**Product Measures II**

So, our aim in this lecture would be to define the product measures. So recall from the last lectures that we had two spaces  $X$  and  $Y$ . We looked at the product spaces  $X$  cross  $Y$ ,  $X$  and  $Y$  came with sigma algebras and we looked at the product sigma algebra  $\mathcal{F}$  cross  $\mathcal{G}$ , script  $\mathcal{F}$  cross script  $\mathcal{G}$ . And we have seen that it is the, it is a monotone class and it is the smallest monotone class containing the elementary sets. Our aim is to define a measure on script  $\mathcal{F}$  cross script  $\mathcal{G}$  using measures on  $X$  and  $Y$ , so now we will start with the measure space,  $X$  and  $Y$ , and then we will define a measure on  $X$  cross  $Y$ .

So, this has relevance to construction on  $\mathbb{R}^n$  as well. So, for example, if you look at  $\mathbb{R}^2$ ,  $\mathbb{R}^2$  can be viewed as  $\mathbb{R}$  cross  $\mathbb{R}$ . And then we have Lebesgue measure on the real line and you can ask, what is the product measure? Once we construct the product measure we will see that it is related to the Lebesgue measure on  $\mathbb{R}^2$ . In fact, it is same except for the Sigma algebra. So, those finer details will be explained later on. So, right now we will stick to the abstract settings,  $X$  and  $Y$ , we look at  $X$  cross  $Y$  and try to define a measure on  $X$  cross  $Y$ . Okay fine let us start.

(Refer Slide Time: 01:50)

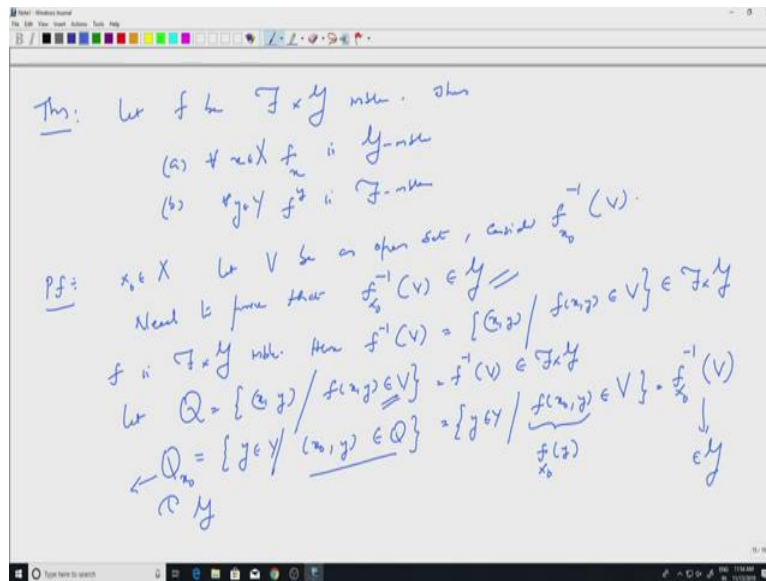

So, we have  $X$  we have  $F$  sigma algebra and we have  $Y$  and another simple algebra. So, before we go to measures, let us deal with measurable functions. So, I can have a function defined on  $F$ , defined on  $X$  cross  $Y$ , taking values in the real line or complex plane, etcetera, etcetera. And just like the sets, we can define, so, just like the sets, we can define the sections of these functions, sections of  $f$ . Well, how will I define this?

So, for  $x$  in  $X$ , define the  $x$  section of  $f$ , so  $f$  sub  $x$  this would be a function on  $Y$  to  $\mathbb{C}$  or  $\mathbb{R}$  or wherever it is or any other space. Well, how do you define this? You look at  $f$  sub  $x$  at  $y$  to be  $f$  of  $xy$ , so, this is the natural definition. Similarly, for  $y$  in  $Y$ , define the  $f$  super  $y$ , so this would be a function on  $X$ . So  $f_y$  at  $x$  is  $f$  of  $x$  comma  $y$  again. So, this is what we did for sets and we are extending it to, the sets will give you indicator functions and if you use indicator functions, you will see that they agree with the sections of the sets.

So, that is a trivial exercise which I will leave it to you. So, if I take a set then, if you look at indicator of  $E$  this is a function on  $X$  cross  $Y$ , so, I can look at its section sub  $x$  and you will see that this is the  $x$ , etcetera. So that is a trivial verification. So, that agrees with the indicator sections for indicator functions. Well so just like sets we should see how measurability is a vector.

(Refer Slide Time: 4:24)

So, let us write it as a easy theorem. So  $f$ , let  $f$  be  $F$  cross  $G$  measurable that means it is defined on  $X$  cross  $Y$  and it is measurable with respect to  $F$  cross  $G$ . So, if we take inverse image of any open set, I will land in the sigma algebra  $F$  cross  $G$ . So, then for every  $x$   $f$  sub  $x$  remember  $f$  sub  $x$  is a function defined on  $Y$ , so it is measurable with respect to  $G$ , is  $G$  measurable, and for every, so, every  $x$  in capital  $X$  similarly every  $y$  in capital  $Y$   $f$  super  $y$  is script  $F$  measurable, that is what one would expect.

So, looking at the cells for sets. So, let us take so let us fix an  $x_0$  in  $X$  so that it is clear what we are doing. We want to show that if  $f$  is measurable, then  $f$  sub  $x_0$  is  $G$  measurable. So, let  $V$  be an open set and consider  $f$  sub  $x_0$ , so I want to say this is measurable which means I look at the inverse image of an open set in the real line or complex plane, etcetera. And I want to where this is in  $G$ , so consider this.

