Properties of countably additive measures

So what we have proved so far is that if I have a positive measurable function I have a increasing sequence of simple functions converging to that function at all points, so now our aim would be to define integration of positive functions first but before that will look at some properties of a countably additive measure.

(Refer Slide Time: 00:58)

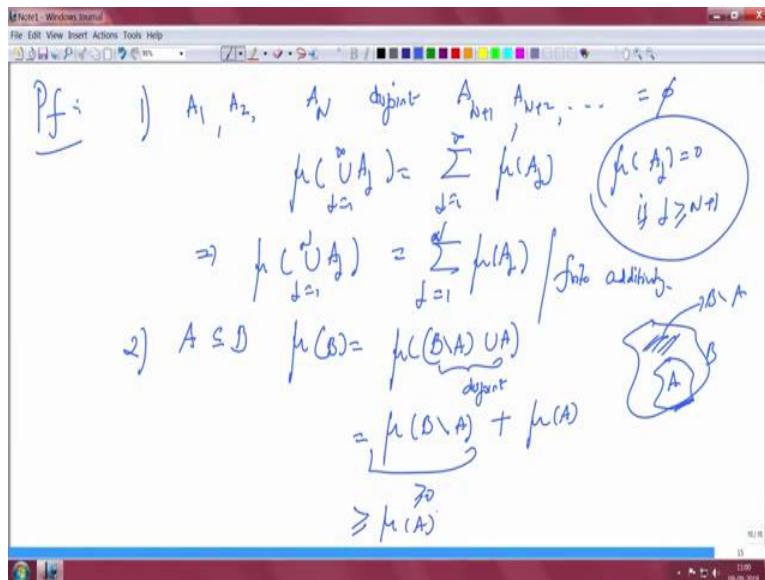

So let us recall that, so I have this space X and the sigma algebra F, so Mu was a measure as a countably additive measure so recall that Mu of union A j, j equal to 1 to infinity equal to summation Mu of A j, j equal to 1 to infinity if A j are disjoint okay so this is the countable additive measure okay. If you have such a measure there are certain properties of Mu which we require, so let me write as a theorem, okay.

Mu of union A j, j equal to 1 to n so now I am only taking finite union so that is the sum of Mu of A j, j equal to 1 to n if A j are disjoint, so even for finite disjoint union we have so that is not surprising because we know that for infinite it is true if A is contained B then Mu of A is less than to Mu of B, so this is called monotonicity, so ofcourse the sets A and B are all in the sigma algebra otherwise Mu of that is define, remember the Mu is defined in the sigma algebra F.

So the sets wherever we write μ of A it is assumed that set A is in script \mathcal{F} , if A_n s are increasing so let us say A_n s are measure sets and A_n s are increasing so A_1 is contained in A_2 contained in A_3 etc. okay, so they will converge to some set A right and A is the union A_j , j equal to 1 to n , 1 to infinity then μ of A_n , so μ of A_n are positive numbers right that will increase to μ of A , okay. So in other words if A_n increases to A then μ of A_n increases to μ of A , so let us prove that, okay.

(Refer Slide Time: 03:49)

So proof, okay, so in the first one we have A_1, A_2 etc A_n disjoint right disjoint I can take A_{n+1}, A_{n+2} etc. all to be equal to empty set. So I have now infinity, right. so I know that they are all disjoint, so I know that μ of A_j , j equal to 1 to infinity is equal to some of μ of A_j , j equal to 1 to infinity by a countable additivity property of the measure. But μ of A_j is 0 if j is greater than or equal to $n+1$.

Because they are all empty sets, so here in the left hand side I will have only union up to n because $n+1$ onwards they are empty sets so it does not add anything to it and here when I look at the summation, summation j equal to 1 to n I will have μ of A_j some numbers but then whatever remaining is 0 because of this, right because they are empty sets, so this is called the finite additivity.

So countable additivity implies finite additivity that is of course true, for the second one I have A and B so set A is contained in B , so B is bigger so it should have bigger measure right that is

what we want to prove. So let us see, so μ of $B \setminus A$ can write as μ of B minus μ of A union A right, so let us say this is B and some set A is inside right, so A is contained in B . So I am writing B as $B \setminus A$, so this is the part B minus A and A .

