**Invariance Properties of Lebesgue measure**

So we have constructed the Lebesgue measure completely now. So, we have  $\mathbb{R}^n$  we have the Lebesgue sigma algebra over  $\mathbb{R}^n$  and the Lebesgue measure on  $\mathbb{R}^n$  and we looked at some finer properties of the measurable sets.

Today will first look at some properties, some invariants properties of the Lebesgue measure itself and then we will, we will see that any Lebesgue set is can be approximated by Borel set very closely in fact, the Lebesgue sigma algebra is the completion of the Borel sigma algebra with respect to the Lebesgue measure. So that is what we will do in the first session, then we will go on to look at non measurable sets and things like that. So we will start with some invariants properties of the Lebesgue measure.

(Refer Slide Time: 1:19)

$(\mathbb{R}^n, \mathcal{L}(\mathbb{R}^n), m)$      $\mathcal{B}(\mathbb{R}^n) \subseteq \mathcal{L}(\mathbb{R}^n) \subseteq 2^{\mathbb{R}^n}$   
 Invariance properties of Lebesgue measure on  $\mathbb{R}^n$ :  
 I) Translation:  $E \subseteq \mathbb{R}^n$      $h \in \mathbb{R}^n$      $E+h = \{x+h \mid x \in E\}$   
 Result:  $E \in \mathcal{L}(\mathbb{R}^n)$ ,  $h \in \mathbb{R}^n$   
 Then  $E+h \in \mathcal{L}(\mathbb{R}^n)$  and  
 $m(E+h) = m(E)$   
Pf:  $m(E) = m_*(E)$

Diagram: A set  $E$  (shaded) is translated by a vector  $h$  to a set  $E+h$  (unshaded). A number line below shows intervals  $[0, 1]$ ,  $[1, 2]$ ,  $[2, 3]$  and their translation  $E+2 = [2, 3] \mid x \in E = [x, x+2]$ .

Result:  $E \in \mathcal{L}(\mathbb{R}^n)$ ,  $h \in \mathbb{R}^n$   
 Then  $E+h \in \mathcal{L}(\mathbb{R}^n)$  and  
 $m(E+h) = m(E)$   
Pf:  $m(E) = m_*(E)$   
 $= \inf \left\{ \sum_{j=1}^n |Q_j| \mid \begin{array}{l} Q_j \text{ closed cubes} \\ E \subseteq \bigcup_{j=1}^n Q_j \end{array} \right\}$

Diagram: A set  $E$  (shaded) is translated by a vector  $h$  to a set  $E+h$  (unshaded). A number line below shows intervals  $[0, 1]$ ,  $[1, 2]$ ,  $[2, 3]$  and their translation  $E+2 = [2, 3] \mid x \in E = [x, x+2]$ .

So, recall we have the space  $\mathbb{R}^n$ , we have the Lebesgue sigma algebra and the Lebesgue measure. So, also recall that we have the Borel sigma algebra  $\mathcal{B}$  of  $\mathbb{R}^n$  and that is of course contained in the Lebesgue sigma algebra we know that, and which is of course, contained in the power set.

And yesterday I had mentioned that the inclusions are strict, okay. So, we will construct examples to show that these inclusions are strict. So, we start with some invariants properties of the Lebesgue measure, invariance properties of Lebesgue measure on  $\mathbb{R}^n$ . So, this gives an idea about how the Lebesgue measure interacts with various natural operations on  $\mathbb{R}^n$ .

So the first one is translation invariant, translation invariance. So, let us just look at translation. So what is translation? Translations, is if I take a set  $E$ , let us say subset of  $\mathbb{R}^n$ .

So, we are not assuming it will be measurable now, and some vector  $h$  in  $\mathbb{R}^n$  then we can define  $E + h$  this is translating  $E$  by  $h$ .

So, how is this defined, this is defined to be all  $x + h$ , where  $x$  belongs to  $E$ . So, we are simply translating the set. So, if the set  $E$  is like this and depending on where  $h$  is you will get  $E + h$  to be somewhere here have the same shape. So, when I drew the shape will change, but shape change, but it is exactly the same.