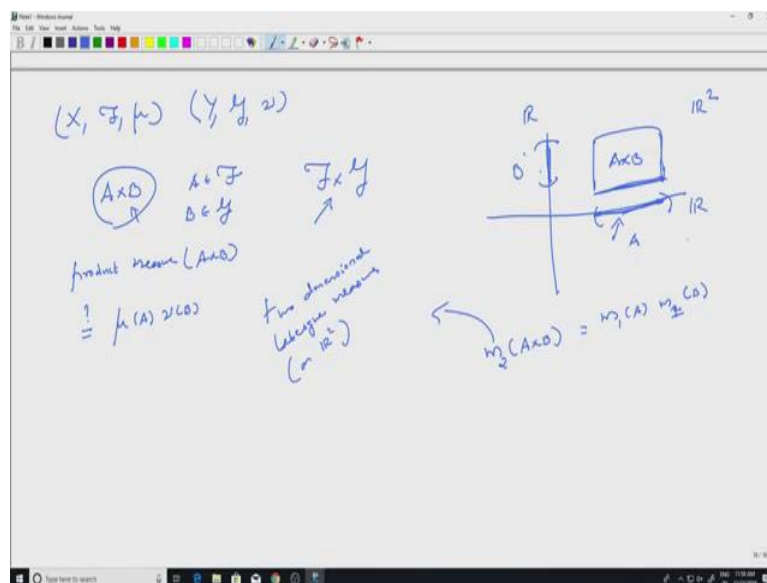

So, what do we need to prove? We need to prove that  $f$  sub  $x_0$ , my inverse of  $V$  this is actually in  $G$ , that is what we want show. Well,  $f$  is measurable, so  $f$  is script  $F$  cross script  $G$  measurable. Hence, if I look at  $f$  inverse of  $V$ , what is that? This is all those points in  $x$  cross  $y$  whose image under  $F$  belongs to  $V$ , that is a definition of  $f$  inverse of  $V$ . This of course is measurable, so this will belong to script  $F$  cross script  $G$ , because  $f$  is measurable.

Now, if I look at the, so let us call that  $Q$ . So, let  $Q$  equal to this set. So, this is the  $f$  inverse  $V$   $y$   $f$   $x$   $y$  in  $V$ . So, just a notation, so this is  $f$  inverse  $V$  and this belongs to the product sigma algebra, because  $f$  is measurable. So, now, let us look at the section of this, so  $Q$  sub  $x_0$ . So, what is  $Q$  sub  $x_0$ ? Well, this is all those  $y$  in  $Y$  such that  $x_0$  comma  $y$  belongs to  $Q$ , which is

same as all those  $y$  in  $Y$ . When is  $x_0$  comma  $y$  in  $Q$ ? Well that is same as saying  $f$  of  $x_0$  comma  $y$  is in  $Q$ .

Well, what is  $f$  of  $x_0$  comma  $y$ ? This is  $f$  sub  $x_0$  at  $y$  that is a definition. So, you are looking at all those  $y$  such that  $f$  sub  $x_0$   $y$  is in  $Q$ , which is same as  $f$  sub  $x_0$  inverse image of, sorry, not in  $Q$ , in  $V$ , this is the definition. So this is  $f$  sub  $x_0$  inverse of  $V$ . But  $Q$  is of  $x_0$ ,  $Q$  is a, this is a section of  $Q$  which is measurable and so, this will belong to script  $G$ . And so, this belongs to script  $G$  which is same as, that is what we want to prove, so measurability. So, this is an extremely trivial straightforward exercise, because sections are measurable, sections of measurable functions will be measurable that is trivial assertion.

(Refer Slide Time: 9:06)

So, now comes the main theorem, defining measure on the product space. So, before that, let us look at some trivial examples. So, let us look at, of course this does not define product measure, but this will sort of motivate what one should do. So let us look at  $\mathbb{R}^2$ . So, we have the Lebesgue measure on  $\mathbb{R}$  Lebesgue measure on  $\mathbb{R}$ , I want to look at the product sets. So, if I take a measure, an open interval like this here, let us call that  $A$ , and another interval here, let us say  $B$ , then  $A$  cross  $B$  is this open rectangle,  $A$  cross  $B$ .

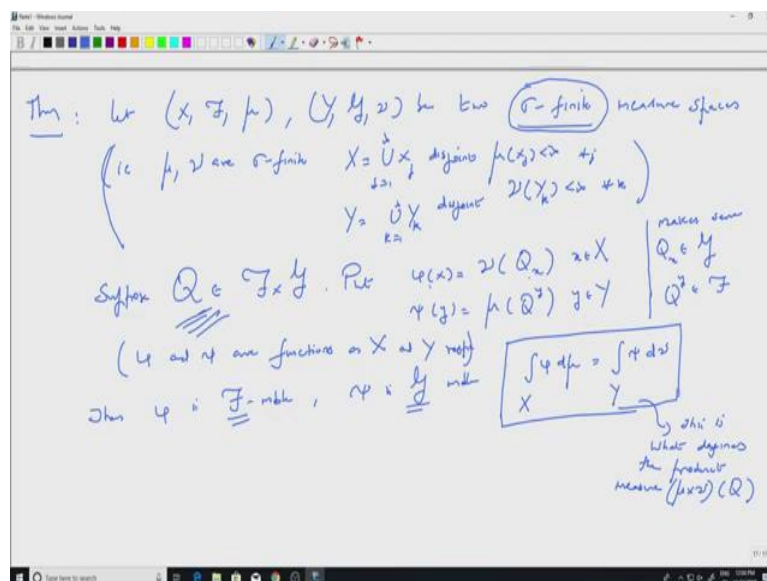

What is the measure of  $A$  cross  $B$ ? So, let us put  $m_2$  of  $A$  cross  $B$ . What is  $m_2$ ?  $m_2$  is the two-dimensional Lebesgue measure. So that is the Lebesgue measure on  $\mathbb{R}^2$  that is all. Because there are Lebesgue measures on  $\mathbb{R}$  and  $\mathbb{R}^2$ , so just to distinguish between them, I use  $m_2$ . So, what is this? This is the area of  $A$  cross  $B$ , which is the length of the rectangle times the breadth of the rectangle. But length of the rectangle is the length of this open interval and

that is (meas) one-dimensional Lebesgue measure of A. So, that is  $m_1$  of A times  $m_2$  of B sorry,  $m_1$  of B, the length here.

And so, this is, so this is what motivates the definition of the product measure. So if I have measurable rectangle, so, in general if I have let us say, X, F and  $\mu$  and I have Y, G and  $\nu$ , so two measures. If I take a measurable rectangle A cross B, A in script F, B in script G, then the product measure, whatever that means, we will define that product measure of A cross B should be the product of each of them, so that is  $\mu$  of A times  $\nu$  of B, this is what it should be.

Of course, the sigma algebra contains not just A Cross B's you have unions, complements and things like that of measurable rectangle, so there are very general sets here. So, we need to know how to (defi) extend this from measurable rectangles to all sets here, so that is the aim of the next theorem.

(Refer Slide Time: 11:59)

So, we will, so let us write on a new page. Theorem. So let X, F,  $\mu$  comma Y, G,  $\nu$  be two sigma finite measure spaces. Well, what does that mean? So, that is they are measure spaces, so both  $\mu$  and  $\nu$  are sigma finite, which means I can write X as union  $X_j$  j equal to 1 to infinity disjoint and measure of them is finite,  $\mu$  of  $X_j$  is finite. Similarly, I can write Y as union k equal to 1 to infinity,  $Y_k$  disjoint of course, disjoint union  $\nu$  of  $Y_k$  is finite for every k and for every j, this is what you mean by they are sigma finite measure spaces, disjointness follows because if they are not disjoint you can make them disjoint by looking at  $X_j$  plus 1 minus  $X_j$  and so on, we have seen this several times before.