So this is the disjoint union and so it will add up right, the measure will add up, so this is simply $\mu(B \setminus A) + \mu(A)$ but $\mu(B \setminus A)$ is something which is positive, sorry $\mu(B \setminus A)$ is something which is positive. So this tells me that this is greater than or equal to $\mu(A)$ okay that is called the monotonicity property.

Now third property, so third property is very important, this is important, so if A_n (converge) so this is essentially equivalent to we can write another property for decreasing sequences and they are equivalent to μ being countably additive, so I will explain that after the proof of this, so let us look at three, okay.

(Refer Slide Time: 06:54)

$\textcircled{3} \quad A_n \uparrow A \quad (A_1 \subseteq A_2 \subseteq A_3 \subseteq \dots)$

$A = \bigcup_{j=1}^{\infty} A_j$

$A = A_1 \cup A_2 \cup A_3 \cup A_4 \cup \dots$

disjoint union
 $\left[= A_1 \cup (A_2 \setminus A_1) \cup (A_3 \setminus A_2) \cup \dots \cup (A_n \setminus A_{n-1}) \cup \dots \right]$

$\mu(A) = \mu(A_1) + \mu(A_2 \setminus A_1) + \mu(A_3 \setminus A_2) + \dots$

Assume that $\mu(A_j) < \infty \quad \forall j$ then $\mu(A_n \setminus A_{n-1}) = \mu(A_n) - \mu(A_{n-1})$

by $\mu(A_k) = \infty$ for some k then $\mu(A) \geq \mu(A_k) \Rightarrow \mu(A) = \infty$

Diagram: A large circle labeled A_4 contains several smaller nested circles labeled A_1, A_2, A_3 . The region between A_2 and A_3 is shaded, representing the disjoint union decomposition.

$\Rightarrow \mu(\bigcup_{j=1}^{\infty} A_j) \stackrel{\text{finite additivity}}{=} \sum_{j=1}^{\infty} \mu(A_j)$

2) $A \subseteq B$ $\mu(B) = \mu(B \setminus A) + \mu(A)$

$\geq \mu(A)$

3) $A_n \uparrow A$ ($A_1 \subseteq A_2 \subseteq A_3 \subseteq \dots$) $A = \bigcup_{j=1}^{\infty} A_j$

$A = A_1 \cup A_2 \cup A_3 \cup \dots$

$A = A_1 \cup A_2 \cup A_3 \cup \dots$

$= A_1 \cup (A_2 \setminus A_1) \cup (A_3 \setminus A_2) \cup \dots \cup (A_n \setminus A_{n-1}) \cup \dots$

$\mu(A) = \mu(A_1) + \mu(A_2 \setminus A_1) + \mu(A_3 \setminus A_2) + \dots$

Assume that $\mu(A_j) < \infty \forall j$ then $\mu(A_n \setminus A_{n-1}) = \mu(A_n) - \mu(A_{n-1})$

$\mu(A) = \mu(A_1) + (\mu(A_2) - \mu(A_1)) + (\mu(A_3) - \mu(A_2)) + \dots = \lim \mu(A_n)$

by $\mu(A_k) = \infty$ for some k then $\mu(A) \geq \mu(A_k) \Rightarrow \mu(A) = \infty$

So what I have is A_n increasing to A , well what does that mean? That means I have the sets A_1 which is smaller than A_2 smaller than A_3 and so on and some of them may be equal and A is simply the largest one, right so that is simply the union of all them that is the limit of A , and I want to say that $\mu(A_n)$ converges to $\mu(A)$, so let us draw some pictures, so let us say this is A_1 okay this is A_2 , this is A_3 , A_3 is bigger than that A_4 is much bigger than that and so on, okay.

So these sets are not disjoint but I can disjointify them, how do I do that? I look at A_1 then I look at whatever is in between then whatever is in between here, whatever is in between here and so on, right. So I can write A which I know is $A_1 \cup A_2 \cup A_3 \cup A_4 \cup \dots$ etc - etc I can

write this as A_1 so that is the first one here, union whatever is in A_2 and not in A_1 , so I look at A_2 minus A_1 , okay.