So, an easy example would be on the real line. So, let us look at the interval  $[0, 1]$  and translate... So, let us say this is  $E$ , translated by a number 2. So, let us see what is  $E + 2$  is. So,  $E + 2$  will be all  $x + 2$ , where  $x$  belongs to  $E$ ,  $E$  is the closed interval  $[0, 1]$ . When I add 2 it, I am going to get the interval  $[2, 3]$ .

So, this is simply translating  $E$  to this interval to you, you translate this by two and when you translate of course, you see that the length of the interval does not change and this is true for cubes as well in  $\mathbb{R}^n$ . So, when you translate the measure should not change. So, that is a first assertion.

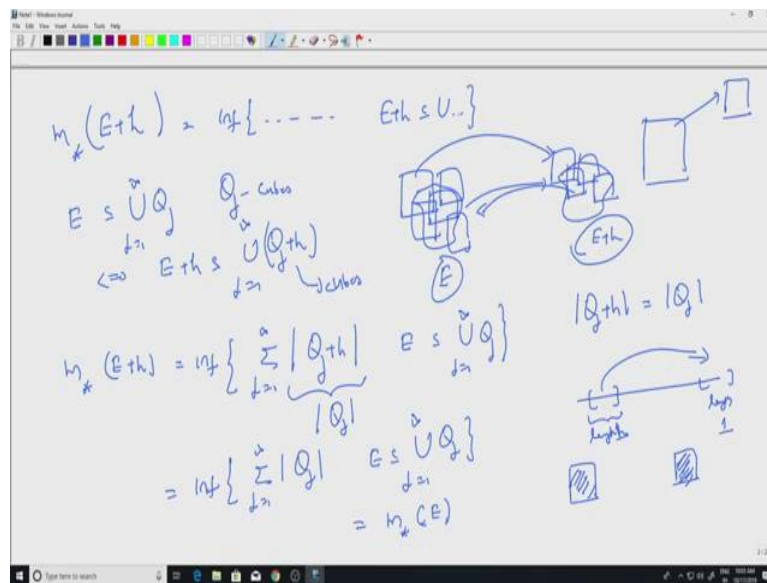

So, let us prove that. So, let me write this as a result these are easy results but it is, these are very important results as well. So, if I take a measurable set  $L$  of  $\mathbb{R}^n$ ,  $E$  in Lebesgue set then and so you fix a vector in  $\mathbb{R}^n$  fix a vector  $h$  in  $\mathbb{R}^n$ , then first of all  $E + h$  is also measurable.

That is one assertion and the measure does not change. So, measure of  $E + h$ , so translated set and the measure of  $E$  are same, so to say  $m$  of  $E + h$ , one needs to know that  $E + h$  is in  $L$  of  $\mathbb{R}^n$  and. So, that is the first assertion and then we say that the measures are same. Well, proof is very simple, but let us, let us do this in a slightly elaborate manner, because the other invariance properties will be of the similar kind.

So, first thing is let us recall what is the measure. So,  $m$  of  $E$  is  $m^*$  of  $E$ . So, it is the outer measure of  $E$  only thing  $E$  is, if  $E$  is in the Lebesgue sigma algebra, we say  $m$  of  $E$ . So, let us keep that in mind, which is equal to the infimum of various quantities which we have seen so many times by now  $\sum_{j=1}^{\infty} |Q_j|$  equals 1 to infinity  $Q_j$  are closed cubes, closed or open does not really matter, closed cubes and more importantly  $E$  is covered by  $Q_j$ .

And then you take the infimum of these quantities. Well it is very easy to see that. So, for  $m^*$ ,  $m^*$  is defined on the power set of  $\mathbb{R}^n$ . So,  $m^*$  of  $E$  is defined for every set  $E$  we do not need to bother about any measurability properties.