Now, suppose so, aim is to extend the definition of the measure to  $F \times G$ . So, suppose I take a set in  $F \times G$ . So, remember  $F \times G$  is the smallest sigma algebra containing measurable rectangles, so this is a general set we are not looking at a measurable rectangle. Put  $\phi$  of  $X$  equal to  $\nu$  of  $Q$  sub  $x$ . Well, does this make sense? What is  $Q$ ?  $Q$  is in  $F \times G$ , so  $Q$  sub  $x$  is the section of  $Q$  will be in  $G$  and so  $\nu$  of that will make sense.

And similarly,  $\psi$  of  $Y$  to be  $\mu$  of  $Q$  super  $y$ , so this is for  $x$  in  $X$ ,  $y$  in  $Y$ . So, both of them makes sense, so makes. So, let me note it here, makes sense because  $Q$  sub  $x$  belongs to  $G$  and so, it is measurable and so  $\nu$  of that will make sense. Similarly,  $Q$  super  $y$  is in script  $F$  and so  $\mu$  is a measure on  $X$  this will makes  $\mu$  of  $Q$  super  $y$  makes sense, so that is important. So, these are functions, so  $\phi$  and  $\psi$  are functions on so.  $\phi$  and  $\psi$  are functions on  $X$  and  $Y$  respectively.

Well, what do we want to say? We want to say that then  $\phi$  is  $F$  measurable, because  $\phi$  is a function on  $X$  so, it is measurable with respect to the sigma algebra script  $F$  on  $X$  and  $\psi$  is measurable with respect to  $G$ . Moreover,  $\int \phi d\mu$ , this makes sense, because  $\phi$  is  $F$  measurable,  $\mu$  is a measure on  $X$  with on the sigma algebra and so, this is a well-defined integral. More than moreover these are all positive functions, because  $\nu$  of or  $\mu$  are positive measures, so their values are all positive, so both  $\phi$  and  $\psi$  are positive.

Well, this is same as  $\int \psi d\nu$ , because  $\psi$  is measurable with respect to script  $G$ ,  $\nu$  is a measure on script  $G$ , so the integral makes sense. These are positive function and they are equal. So that is the statement. So, this defines the product measure, I will comment on that later, but I hope the statement is clear, but let me repeat. So, I take 2 sigma finite measure space, so this is important, sigma finiteness is important otherwise, we run into some problems, we will see that in the proof.

When I take a measurable set in the product sigma algebra. I can look at the sections and define these functions  $\phi$  and  $\psi$ . So, the  $\phi$  and  $\psi$  are measurable accordingly so, in the sense that  $\phi$  is defined on  $X$  so it is measurable with respect to script  $F$  and  $\psi$  is measurable with respect to script  $G$  and these integrals are same. So, the integrals are same is the key. This is what defines, so this is what defines the product measure.

So, this we, we will define this to be the product of  $\mu$  with  $\nu$  So, this is a  $\nu$  measure and this would be the value at  $Q$ , because we started with this  $Q$  and we are saying some integrals are equal which should be the product measure. So, you can check if  $Q$  is a measurable

rectangle, it would give you exactly what you want, so that is our first step anyway. So, rest of this lecture would be to prove this theorem.

(Refer Slide Time: 18:11)

(i.e.  $\mu, \nu$  are  $\sigma$ -finite  $X = \bigcup_{i=1}^{\infty} X_i$  disjoint  $\mu(X_i) < \infty$   $\forall i$   
 $Y = \bigcup_{k=1}^{\infty} Y_k$  disjoint  $\nu(Y_k) < \infty$   $\forall k$ )

Suppose  $Q \in \mathcal{F}_X \times \mathcal{F}_Y$ . Put  $\nu_Q(x) = \nu(Q_x)$   $x \in X$   
 $\nu_Q(y) = \mu(Q^y)$   $y \in Y$

( $\nu_Q$  and  $\nu_Q$  are functions on  $X$  and  $Y$  resp)  
 Then  $\nu_Q$  is  $\mathcal{F}_X$ -measurable,  $\nu_Q$  is  $\mathcal{F}_Y$ -measurable

$\int \nu_Q d\mu = \int \nu_Q d\nu$   
 X Y

this is what defines the product measure  $(\mu \times \nu)(Q)$

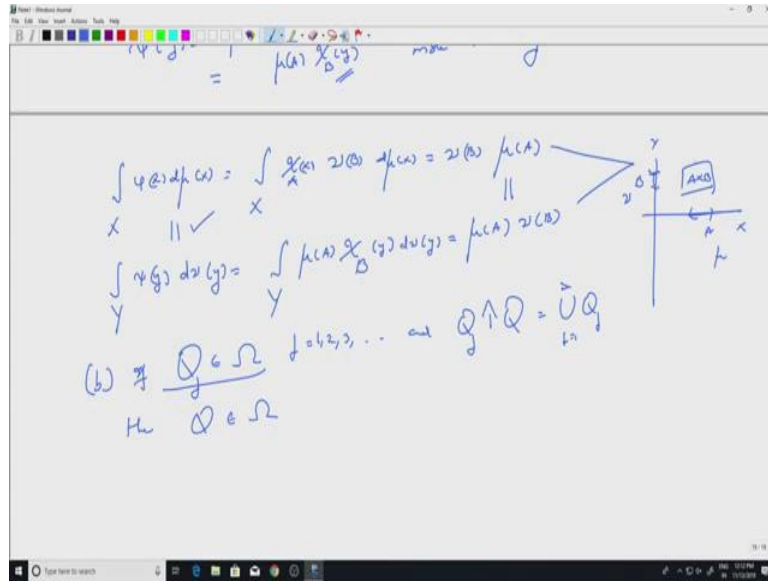

Pf let  $\Omega$  be the class of  $Q \in \mathcal{F}_X \times \mathcal{F}_Y$  for which the

Pf let  $\Omega$  be the class of  $Q \in \mathcal{F}_X \times \mathcal{F}_Y$  for which the  
 this is true

(a) measurable rectangles are in  $\Omega$   
 $Q = A \times B$   $Q_x = \begin{cases} B & x \in A \\ \emptyset & x \notin A \end{cases}$   $Q^y = \begin{cases} A & y \in B \\ \emptyset & y \notin B \end{cases}$

$\nu_Q(x) = \nu(Q_x) = \begin{cases} \nu(B) & x \in A \\ 0 & x \notin A \end{cases}$   
 $= \chi_A(x) \nu(B)$  — make w.r.t  $\mathcal{F}_X$

$\nu_Q(y) = \mu(Q^y) = \begin{cases} \mu(A) & y \in B \\ 0 & y \notin B \end{cases}$   
 $= \mu(A) \chi_B(y)$  — make w.r.t  $\mathcal{F}_Y$

So, theorem, the proof is not very difficult, but it is a very important itself because this is what defines the product measure on spaces, so proof. So, we start with, so let  $\omega$  be the class of sets  $Q$  in  $\mathcal{F} \times \mathcal{G}$ . So, you look at all those  $Q$  for which the theorem is true. So, the theorem has several assertions, so what are the, what does the theorem say? You define these functions  $\phi$  and  $\psi$  and then they are measurable and these integrals are same. So, there are two things one is measurability second is the integrals are same.