Then I can write union A_3 , so whatever is A_3 but not in A_2 , okay etc - etc, so union A_{j+1} minus A_j union dot-dot-dot, well what is the advantage of this? This would be a disjoint union, okay and so when I look at μ of A this would be because this is disjoint and μ is a countably additive measure it will add up μ of A_1 plus μ of A_2 minus A_1 plus μ of A_3 minus A_2 plus etc-etc.

Now if any of them is infinite, if any so let us make a reduction so if μ of A_k is infinity for some k then μ of A is greater than or equal to μ of A_k because A is the union of A_j s and so this will also imply that μ of A is infinity. And so the both sides will be same okay, so we can assume that μ of A_j is finite for every j then what is μ of A_{j+1} minus A_j ? Well this would be equal to μ of A_{j+1} minus μ of A_j right, we did this earlier so let me remind you of that.

So we wrote μ of B equal to μ of B minus A plus μ of A if this and this are finite then I can take μ of A to this side, so I will get μ of B minus A to be equal to μ of B minus μ of A , so that is why we have this. Now if you plug it in this would be μ of A equal to μ of A_1 plus well what happens to μ of A_2 minus μ of A_1 , so this is μ of A_2 minus μ of A_1 plus well this becomes μ of A_3 minus μ of A_2 plus dot-dot-dot. So notice that this cancels with this, this cancels with this, etc-etc which is same as limit of μ of A_n and that is what we wanted to prove okay, so let us stop with the corollary.

(Refer Slide Time: 11:35)

Cor: Suppose $A_n \downarrow A$. That is $A_1 \supseteq A_2 \supseteq A_3 \dots$
 then $A = \bigcap_{n=1}^{\infty} A_n$. If $\mu(A_1) < \infty$ then $\mu(A_n) \downarrow \mu(A)$

Pf: $A_1 \setminus A = \bigcup_{j=1}^{\infty} A_1 \setminus A_j$ (disj) $\bigcup \in \mathcal{F}$ $A_j \downarrow A$
 By the previous thm we have
 $\mu(A_1 \setminus A) = \mu(\bigcup_{j=1}^{\infty} A_1 \setminus A_j) \uparrow \mu(A_1 \setminus A)$
 $\mu(A_1) - \mu(A_2) \uparrow \mu(A_1) - \mu(A) \Rightarrow \mu(A_2) \downarrow \mu(A)$

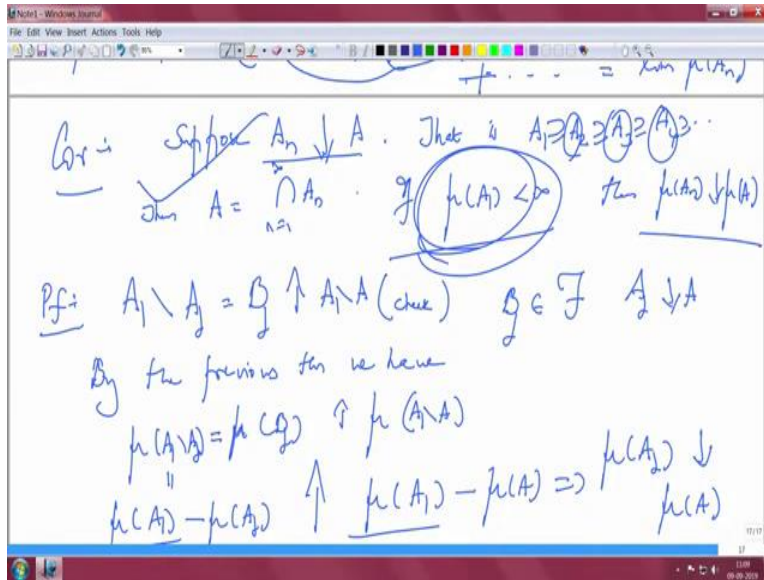

$\mu(\bigcup_{i=1}^n A_i) = \sum_{i=1}^n \mu(A_i)$ if A_j are disjoint

Theorem: 1) $\mu(\bigcup_{i=1}^{\infty} A_i) = \sum_{i=1}^{\infty} \mu(A_i)$ if A_j are disjoint

