{\infty} m(Q_j) < \infty$. $\exists N$ large enough such that $\sum_{j=N+1}^{\infty} m(Q_j) \leq \frac{\epsilon}{2}$.

Let $F = \bigcup_{j=1}^N Q_j$. Then $m(E \Delta F) < \epsilon$.

The distance of $F \subseteq E$ is finite.

Thy: Spke $E \in \mathcal{J}(\mathbb{R}^n)$ and $m(E) < \infty$. Then $\exists \epsilon > 0$ \exists a compact set $K \subseteq E$ such that $m(E \setminus K) < \epsilon$.

Proof: $E \in \mathcal{J}(\mathbb{R}^n)$, $\exists \epsilon > 0$ $\exists F \subseteq E$ closed such that $m(E \setminus F) < \epsilon$.

$F = \bigcup_{k=1}^{\infty} (F \cap B(0, k)) = \bigcup_{k=1}^{\infty} K_k$

$K_k \subseteq F \subseteq E$

$K \uparrow F$

$K \subseteq F \subseteq E$

$E \setminus K = E \setminus \bigcup_{k=1}^{\infty} K_k = \bigcap_{k=1}^{\infty} (E \setminus K_k)$

$E \setminus K_k \subseteq E \setminus F \cup (F \setminus K_k)$

$m(E \setminus K) \leq m(E \setminus F) + m(F \setminus K)$

$m(E \setminus K) < \epsilon + \epsilon = 2\epsilon$

$\exists N$ such that $m(F \setminus K_N) < \epsilon$

Let $K = K_N$. Then K is compact and $m(E \setminus K) < 2\epsilon$.

Since ϵ is arbitrary, we can choose $\epsilon = \frac{\epsilon}{2}$ to get $m(E \setminus K) < \epsilon$.

Suppose m of E is finite then there exist a finite union, finite union we will call F to be equal to union Q_j , j equal to 1 to n , what are Q_j ? Q_j closed cubes, closed cubes such that, such that measure of $E \Delta F$. So, that is a symmetric difference that is less than epsilon. So, of course then given epsilon, so let me write this part again given epsilon positive, there exist, there exist a finite union F such that $E \Delta F$.

So, what is $E \Delta F$? $E \Delta F$ is a symmetric difference. So, this is E minus F union F minus E . So, difference between E and F is very small. So, E is sort of approximated by a finite union of closed cubes. So, that is slightly stronger than or finer than this property because we have here we have arbitrary closed sets, what we are, here what we are essentially saying that close, the compact set can be a union of close cubes.

So, let us look at the proof, proof follows from whatever we have just done well, not really. So, let Q_j be the collection of be a collection, of closed cubes, closed cubes such that...So, here in the statement you should realize that F is not contained in E . So, so we are not unlike the earlier theorem, theorem does not say does not say that F is contained in E this need not be true. So F , because E may not have an interior at all. So, F is contained in E , E is not true may not be true does not say.

So, let Q_j with a collection of closed cubes such that E is contained in union Q_j j equal 1 to infinity. So, this is one of the first arguments we had right using the property of the infimum summation j equal to 1 to infinity mod Q_j is less than or equal to measure of E plus epsilon by 2. So, given epsilon, so, given epsilon positive and Q_j be the collection of closed cubes such that this happens, this this we know that exists.

So, that follows from the... So, this is from the definition of outer measure, definition of m^* and m are same right for measurable sets. But m of E is finite, m of E is finite. So, this quantity is finite. So, this quantity also has to be finite the infinite sum of mod Q_j will have to be finite. So, there exist some capital N large enough, large enough.

So, that the tail of the series is small, that means summation j equal to N plus 1 to infinity now. So, that is the tale of the series. So, this is the tale of the series, series converges. So, the tale of the series will have to be small less than or equal to epsilon by 2, I can do this. So, I can choose a large enough m , so that this happens.

(Refer Slide Time: 18:43)

The image shows a whiteboard with handwritten mathematical derivations and a Venn diagram. The text on the whiteboard is as follows:

Take $F = \bigcup_{j=1}^{\infty} Q_j$ (finite union of closed cubes)

Claim $m(E \Delta F) \leq \epsilon$

$m(E \Delta F) = m(\underbrace{E \setminus F}_{\text{disjoint}} \cup \underbrace{F \setminus E}_{\text{disjoint}})$

$= m(E \setminus F) + m(F \setminus E)$

$\leq m(\bigcup_{j=N+1}^{\infty} Q_j) + m(\bigcup_{j=1}^N Q_j \setminus E)$

$\leq \sum_{j=N+1}^{\infty} |Q_j| + \left(\sum_{j=1}^N |Q_j| - m(E) \right)$

On the right side of the whiteboard, there is a Venn diagram with two overlapping circles labeled E and F . The region $E \setminus F$ is shaded green, and the region $F \setminus E$ is shaded orange. Arrows point from the text to these regions.