So, let us check. So, I take  $\omega$  to be the class of all such  $Q$  for which this is true. Of course we do not know if there is even one  $Q$  for which this is true, but our, we will justify all that. So, first thing is, as usual, measurable rectangles. So, measurable rectangles are in  $\omega$ , are in  $\omega$ , sorry  $\omega$ . Well, how do we prove this? So, let us take  $Q$  to be  $A \times B$ . I will not say the theorem assertion is true for  $A \times B$ .

Well, what do you have to do? You have to look at sections, evaluate their measures, see if they are measurable functions, and integrate them and see if the integrals are same. So, first look at measurable, first look at sections. So, what is  $Q_x$ ?  $Q_x$ , so we have seen this because it is a measurable rectangle,  $Q_x$  would be  $B$ , if  $x$  belongs to  $A$ , 0 otherwise. So, how do you write this? Well, this is same as. And let us also write  $Q^y$ . So,  $Q^y$  would be  $A$  if  $y$  belongs to  $B$  0 otherwise.

Because it is a measurable rectangle  $A \times B$ , so sections are very easy to compute. So, now  $Q_x$ , where does  $Q_x$  belong to? This belongs to  $\mathcal{G}$ , so this belongs to  $\mathcal{G}$ , this belongs to  $\mathcal{F}$ . So, what is  $\phi$  of  $x$ ? So,  $\phi$  of  $x$  by definition is you evaluate  $Q_x$ .

the measure of  $Q$  sub  $x$ , so that is  $\nu$  of  $Q$  sub  $x$ . Well, what is that? This is integral over  $x$ , so maybe I should be bit more careful here.

$\phi$  of sub  $x$  is  $\nu$  sub  $\nu$  of  $Qx$ . So, what is new of  $Qx$ ?  $\nu$  of  $Qx$  is  $\nu$  of  $B$ , if  $x$  is in  $A$  0 otherwise. Well so,  $Q$  sub  $x$ , so I am making some silly mistakes,  $Q$  sub  $x$  is  $\phi$  and  $Q$  super  $Y$  is also  $\phi$ , if it is not there, not 0 it is  $\phi$ . So, the measure of that is 0. So, this is the result you get. So, let us write this in a neater form, this is simply when  $x$  is in  $A$ , I have a constant, otherwise it is 0. So, this is simply indicator of  $A$  at  $x$  time that constant  $\nu$  of  $B$ .

So, as a function of  $x$  it is a constant times indicator function of a measurable function, so this is measurable with respect to script  $F$ . Similarly,  $\psi$  of  $y$ , well, this is  $\mu$  of  $Q$  super  $y$ , again you can write this in this form, so,  $Q$  super  $y$  is given here, so that is  $\mu$  of  $A$  if  $y$  is in  $B$  0 otherwise, which we write in a neater form to be  $\mu$  of  $A$ , which is a constant times indicator of  $B$  at  $y$ . On  $B$  it is a constant, so  $\mu$  of  $A$ . So, you will simply multiply indicator of  $B$  with a constant and so it is measurable, because this is a indicator of a measurable function, so this is measurable with respect to script  $G$ . So, that is the first assertion. So, we started with a measurable rectangle and we proved that  $\phi$  and  $\psi$  are measurable.

Now, we have to prove that integrals are same, so let us look at, so that should give you what you want. So, integral over  $x$   $\phi(x) d\nu(x)$ , what is this? This is integral over  $x$ ,  $\phi$  I know is indicator of  $A$  times  $\nu$  of  $B$ , which is a constant. So, let me put the  $x$  here, so that we understand what is the function and so on. So, this is equal to  $\nu$  of  $B$  is a constant that comes out,  $\nu$  of  $B$ . And what remains is integral of the indicator, which is the measure of that set  $\mu$  of  $A$ .

And let us look at the other integral  $\psi(y) d\mu(y)$ ,  $d\nu(y)$  because our measure is  $\nu$  there,  $d\nu$  of  $y$  this is integral over  $y$ .  $\psi(y)$  we have written it in a neater form, this is this  $\mu$  of  $A$ , which is a constant times indicator of  $B$  characteristic function of  $V$ , this is equal to  $\mu$  of  $A$  is a constant that comes out,  $\mu$  of  $A$ . And then you are integrating the indicator characteristic function of  $B$ , so you will get the measure of  $B$ , but these two are same, so these two integrals are same. And that is all we needed to prove.