2) if $A \subseteq B$ $\mu(A) \leq \mu(B)$ / monotonicity $A, B \in \mathcal{F}$

3) if $A_1 \subseteq A_2 \subseteq A_3 \subseteq \dots$ $A = \bigcup_{i=1}^{\infty} A_i$
 then $\mu(A_n) \uparrow \mu(A)$ ($A_n \uparrow A$ $\mu(A_n) \uparrow \mu(A)$)

Pf: 1) A_1, A_2, \dots, A_n disjoint $A_{n+1}, A_{n+2}, \dots = \emptyset$

A similar proof corollary, suppose A_n are decreasing to A what does that mean? A_1, A_1 is the bigger set, A_2 is smaller than A_1 , A_3 is smaller than A_2 and so on, right it is decreasing, so what will be A ? Then A equal to intersection A_n right, n equal to 1 to n that is the limit of A_n okay. If μ of A_1 is finite so that is important then μ of A_n the limit is actually μ of A , so A_n decreases to A then μ of A_n decreases to μ of A .

So if we write this again, μ of A_n decreases to μ of A but you need the extra condition that μ of A_1 is finite otherwise it is not true okay, so let us prove this. So it is easy to deduce it from the earlier result, so A_i s are decreasing to you look at A_1 minus A_j , so let us call that B_j okay. So because that A_j is decreasing to A okay so A_1 minus A_j will increase to A_1 minus A okay, so check this, this is very easy.

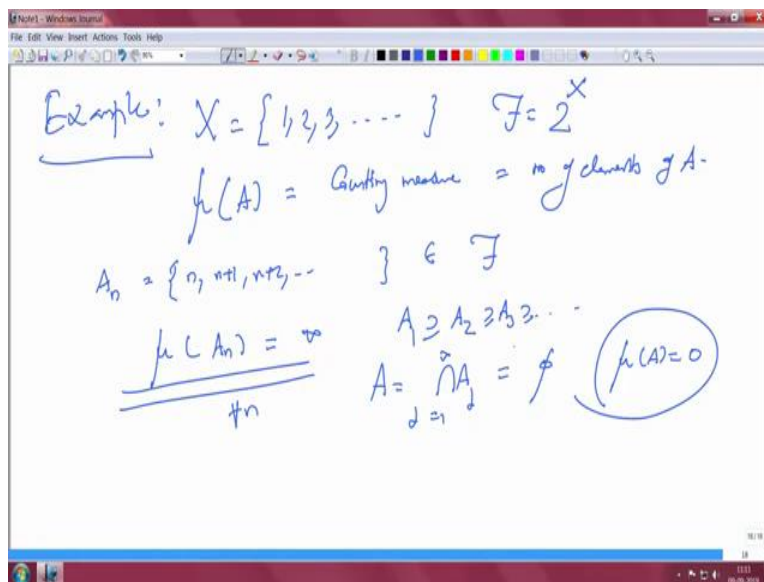

If I have a decreasing sequence of sets, if you look at compliments that will have to be increasing, right that is all we are using. So B_j is a collection of sets so remember B_j are also in the sigma algebra right because A_1, A_j they are all in the sigma algebra so B_j are also measurable j s, as it increases to A_1 minus A , so by the previous theorem we have μ of B_j increases to μ of the limit which is A_1 minus A , right.

Well what is μ of B_j ? So μ of B_j is μ of A_1 minus A_j which is equal to μ of A_1 minus μ of A_j because everything is finite remember that, so this is equal to μ of A_1 minus μ of A_j , A_j remember μ of A_1 is finite, so μ of A_1 is finite so μ of A_2 is finite, μ of A_3 is finite, μ of A_4 is finite etc everything is finite. This will converge to so well not converge it

actually increases to right by our previous result, μ of A_1 minus μ of A , okay which is same as saying, so μ of A_1 is common here and I am taking minus.

So this tells me that μ of A_j decreases to μ of A okay, so these two results are equivalent to a measure being countably infinite, so this property yeah this property and the corollary we have root later is actually equivalent to being countably additive. It is the property which characterizes the countable additive with us of the measure μ , but let us look at some example.