(Refer Slide Time: 06:30)

So if you look at  $E$  plus  $h$  and  $m$  star of that, well, what is this? This is of course infimum of various quantity, so I am not going to write this, so the only condition is  $E$  plus  $h$  is contained in whatever union you are taking.

Well, so how does it look like? So let us say  $E$  is here and  $E$  plus  $h$  here. So, if I have cubes, covering  $E$  like this and I translate  $E$  to get  $E$  plus  $h$ . If I translate these cubes, I will get a cover for  $E$  plus  $h$  and similarly, if I translate back by minus  $h$ , I will get a cover for  $E$ . So, covers for  $E$  plus  $h$  can be translated to covers for  $E$  and vice versa.

So, what I want to say is, if I have  $E$  contained in union of  $Q_j$   $j$  equal to 1 to infinity to  $Q_j$  are cubes. So, if you translate a cube you are going to get another cube. So, if I translate this by some vector, I am going to get something similar. So, that is that is a cube. Then, well you can say if and only if  $E$  plus  $h$  is covered by the cubes translated.

So, these are also cubes  $Q$  plus  $Q$  plus  $h$  cubes. So, because of that  $m$  star of  $E$  plus  $h$  is equal to infimum of summation  $j$  equal to 1 to infinity volume of all those  $Q_j$  which cover  $h$ . So, you translate them. So, now you get a cover for  $E$  plus  $h$  such that  $E$  is contained in union  $Q_j$ ,  $j$  equal to 1 to infinity.

But what is  $Q_j$  plus  $h$ , the volume of  $Q_j$  plus  $h$ , volume of  $Q_j$  plus  $h$  is same as volume of  $Q_j$ , if you translate you do not change the volume. So, look at the easy example, if I have an interval of length 1, length 1, I translate it to any place I want. I will still get a interval of length 1. So if I translate, I am not going to change the volume of the cube. If I have a square

in  $\mathbb{R}^2$ , I translated I am going to get the same square, but the area of the square will position will change, but the area is going to be the same.

So, this is simply  $m^* E = \inf_{j=1}^{\infty} \sum_{j=1}^{\infty} m(Q_j)$ . So, this is the same as infimum of  $\sum_{j=1}^{\infty} m(Q_j)$  where  $E$  is contained in union  $j=1$  to infinity  $Q_j$  where  $Q_j$  are cubes, but this is the definition of  $m^*$  of  $E$ . So, this is a trivial computation we have done, but it shows that  $m^*$  of  $E+h$  is same as  $m^*$  of  $E$ . So,  $m^*$  is translation invariant if you translate the set you are not going to change the value of  $m^*$ . So, but it does not prove that  $m^*$  that  $E+h$  is measurable. So, we need to follow that as well.

(Refer Slide Time: 10:10)

$$= \inf_{\{Q_j\}} \sum_{j=1}^{\infty} m(Q_j) = m^*(E)$$

Spce  $E$  is mble.  $\forall \epsilon > 0 \exists$  an open set  $O$  such that  
 $m^*(O) < \epsilon$   
 $m^*(O+h) = m^*(O) < \epsilon$   
 $m^*(O+h) \setminus E+h = m^*(O+h) = m^*(O) < \epsilon$   
 $\Rightarrow E+h \in \mathcal{L}(m^*)$   
 $m(E+h) = m^*(E+h) = m^*(E) = m(E)$

$A \cap B = A \cap B^c$   
 $(A+h) \setminus (B+h) \subset (A+h) \cap (B+h)^c = (A+h) \cap (B^c+h) = (A \cap B^c)+h$

Result:  $E \in \mathcal{L}(m^*), h \in \mathbb{R}$   
 then  $E+h \in \mathcal{L}(m^*)$  and  
 $m(E+h) = m(E)$

Pf:  $m(E) = m^*(E)$   
 $= \inf_{\{Q_j\}} \sum_{j=1}^{\infty} m(Q_j)$  where  $Q_j$  are closed cubes  
 $E \subset \bigcup_{j=1}^{\infty} Q_j$

$E = [0, 1] \cup [2, 3]$   
 $E+h = [2, 3] \cup [4, 5]$

So, suppose  $E$  is measurable, suppose  $E$  is measurable. What does that mean? So for every epsilon positive there exist an open set open set,  $O$ , such that, such that the outer measure of

$O$  minus  $E$  is less than  $\epsilon$ . This is what measurability makes. So, what we have is  $E$  a set here and some  $O$  ones around it. That is my  $O$ , I am trying to prove that  $E$  plus  $h$  is measurable.