Additional notes on the right side of the whiteboard include:

- $E \setminus F \subseteq \bigcup_{j=N+1}^{\infty} Q_j$
- $F \setminus E = \bigcup_{j=1}^N Q_j \setminus E$
- $\subseteq \bigcup_{j=1}^N Q_j \setminus E$

So, just take the remaining to be your F , take capital F to be union Q_j , j equal to 1 to N . The remaining is sort of taken care here, whatever remaining you in the union you take it to be F . So, F is a, so this is the union of finite union of, finite union of closed cubes, closed cubes and you want to say F approximate claim, is that claim is that, measure of $E \Delta F$ is small is less than ϵ less than or equal to. Let us see, why?

So, measure of $E \Delta F$, well what will be this? This is a measure of $E \Delta F$ is $E \setminus F$ union $F \setminus E$, that is the definition of the symmetric difference. But these are disjoint these are disjoint that is easy to see. So, if this is E and this is F , so let us say this is E and this is F , $E \setminus F$. This portion is $E \setminus F$ and this portion is $F \setminus E$.

So, they are disjoint, the intersection part does not there. So, because m is a measure this becomes m of $E \setminus F$ plus m of $F \setminus E$, which is less than or equal to measure of union j equal to N plus 1 to infinity Q_j . Let me explain write down and then explain plus m of union j equal to 1 to infinity $Q_j \setminus E$, let us see why?

So, I want to say that, so this is this is true because well. So, how does one prove this? This is true because $E \setminus F$ is contained in union j equal to n plus 1 to infinity Q_j . That is easy because E is contained in because E itself is contained in the full union j equals 1 to infinity Q_j and you are throwing out the first N by subtracting F .

Similarly, $F \setminus E$, So, what is $F \setminus E$, this is j equal to 1 to N , $Q_j \setminus E$, of course, will be contained in j equal to 1 to infinity $Q_j \setminus E$, you are taking a much bigger set. So, this is true and this is a of course less than or equal to I can apply sub additivity here. So, I will get summation j equal to N plus 1 to infinity m of Q_j simply the volume of Q_j . m of $Q_j \setminus E$ star of Q_j equal to modulus, mod Q_j plus summation j equal to 1 to infinity remember these are all finite $Q_j \setminus m$ of E . So, this has to be justified. So, I am, saying this portion is less than or equal to whatever is written here. So let me write down that.

(Refer Slide Time: 22:36)

So, this is because m of union j equal to 1 to infinity Q_j , Q_j minus E is less than or equal to summation j equal to 1 to infinity $|Q_j|$ minus m of E . Why is this true? Everywhere we have finite quantities. So, let us take two sets A and B , let us say m of A , m of B are finite. Then if you look at m of A minus B , this I can write this as... So, start with m of A I write it as m of A minus B . So easy, easy things.

So, A is contained in A minus B union B and so m of A will be less than or equal to m of A minus B plus m of B . So, use that you will get this one. So, now from here it follows that. So, if I look at the LHS and the RHS remember this portion is less or equal to ϵ by 2. And this is also less than or equal to ϵ by 2 because that is the way we have chosen Q_j .

So, we have chosen Q_j with this property. So, both of them put together will give me that hence we get $m(E \Delta F)$, to be less than ϵ , so that finishes the proof.

(Refer Slide Time: 24:43)