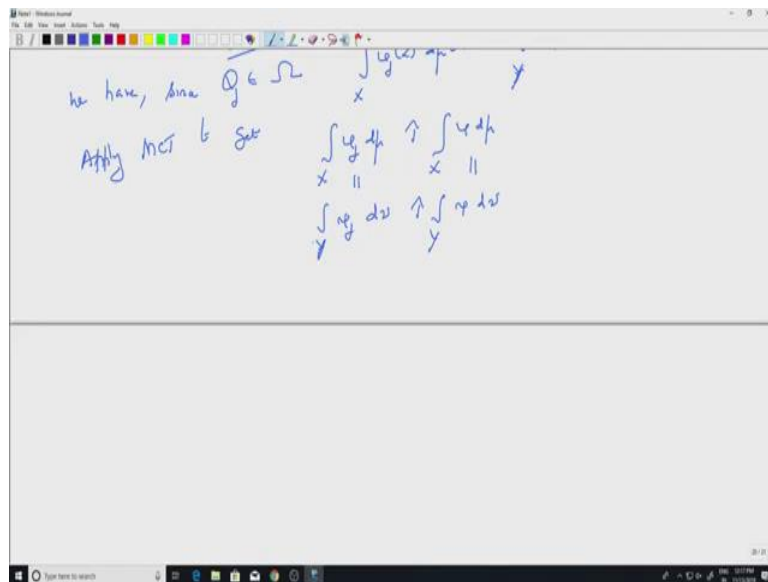

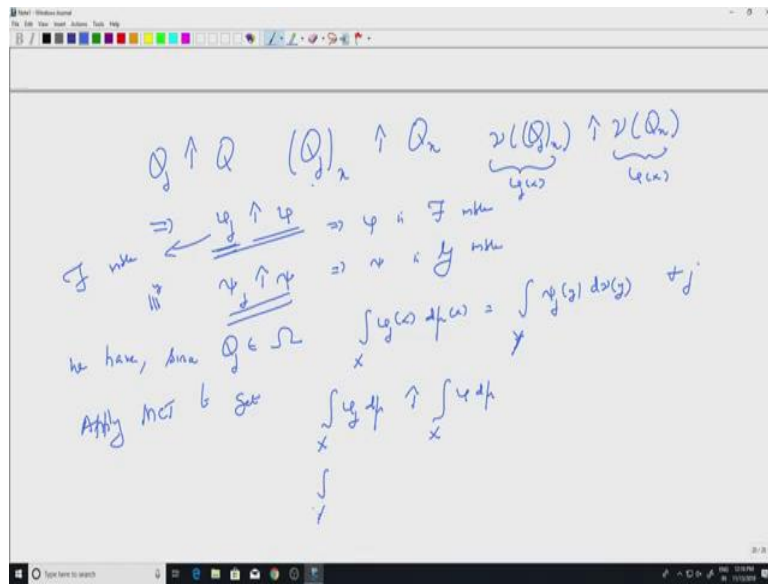

So, we needed to prove this assertion and these two assertions. So, both are same when, when the set  $Q$  is a measurable rectangle. So, whenever you have measurable rectangles you have the theorem to be true. Now, let me come. So, look at these expressions, this is what you want. So, you have  $x$  here, you have  $y$  here and you have some set  $A$  here, you have some set

B here and you have the measure mu here, you have the measure nu here. So, the measure of A cross B the product measure of A cross B should be measure of this times measure of this that is what we have done. But this is only for measurable rectangles.

So, next step, so that is step B. So, if  $Q_j$  are in  $\omega$ . So, remember  $\omega$  is the collection of sets for which the theorem is true.  $j$  equal to 1, 2, 3, etcetera. And  $Q_j$  increase to  $Q$  of course  $Q$  has to be union  $Q_j$  then  $j$  equal to 1 to infinity and  $Q$  well then to conclusion, then so, I started with  $Q_j$  in  $\omega$  then I want to say  $Q$  is also in  $\omega$ . So, I am trying to prove that  $\omega$  is a monotone class, so increasing limits are there and I want to say decreasing limits are there,  $\omega$  is a monotone class and I will prove that  $\omega$  contains elementary sets and so  $\omega$  will contain all sets from the product sigma algebra by the monotone class theorem.

(Refer Slide Time: 26:49)

$\int \nu(g) d\nu(y) = \int \mu(A) d\nu(y)$   
 $Y$   
 $(b) \nexists Q_j \in \Omega$   
 $H_w \underline{Q} \in \Omega$   
 $let \nu_j(x) = \nu((Q_j)_x)$   
 $\nu(x) = \nu(Q)$   
 $\nu_j(y) = \mu(Q_j^c)$   
 $\nu(y) = \mu(Q^c)$   
 $Q_j \uparrow Q \quad (Q_j)_x \uparrow Q_x \quad \underbrace{\nu(Q_j)_x}_{\nu_j(x)} \uparrow \underbrace{\nu(Q_x)}_{\nu(x)}$   
 $\Rightarrow \nu_j \uparrow \nu \Rightarrow \nu \text{ is } \mathbb{F} \text{ mkr}$

So, define, so first we prove that  $\omega$  is closed under increasing limit. So, let  $\phi_j$  of  $x$  to be  $\mu$  of  $Q_j$  sub  $x$ , so I am just denoting the corresponding functions by  $\phi_j$  and  $\psi_j$  and  $\psi_j$  of  $y$  to be  $\nu$  of  $Q_j$  super  $y$ . And of course,  $\phi_j$  I will write it as  $\mu$  of  $Q$ , remember  $Q$  is the union of  $Q_j$ 's,  $\psi_j$  is the corresponding function for  $Q$  super  $y$ . What do we know?  $Q_j$  are increasing.

So, let us look at the definition. So,  $Q_j$  increases to  $Q$ , so then  $Q_j$  sub  $x$  the section will increase to the corresponding section  $Q$  sub  $x$ . So, if I look at  $\mu$  of  $Q_j$  sub  $x$ , that will of course increase to  $\mu$  of  $Q$  sub  $x$ , by property of the measure,  $Q$  we have an increasing limit and so, the corresponding thing will happen for the measure. So, that is same as saying  $\phi_j$ , because this is my  $\phi_j$  at  $x$ , so  $\phi_j$  increases to  $\phi$ , this is my  $\phi$  at  $x$ .

But what do I know about  $\phi_j$ ? They are coming from  $Q_j$ 's, but the  $Q_j$ 's are in  $\omega$ , which means  $\phi_j$  are measurable, so,  $\phi_j$  are defined on  $X$  and so, they are  $\mathcal{F}$  measurable. And  $\phi$  is a limit of measurable functions, so this implies  $\phi$  is  $\mathcal{F}$  measurable. Similarly, for  $\psi_j$  will increase to  $\psi$  implies  $\psi$  is  $\mathcal{G}$  measurable. So, good, we are in a good shape now.

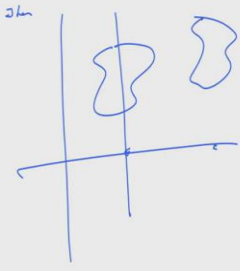

Now we look at, so measurability is done now we have to prove that the integrals are same. What do we know? We know that the integrals for  $\phi_j$  and  $\psi_j$  are same. We have since,  $Q_j$  belong to  $\omega$ ,  $\omega$  is where the theorem is true, so if  $Q_j$  belong to  $\omega$  then the integrals for  $Q_j$  are same, which is same as saying  $\int_X \phi_j d\mu = \int_Y \psi_j d\nu$ , this is true for every  $j$  that is given to us, we want to do the same for  $\phi$  and  $\psi$ , which are the functions related to  $Q$ .