So I simply translate this open set  $O$ , by it, so I will get  $O$  plus  $h$  and whatever is the difference over the differences is simply translated by  $h$ . So,  $m^*$  of  $O$  plus  $h$ ,  $O$  plus  $h$  is a set minus  $E$  plus  $h$  well, what is this, this is  $m^*$  of  $O$  minus  $E$  plus  $h$  well, you need to verify this, this is a trivial, trivial thing, but remember the minus here is the set theoretic minus.

So, let me, let me write it down for  $A$  and  $B$ , suppose I have two sets  $A$  and  $B$  I look at  $A$  minus  $B$ , what is  $A$  minus  $B$ ? That is  $A$  intersection  $B$  complement. Now,  $A$  plus  $h$  as a set minus  $B$  plus  $h$ . So, another set well what will this be? So this is  $A$  plus  $h$ . By definition intersected with  $B$  plus  $h$  whole complement.

So, you need to check that this is actually equal to  $A$  intersection  $B$  complement translated by  $h$ . So, that is what of trivial from the, from the pictures, but you can write down a proof if you want. So, go back to  $m^*$  of  $O$  plus  $h$  minus  $E$  plus  $h$ , that is  $m^*$  of  $O$  minus  $E$  plus  $h$ , which is equal to. So, we just proved that  $m^*$  is translation invariance.

So, that is same as  $m^*$  of  $O$  minus  $E$ , which I know is less than  $\epsilon$  and the fact that  $O$  plus  $h$  is open. If I translate an open set, I am going to get an open set. So, what we have proved just now is given an  $\epsilon$ , there is an open set  $O$  plus  $h$  such that  $m^*$  of  $O$  plus  $h$  minus  $E$  plus  $h$  is less than  $\epsilon$ .

So, that implies that the set  $E$  plus  $h$  is also measurable,  $E$  plus  $h$  is measurable and so  $m^*$  of  $O$  plus  $h$  is  $m$  of  $E$  plus  $h$ . That is simply the definition, so  $m$  of  $E$  plus  $h$  that makes sense to write  $m$  of something, that something has to be measurable sets. This is equal to, I know it is equal to  $m^*$  of  $E$  because  $m^*$  is trivially invariant and the translation and this is equal to  $m$  of  $E$ .

This is precisely the result asserted here. So let me yeah, so here, we claimed that  $E$  plus  $h$  is measurable and the measures are same. So Lebesgue measure is translation invariant if I if I translate something, I am not going to change the measure of the set. So that is the first property we have seen.

(Refer Slide Time: 14:10)

$m(\delta E) = \delta^n m(E)$   
 $= (A \cap B^c) + h$

2) Dilation : let  $\delta > 0$   
 $E \subset \mathbb{R}^n$   
 $\mathbb{R}^n \rightarrow \mathbb{R}^n$   
 $x \rightarrow \delta x$   
 $\delta E = \{ \delta x \mid x \in E \}$

$x = (x_1, x_2, \dots, x_n)$   
 $\delta x = (\delta x_1, \delta x_2, \dots, \delta x_n)$

$\mathbb{R}^2$   
 $(0,0)$   $(\delta, \delta)$   
 $(0, \delta)$   $(\delta, 0)$

Multiply by  $\delta$   
 $m(\delta E) = \delta^n m(E)$   
 $m(E) = 1$

$E \subset \mathbb{R}^n$   
 $\delta E = \{ \delta x \mid x \in E \}$

$\mathbb{R}^2$   
 $(0,0)$   $(\delta, \delta)$   
 $(0, \delta)$   $(\delta, 0)$