(Refer Slide Time: 15:36)

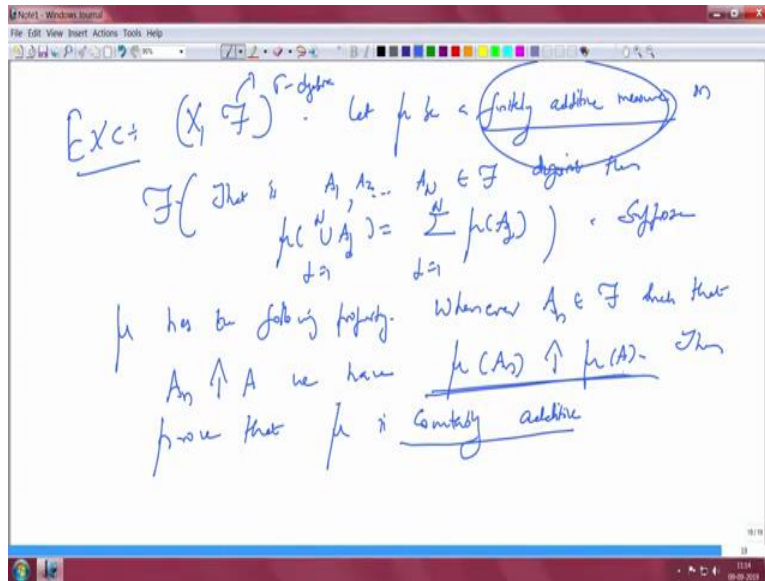

So one example to show why the extra condition in this is necessary? So we have this extra condition that μ of some set is finite that is necessary, why is that? So let us look at a simple example its 1, 2, 3 etc. so this is the integers, positive integers and the sigma algebra you take the our set all subset of x and define μ to be the counting measure, right, counting measure, so what is the counting measure?

So this is simply number of elements in A , so we know that it is a measure, okay, so let us define A_n , okay A_n is $n, n+1, n+2$ and so on. So that is a set right, so that belongs to script \mathcal{f} , right because script \mathcal{f} is all subsets, so this is a subset of x and sets. What is μ of A_n ? μ of A_n is the number of elements in A_n but that is infinity, there are infinitely many elements but A_n s are decreasing right, so A_1 has the whole space, A_2 is 2 onwards, A_3 is 3 onwards and so on.

So the limit is A which is the intersection A_j , j equal to 1 to infinity well what will be that? That is the empty set and μ of A is 0, okay. So I have μ of A_n to be infinite for every n and μ of A to be 0, so this does not converge to those okay, so the condition that one of the sets has finite measures is a necessary condition. So let me stop with an exercise.

(Refer Slide Time: 17:34)

Okay, so I have X and \mathcal{F} okay so this is sigma algebra let μ be a finitely additive measure on \mathcal{F} , what does that mean? That is if I take A_1, A_2 etc. A_n in a finitely many disjoint then μ of union A_j , j equal to 1 to n equal to summation μ of A_j , j equal to 1 to n . So this is what is called finitely additive, countable additive would be there are infinitely many sets disjoint and then you can add up.

So I start with a finitely additive measure, suppose μ have the following property, so this is the property which we just proved, whenever I have sets A_n in script \mathcal{F} such that A_n increases to A , so remember A_n increases to A meaning I have A_1 I have A_2 bigger than A_1 , A_3 bigger than A_2 and so on, right and A is the union of all sets.

Whenever this happens we have $\mu(A_n)$ increases to $\mu(A)$, okay then prove that μ is countably additive, so remember we started with a finitely additive measure and we are saying this property whatever we proved earlier assuming countable additivity now we can prove that the measure is countably additive assuming that it is only finitely additive but this extra property,

okay so that is what I meant by this properties more or less equivalent to being countably additive measure.

Okay so what we have done so far is to start with measurability of functions and we have looked at some property of the measure, in the next lecture we will start with integration of positive functions where we will use the symbol functions and then first define integral for symbol functions which would be immediate generalization of what we do for step functions in the case of Riemann integral and then we take we extend it to positive measurable functions and then to real valued and complex valued functions, that is what we will do, okay.