Well, what do we do? We use this,  $\phi_j$  I know increases to  $\phi$ ,  $\psi_j$  increases to  $\psi$ , so what can you apply? You are looking at integrals, so apply monotone convergence theorem, apply modern convergence theorem to get  $\int_X \phi_j d\mu$ , I know that that will increase to  $\int_X \phi d\mu$ . And  $\int_Y \psi_j d\nu$  will of course  $\int_Y \psi d\nu$ , because we are on the other space,  $\int_Y \psi_j d\nu$  will of course, increase to  $\int_Y \psi d\nu$  by monotone convergence theorem.

But these two are equal because  $\phi_j$  and  $\psi_j$  are coming from  $Q_j$  for which the theorem is true. So, these two will be equal. So, that is all we needed to prove. So, what did we prove? If I have  $Q_j$ 's in  $\omega$  and  $Q_j$  increases to  $Q$ , then  $Q$  is also in  $\omega$ , so  $\omega$  is closed under increasing limits.

(Refer Slide Time: 31:13)

 $Q = \bigcup_{j=1}^{\infty} Q_j \in \Omega$   
 $\Rightarrow F = Q_1 \cup Q_2$  disjoint  $\left\{ \begin{array}{l} Q_1 \in \Omega \\ Q_2 \in \Omega \end{array} \right.$   
 $F_2 = (Q_1)_2 \cup (Q_2)_2$  disjoint

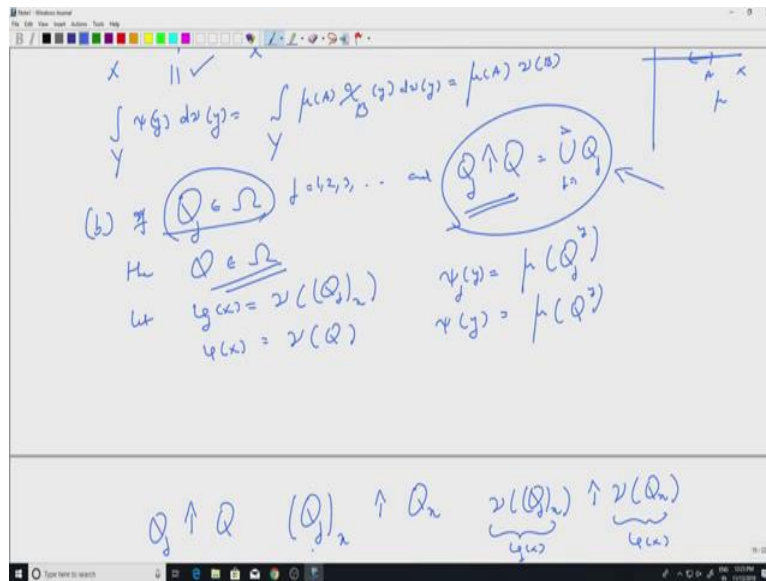

$(c)$  let  $Q_j \in \Omega$   $j=1,2,3,\dots$  disjoint  $\Rightarrow$   
 $Q = \bigcup_{j=1}^{\infty} Q_j \in \Omega$   
 $\Rightarrow F = Q_1 \cup Q_2$  disjoint  $\left\{ \begin{array}{l} Q_1 \in \Omega \\ Q_2 \in \Omega \end{array} \right.$   
 $F_2 = (Q_1)_2 \cup (Q_2)_2$  disjoint

$\mu(F)$   
 $\mu(F_2) = \mu((Q_1)_2) + \mu((Q_2)_2)$   
 $\mu(x) = \mu_1(x) + \mu_2(x)$   
 $\mu(y) = \mu_1(y) + \mu_2(y)$

$\int \mu(x) \mu(y) = \int \mu_1(x) \mu_2(x) + \int \mu_2(x) \mu_1(x)$   
 $= \int \mu_1(x) \mu_2(x) + \int \mu_2(x) \mu_1(x)$   
 $= \int \mu(x) \mu(y)$

$\mu(x) = \mu_1(x) + \mu_2(x)$   
 $\mu(y) = \mu_1(y) + \mu_2(y)$

$(disjoint) Q \cup Q_2 \dots \cup Q_n \in \Omega$   $Q_j \in \Omega$   
 $Q = \bigcup_{j=1}^{\infty} Q_j = \text{increasing limit of } \bigcup_{k=1}^n Q_k = A_n \uparrow Q$   
 $\in \Omega$   
 $Q \in \Omega$  by the finiteness prop.

So, next one, c. Let  $Q_j$  be in  $\Omega$ ,  $j$  equal to 1, 2, 3, we have not proved decreasing limits, we have only proved for increasing limits, but this is a slightly different one, because we need to prove that elementary sets are there, so we look at  $Q_j$  in  $\Omega$ , we take them to be disjoint then  $Q$  equal to union  $Q_j$   $j$  equal to 1 to infinity also in  $\Omega$ . Remember they are only disjoint they, so there is no increasing limit here we will you can convert it into an increasing limit. Well, let us do that first.

So, first take two sets. Suppose,  $F$  equal to, I will use a different letter,  $F$  equal to  $Q_1$  union  $Q_2$ . I know that  $Q_1$  and  $Q_2$  are in  $\Omega$ , which means the theorem is true for them, correct? Now, if I look at  $F$  sub  $x$ , what is this? This is  $Q_1$  sub  $x$ , so you can check this things  $Q_2$  sub  $x$ . So, we have done this before, so sections of  $F$  are sections of  $Q_1$  and  $Q_2$  put together but this is a disjoint union and so the sections are also disjoint that is very easy to see if you look at some set like this and some other set like this, the sections are going to be disjoint.

So, this section and this sections are disjoint. Well, we will have to check that, so it is not difficult, but. So, because of this, the measures will add up, so, these are function, these are subsets of script  $\mathcal{G}$ . So, if I look at  $F$  sub  $x$ , then because they are disjoint, so I will get  $Q_1$  sub  $x$  plus  $\nu$  of  $Q_2$  sub  $x$ , correct? Because they are disjoint. What did we prove? So remember, this is our  $\phi$ , so  $\phi$  of  $x$  equal to this is  $\phi_1$  of  $x$  plus  $\phi_2$  of  $x$ .