$m(E) = 1$   
 Multiply by  $\delta$   
 $m(\delta E) = \delta^n m(E)$   
 $m(E) = 1$

let  $\delta > 0$   
 $\delta E$

$(0,0)$   $(\delta, \delta)$   
 $(0, \delta)$   $(\delta, 0)$

$m(\delta E) = \delta^n m(E)$

Second, second property, second invariance, this is with respect to dilation, dilation. So, what is dilation? So you start with let some take some positive quantity delta, greater than 0 and you multiply by delta. So, you are looking at the map from  $\mathbb{R}^n$  to  $\mathbb{R}^n$   $x$  going to  $\delta x$ , that makes sense. So, remember  $x$  is a tuple  $x_1, x_2, \dots, x_n$   $\delta x$  would be, you multiply all of them  $\delta x_1, \delta x_2, \dots, \delta x_n$  usual vector space operations.

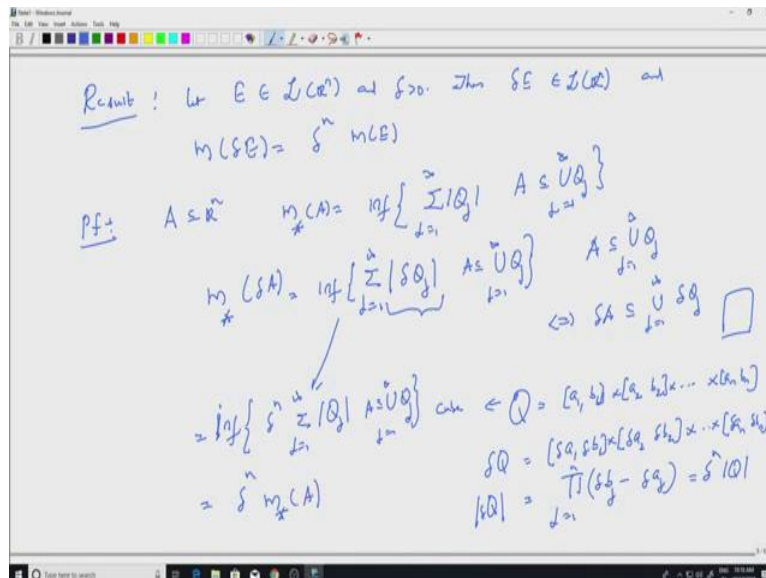

This one and this you can do for sets right if I take a set  $E$  contained in  $\mathbb{R}^n$ , I can define  $\delta E$  to be  $\delta x$ , where  $x$  belongs to  $E$  just like what we did for translation. Now we want to say a similar, similar result hold for dilation of course Lebesgue measure will not preserve dilation that is easy to see. So let us, let us look at some example to guess what should be the answer.

So let us take the interval  $01$  in  $\mathbb{R}$ . Let us multiply it by four. So, multiply by, let us say  $4$ . So, I will get, if I multiply by  $4$ , I am going to get so I will draw it here  $0$  to  $4$  that is the interval. So, if this is  $E$ , this would be  $4E$ . What is the Lebesgue measure of  $E$ ? That is one because it is an interval, so the length is  $1$  and if I look at the measure of  $4E$ , I am waiting  $4$  times measure of  $E$ .

So, whatever you are multiplying by it comes out. But let us look at  $\mathbb{R}^2$  and look at another example. So, let us take this unit, unit square  $01$  here. So, this is my set  $E$ , if I multiply it with the  $\delta$ . So, let  $\delta$  be positive and we multiply this with  $\delta$ . So, how will  $\delta E$  look like? Well that is also a square, it is cornered at  $00$  of course, but these coordinates become  $\delta$  zero,  $\delta$   $\delta$  and zero  $\delta$ .