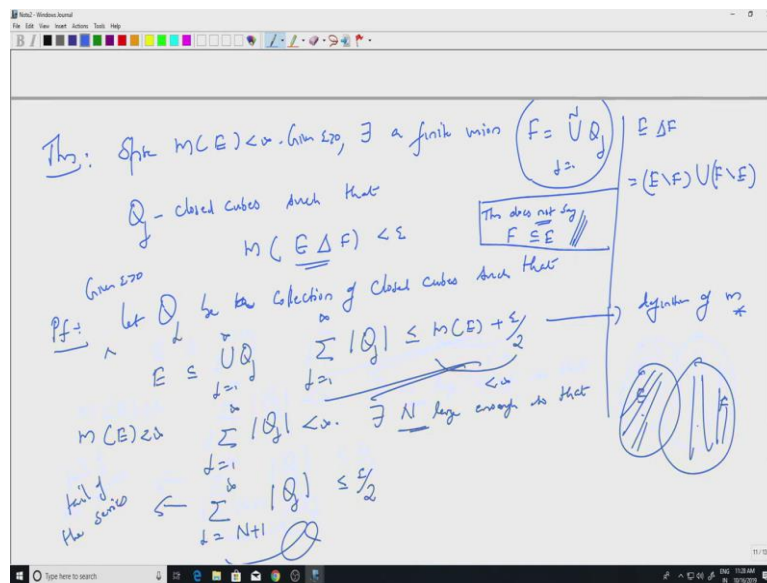

$m(\Omega \setminus E) < \epsilon$
 $E \subset \Omega$
 $\forall \epsilon > 0 \exists$ a closed set $F \supset E$
 $m(E \setminus F) < \epsilon$
 $m(E \setminus K) < \epsilon$
 This is trivial if E is both F -closed and $F \subset E \Rightarrow F$ is not
 Exact Contradiction
 $E \supset F \Rightarrow E \setminus F \neq \emptyset$
 such that $m(E \setminus F) < \epsilon$ and E is unbounded
 This: Spite $E \in \mathcal{L}(\mathbb{R}^n)$ and $m(E) < \infty$
 Then $\forall \epsilon > 0 \exists$ a Compact set $K \subseteq E$ such that
 $m(E \setminus K) < \epsilon$
 Pft: $E \in \mathcal{L}(\mathbb{R}^n)$, $\forall \epsilon > 0 \exists F \subseteq E$ F closed such that
 $m(E \setminus F) < \epsilon$
 $F = \bigcup_{k=1}^{\infty} (F \cap B(0, k)) = \bigcup_{k=1}^{\infty} K_k$
 closed ball of radius k centered 0
 $K_k \subseteq F \subseteq E$
 $K \uparrow F$

This: Spite $m(E) < \infty$. Given $\epsilon > 0$, \exists a finite union $F = \bigcup_{j=1}^N Q_j$ $E \Delta F = (E \setminus F) \cup (F \setminus E)$
 Q_j - closed cubes such that $m(E \Delta F) < \epsilon$
 This does not say $F \subseteq E$
 Given $\epsilon > 0$
 Pft: let \mathcal{Q}_ϵ be the collection of closed cubes such that
 $E \subseteq \bigcup_{j=1}^{\infty} Q_j$ $\sum_{j=1}^{\infty} |Q_j| \leq m(E) + \frac{\epsilon}{2}$
 $m(E) < \infty$ $\sum_{j=1}^{\infty} |Q_j| < \infty$ $\exists N$ large enough so that
 $\sum_{j=1}^N |Q_j| < \frac{\epsilon}{2}$
 definition of m^*

So just to repeat, these two theorems are slightly finer properties of the measurable sets. So, here we have a compact set, which is both for sets of finite measure. So, here we have a compact set and we have an inclusion.

Here we have, we do not have a compact we have a compact set, but the compact set is much more explicit in the sense that it is actually union of closed cubes, but then we do not have this portion that F , F need not be contained in E unlike here K contained in E . So, that is that is the point you should understand.

(Refer Slide Time: 25:25)

But then the conclusion is that if you take the symmetric difference right. So, E is like this f is like F can be like this. So, if E is this and F is this, then the symmetric difference is this part that is very small which means that F and E are very close to each other.

So, E can be approximated by union of intervals. So, that is what we have. So, this is a good point to stop. So, what we have done so far is complete the construction of the Lebesgue measure and look at certain finer properties of the measurable sets. So, the measurable sets in \mathbb{R}^n Lebesgue measurable sets in \mathbb{R}^n can be approximated from inside by compact sets if those sets are sets of finite measure, and if and also you can change the compact set by a union of close cubes, finite union of close cubes.

And this would be very close to the original set original Lebesgue measure set provided the set has a finite measure. So, sets of finite measure can be approximated by sets, the kind of sets you want from what you see from topology and so on. So, we will go ahead with those in the next session as well and see that they do not differ too much from Borel set.

So, if you look at compact sets, they are Borel sets they are closed sets, so they are Borel sets. Similarly the union of closed cubes you have seen there also Borel set. So, we are trying to say that Lebesgue set is very close to a bottle sets and that is how we prove that the Lebesgue sigma algebra is the completion of the Borel sigma algebra. So, we will take up that in the next sessions.