Similarly, if I look at  $\psi$  of  $y$ , so, what is  $\psi$ ?  $\psi$  is the corresponding function, so that would be  $\mu$  of  $F$  super  $y$ . So, this would be  $\psi_1$  of  $x$  plus  $\psi_2$  of  $x$  and we are trying to prove that certain integrals are same, but that follows immediately now, because we know that this is true for  $\phi_1$  and  $\phi_2$ . So, if we look at integral over  $x$   $\phi$   $x$   $d\mu$   $x$  so, by linearity, it

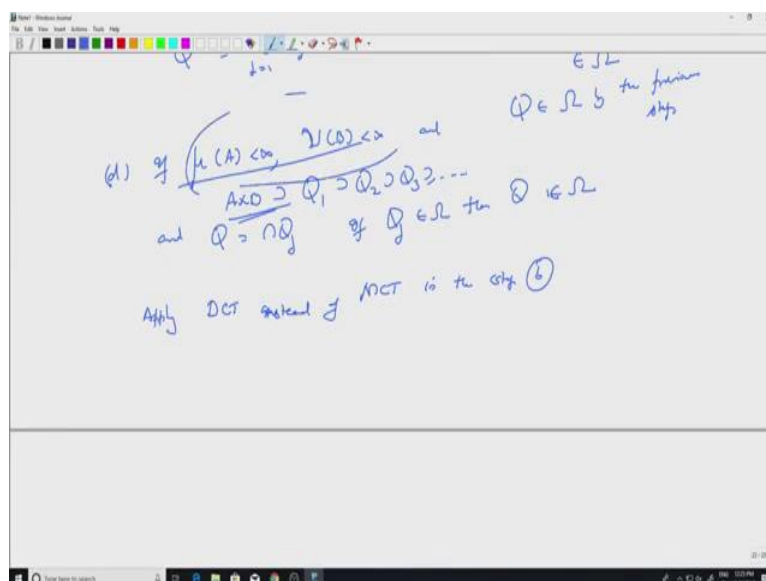

becomes sum of two things  $\int \phi_1(x) d\mu(x) + \int \phi_2(x) d\mu(x)$ , which is equal to, because  $\phi_1$  and  $\phi_2$  have the same property, because they come from  $Q_1$  and  $Q_2$ , which are in  $\Omega$  for which the theorem is true.

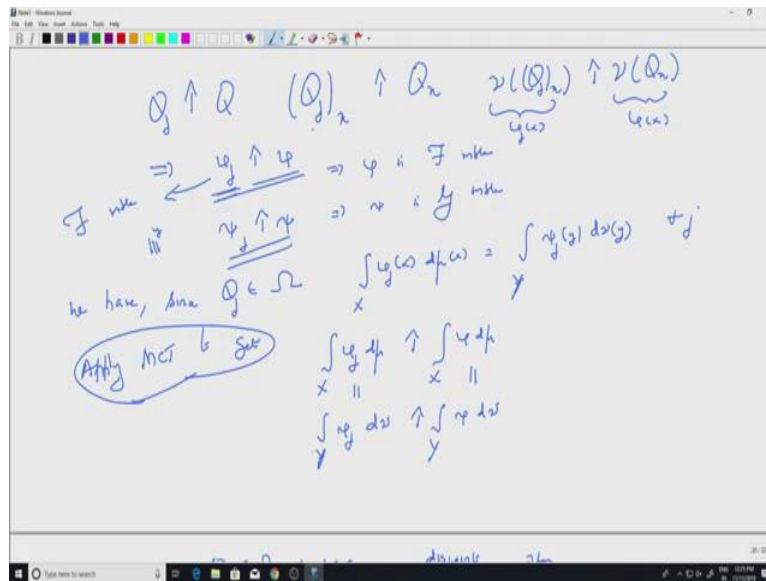

So, this becomes  $\int \psi_1(x) d\nu(x) + \int \psi_2(x) d\nu(x)$ , which by linearity becomes  $\int (\psi_1 + \psi_2)(x) d\nu(x)$ , which is  $\int \psi(x) d\nu(x)$ . So, this is equal to this, which is the integral in equality. So, measurability sorry measurability follows that I should have mentioned,  $\phi_1$  is measurable,  $\phi_2$  is measurable, so these are  $\mathcal{F}$  measurable, and so, sum is measurable, similarly, for these two.

So, if I have disjoint union of two such sets, then I have, I know that that is in  $\Omega$ . So hence. So, now we go back to our situation. So, I have  $Q_1, Q_2, \dots, Q_n$  will be in  $\Omega$ , if so, this is a disjoint union, they will be in  $\Omega$  if  $Q_j$  are in  $\Omega$ . But then  $Q = \bigcup_{j=1}^{\infty} Q_j$  is the increasing limit of  $Q_k = \bigcup_{j=1}^k Q_j$ , you go up to  $n$ , then next one is  $n+1$  and you are adding that, you are taking the union of that set, so that is an increasing limit.

So, you can call those  $A_n$  if you want, so then  $A_n$  increases to  $Q$ . But each of them, so they are all in  $\Omega$  and  $\Omega$  is closed under increasing limit by B. So,  $Q$  will be in  $\Omega$  by the previous by the previous step. So let us go back, what did we wanted to prove? We want to prove that if I have disjoint sets, then union will be in  $\Omega$ . And we use the fact that it is closed under increasing limits, this is the fact that it is closed under increasing limits.

(Refer Slide Time: 37:42)

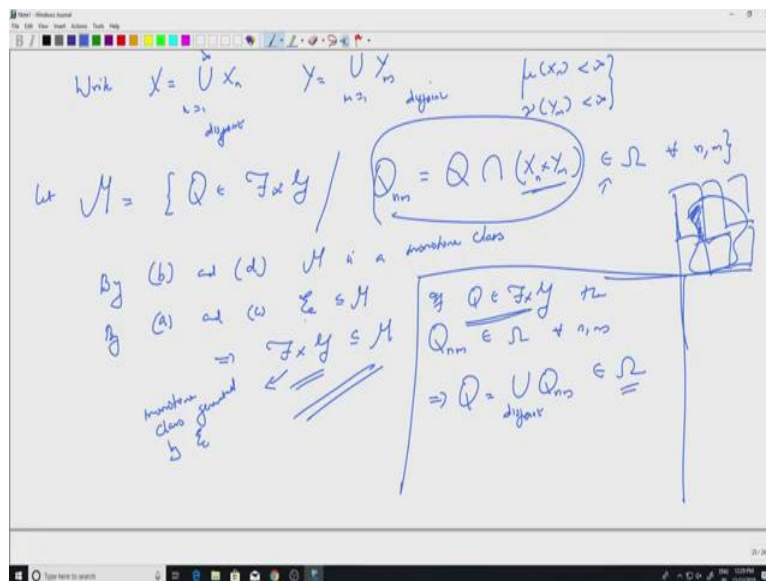

So, we have proved three properties a, b, c, we need one more, one more property, so let us call that d. So, if so I will be brief here, it because it is the same kind of arguments.  $\mu(A) < \infty$ ,  $\mu(B) < \infty$  and  $A \times B$  contains  $Q_1$  containing  $Q_2$  containing  $Q_3$ . We are now trying to prove that decreasing limits are also there and let us say  $Q = \bigcap Q_j$  if  $Q_j$  are in  $\Omega$  then  $Q$  is in  $\Omega$ . So, that means if  $Q_j$ 's are decreasing and  $Q_j$  for  $Q_j$  theorem is true then  $Q$  is also, for  $Q$  also the theorem is true provided you have this condition.