What is measure of  $E$ , the two dimensional Lebesgue measure of  $E$ ? This is  $1$  this is the area of this square. Measure of  $\delta E$  this is  $\delta E$ , measure of  $\delta E$  is the area of the square. So I have  $\delta$  here, I have  $\delta$  here. So, that is  $\delta$  square  $\delta$  square into measure of  $E$ . So, this time so instead of  $4$  here I have  $\delta$  square, it is not  $\delta$  because the two depends on the dimension. Similarly, if you got to  $\mathbb{R}^3$ , you will see that  $\delta$  cube comes out.

(Refer Slide Time: 17:33)

So the result we want the state is, result, let  $E$  be a measurable set  $L$  of  $\mathbb{R}^n$  and  $\delta$  be positive, then, well, first of all,  $\delta E$  is measurable. So, that we can talk about its measure and  $L$  of  $\mathbb{R}^n$  and the measure of  $\delta E$  is actually equal to  $\delta^n$  times measure of  $E$ . So, the  $n$  comes from the dimension of  $\mathbb{R}^n$  times measure of  $E$  that is what happens. So, let us prove this. So, as

earlier, we will look at  $m^*$  of something and see how the multiplication by  $\delta$  acts on it or the effect of multiplication by  $\delta$  on  $m^*$ .

So, let us go back to general set  $A$  subset of  $\mathbb{R}^n$ ,  $m^*$  of  $A$  by definition is the infimum. We have seen this so many times now  $m^*(A) = \inf_{\{Q_j\}} \sum_{j=1}^{\infty} \text{mod } Q_j$ ,  $j$  the equal to 1 to infinity  $A$  is contained in union  $Q_j$ . Now what is  $m^*(\delta A)$ ? Well, this is infimum of some collections, what are those collection? So, just like what we did earlier, we see that  $A$  is contained in union  $Q_j$ ,  $j$  equal to 1 to infinity if and only if  $\delta A$  is contained in union  $j$  equal to 1 to infinity  $\delta Q_j$ .

So, all you have to do is to dilate the cubes accordingly to cover  $\delta A$ . So, this would be infimum of summation  $j$  equal to 1 to infinity modulus  $\delta Q_j$ . Where  $Q_j$  is covers  $A$ . So,  $A$  is contained in union  $Q_j$   $j$  equal to 1 to infinity. So, you take any such cover multiply by  $\delta$  you will get a cover of  $\delta A$  you take any cover of  $\delta A$  divided by  $\delta$  you will get a cover of  $A$ .

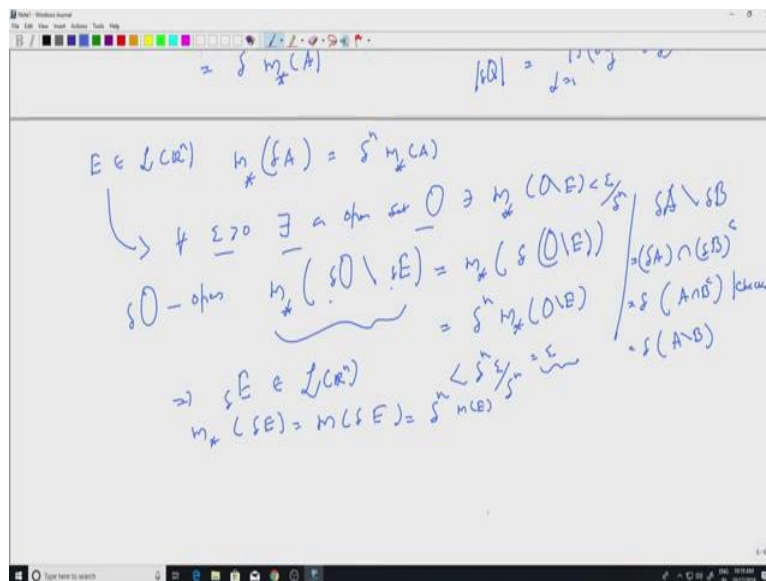

So, that is why this is 2, the collection of cubes have to be the same essentially apart from multiplication by  $\delta$  well. But what is this? Well, for cubes, it is easy to compute. So, let us let us see, if I take a cube  $Q$ , so cube let us say closed cube this of course is product of intervals  $a_1, b_1, a_2, b_2$  etc, etc  $a_n$  and  $b_n$ .

So, it looks like something like this in  $\mathbb{R}^2$ . You multiply by  $\delta$ . But of course, you are going to multiply each of them  $a_1 b_1$  cross  $\delta a_2 \delta b_2$ ,  $\delta$  is positive remember, cross  $\delta a_n \delta b_n$ . So, what is the volume of  $\delta Q$ ? Well, you look at the product of the sides. So, that is  $\delta b_j$  minus  $\delta a_j$   $j$  equal to 1 to  $m$ .

So, from each component that  $\delta$  comes each side has got dilated by  $\delta$ . So, the side changes by  $\delta$  and from each component you get  $\delta$ . So, this is  $\delta$  to the  $n$ , times whatever remains is the measure of  $Q$ . So, for cubes this is trivial and that is why it becomes true for all other sets as well.

So this from here, I will get that this is equal to infimum of I will get  $\delta$  to the  $n$  outside summation  $j$  equal to 1 to infinity mod  $Q_j$  and  $A$  is contained in union  $Q_j$ ,  $j$  equal to 1 to infinity. But the  $\delta$  to  $n$  will come out, it is a positive quantity and you are taking the infimum of the remaining which is simply  $\delta$  to the  $n$  times measure of  $E$  measure of  $A$   $m^*$  of  $A$ , the outer measure of  $A$ .

(Refer Slide Time: 22:10)

So we apply all this this, to the result we want to prove. So, we started with  $E$  belonging to  $\mathcal{L}$  of  $\mathbb{R}^n$ . Again, we do not know what happened to  $\delta A$ , but we know that the  $m$  star the outer measure of  $\delta E$  is  $\delta m$  to  $m$  star of  $E$ , this we know and this we know and well let me write it for general set. So, that we can use it for different sets, so  $A$  and  $A$  this we know. Now  $E$  is measurable implies for every  $\epsilon$  positive, there exist an open set open set  $O$  such that the measure of  $O$  minus  $E$  is less than  $\epsilon$  this we know.

Well, what should we do to get an open set around  $\delta E$  well we look at  $\delta O$ . So,  $\delta O$  is open and  $m$  star of  $\delta O$  minus  $\delta E$ , well, what is this this is  $m$  star of. So, again trivial verification to be checked is this. So, what did we use, we use that  $\delta A$  minus  $\delta B$ , well this is  $\delta A$  intersected with  $\delta B$  whole compliment, this is nothing but  $\delta(A \cap B^c)$ .

So, this is what you have to check the trivial thing equal to  $\delta(A \cap B^c)$ . So, that is what we have used and we know that  $m$  star when you dilate  $m$  star as the property that  $\delta$  to the  $n$  comes out. So a measure of  $O$  minus  $E$ , which is less than  $\delta$  to the  $n$  times  $\epsilon$ . That is also enough, so if you want to be very, very precise, for every  $\epsilon$  there exists and open set  $O$  such that  $m$  star  $O$ ,  $m$  star  $O$  minus  $E$  is less than  $\epsilon$  by  $\delta$  to the  $n$ , you can start with that.

So that will give me  $\delta O$  minus  $\delta E$  is  $\delta^n$  times this is equal to  $\epsilon$ . So this inequality implies that  $\delta E$  is measurable and of course, if it is measurable, then we

know that  $m^*$  of  $\delta E$  well, this is actually  $m$  of  $\delta E$  equal to  $\delta$  to the  $n$  times  $m$  of  $E$ . This we know, because that is a property of  $m^*$ .

So, that proves this result. So, this result is proved. So, Lebesgue measure is translation invariant with respect to dilation, it gives me a factor of  $\delta$  to the  $n$ . That is expected and well there is one more result. So, I will not prove this in as much details as we just did, but because this is much more easy.