So, it is not very difficult to see, because earlier we used monotone convergence theorem, now, we want to look at something which is decreasing, so, that finite condition will apply. So write, so apply DCT instead of instead of monotone convergence theorem in the step b. There we had increasing limits, so let me go back and just show you that here we had increasing limit and then we used monotone convergence theorem.

Here we will have decreasing but then for integrals to decrease and then limits to exist and interchange integrals you need you need a dominating function and the dominating function is provided by indicator of  $A \times B$  and that has measure finite that is the point. So, I will leave that part to you that is an easy exercise.

(Refer Slide Time: 39:51)

So, now, we can conclude the (proper) prove that omega is a monotone class. So, write X equal to union  $X_n$   $n$  equal to 1 to infinity  $Y$  equal to union  $Y_m$   $m$  equal to 1 to infinity. So, all those are disjoint, disjoint and  $\mu$  of  $X_n$  is finite, because it is sigma finite, so we have this property and  $\nu$  of  $Y_m$  is finite. So, we want to prove that for every set in the product sigma algebra, the theorem is true.

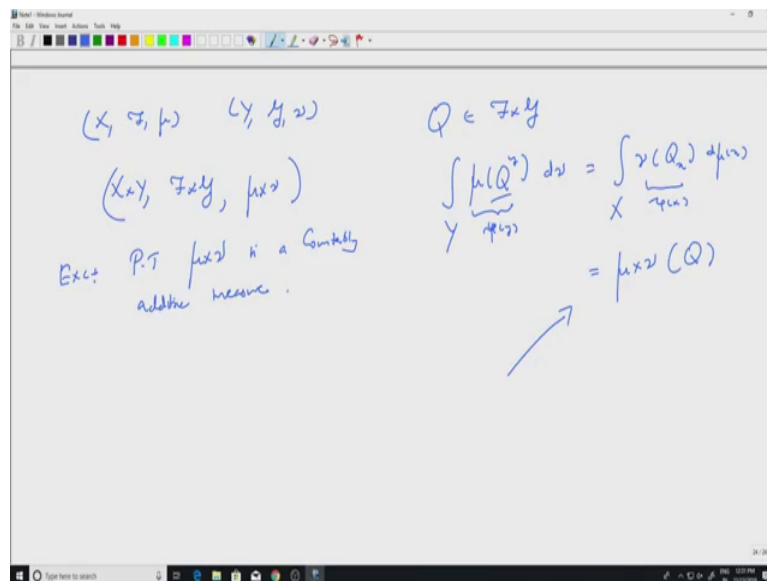

So, for that we consider this set, let script M to be equal to Q in F cross G, such that  $Q_{nm}$  so, what is  $Q_{nm}$ ? So, this is Q intersected with  $X_n$  cross  $Y_m$ . So this is in omega for every n and m. So X cross Y is sort of converted into rectangles  $X_n$  cross  $Y_m$ . So, and I am intersecting. So, if I take a Q like this, I am intersecting it with each of these rectangles, so this will be one such piece  $Q_{nm}$ . And I want to say, if  $Q_{nm}$  is in omega, for every n and m you look at all such Q's put together.

So, by the property b and d, m is a monotone class, it is closed under monotone limits. The property d is applicable because of this, because these are finite. So, this is like A cross B, where A and B have finite measure. So, by a and c, property seem elementary sets are inside M, but M is a monotone class, elementary sets are inside M, so the monotone class generated by elementary sets will also be in M.

So, this implies that F cross G itself, because this is the monotone class generated by script T that is the monotone class theorem. So, that will also be in M, which means that for every set in F cross G, we have these  $Q_{nm}$ 's for which the theorem is true, then you can put together. So, let last line, maybe I will write it here.

So, if I take  $Q$  in  $\mathcal{F} \times \mathcal{G}$  then  $Q_{nm}$  belongs to  $\Omega$  for every  $n$  and  $m$ , because of this, this is what we have just proved. So implies, this implies that  $Q$  equal to union  $Q_{nm}$ , remember this is a countable disjoint union, will also belong to  $\Omega$ , and that is all we wanted to prove. So, whatever set you take in  $\mathcal{F} \times \mathcal{G}$  that will be in  $\Omega$  which means that the, so, let me write down this as a separate statement

(Refer Slide Time: 43:38)

You have  $X$ , you have  $\mathcal{F}$ , you have  $\mu$  and similar measure space  $G$  and  $\nu$ , you have  $X$  cross  $Y$  now, you have  $\mathcal{F}$  cross  $\mathcal{G}$  now and I am looking at the measure. So, I take any  $Q$  in  $\mathcal{F}$  cross  $\mathcal{G}$ , what did we prove? We proved that if I take  $\mu$  of  $Q$  super  $y$  and integrate with respect to  $y$   $d\nu$ , I know that this is same as integral over  $x$   $\nu$  of  $Q$  sub  $x$   $d\mu_x$ , this is what we prove, these two integrals are same, this is the function  $\phi$   $y$  and this is the function, sorry, this is the function  $\psi$   $y$  and this is the function  $\phi$   $x$ , these integrals are same as  $(\mu \times \nu)(Q)$  (44:33).

So, this will define to be  $\lambda$  cross, sorry, not  $\lambda$   $\mu$  cross  $\nu$  of  $Q$ . So, the measure we have is  $\mu$  cross  $\nu$ , how is it defined? This is the definition. So, exercises trivial, prove that this is a measure, prove that  $\mu$  cross  $\nu$  is a countably additive measure but that we have already done if I take  $Q_j$ 's to be disjoint, I know the sections are disjoint, so this will add up, this will add up and then integrals will be same, because of monotone convergence theorem. But I will probably indicate the proof in the next lecture.

So, let us stop here. What we have done is to define a measure on the product space using the measure on each component. So in particular, if you have a measure on  $X$  and a measure on  $Y$ , then you have a measure on  $X$  cross  $Y$  related to the measures on  $X$  and  $Y$ , and it gives the

value for a measurable rectangle like  $A \times B$ , the natural one which is the measure of  $A$  times the measure of  $B$ . And this, of course, will have some relevance in the case of Lebesgue measure on  $\mathbb{R}^2$  or product spaces like  $\mathbb{R}^n \times \mathbb{R}^m$ . We will see the relation of those things in the next few lectures. So, we will stop here.