(Refer Slide Time: 25:23)

Three reflection well, what is reflection? Reflection is the map  $x$  going to  $-x$ . So, this is a map from  $\mathbb{R}^n$  to  $\mathbb{R}^n$ . So, the result we want to state is, suppose,  $E$  belongs to  $\mathcal{L}$  of  $\mathbb{R}^n$  and then its reflection is  $-E$ ,  $-E$  equal to well what is this this is  $-x$  where  $x$  belongs  $E$ .

That is the reflection, so in the case of real line, suppose I take an interval here, let us say  $a, b$ , this is my set  $E$  then,  $-E$  will be  $b-1$  to  $a-1$  this would be  $-E$  and of course, the length does not change, if I take a cube  $Q$  in  $\mathbb{R}^n$  cube then  $-Q$  is also a cube, this is also a cube more importantly,  $-Q$  has the same side length.

So, the volume will be the same and so  $m^*$  will respect this. So,  $m^*$  will, will not change when you take the negative of  $-Q$ . So,  $m^*$  of  $E$  and  $m^*$  of  $-E$  will be same. So, easy to verify. So I will leave it to you. Easy to verify that  $m^*$  of  $E$  is same as  $m^*$  of  $-E$ .

So, this is because any cube  $Q$  and its negative  $-Q$ , what it means is will have the same volume. So, when you take the infimum it is not going to change. So, any cover of  $E$  you can take  $-$  of that will get a cover of  $-E$  and the corresponding quantities are same.

So, because of those, if  $E$  is measurable if  $E$  is measurable then of course, so for every  $\epsilon$  positive that exists and open set  $O$  such that  $m^*$  of  $O \setminus E$  is less than  $\epsilon$ . So, you can change everything to  $-E$  now.

So, this would imply that you look at  $-O$ ,  $-O$  is open set this is an open set and  $m^*$  of  $-O \setminus -E$ . So, remember there are two minuses the slanted minus is the set theoretic minus. So, if you look at  $-A \setminus -B = -A \cap B$  intersection

minus  $B$  whole complement and you prove that this is actually equal to  $A$  minus  $B$  minus of that.

So, this is equal to  $m^*$  of minus of  $O$  minus  $E$  and we have seen that when you take minus nothing happens to  $m^*$ . So, that is  $m^*$  of  $O$  minus  $E$  which is less than  $\epsilon$ , which is precisely the statement that minus  $E$  is also measurable implies minus  $E$  belongs to  $L$  of  $\mathbb{R}$ . So, I started with  $E$  in  $L$  of  $\mathbb{R}$  I have minus  $E$  in  $L$  of  $\mathbb{R}^n$  and of course,  $m^*$  of  $E$  and  $m^*$  of minus  $E$  are same. So,  $m$  of  $e$  and  $m$  of  $E$  and  $m$  of minus  $E$  are same.

So, let me stop with some remarks. We have just seen three invariants properties of the Lebesgue measure it is translation invariant with respect to dilation, we have a certain different kind of invariants and it is reflection invariants. You will notice that these the last two examples, the dilation and the reflection. These are linear maps from  $\mathbb{R}^n$  to  $\mathbb{R}^n$ . And so you can ask the question how does the Lebesgue measure deal with? Or how does it behave with linear transformations on  $\mathbb{R}^n$ ?

So a general result we will state later and improve if I, because there are certain things to be established before we can state the, state the result if you, if you translate or if you apply a linear transformation to a measurable set, we have proved that it has measurable and its volume or it is, it is a Lebesgue measure would be the determinant of the linear transformation times the measure of the original set.

And that is precisely what do you have seen in the case of multiplication by  $\delta$ . So, multiplication by  $\delta$  is a linear transformation whose determinant is  $\delta^n$ , and  $x$  going to minus  $x$  is another linear transformation whose determinant is one. So that does not show up here. So we will stop here, continue.
