Lecture 45

Applications of Fubini's theorem

We will start with some Applications of Fubini's Theorem, it will also give you some examples of functions, which are in L^1 . So, that you get the familiarized with this spaces. We saw some of this earlier, we will see how Fubini's theorem and the polar coordinates help in deciding certain functions are in L^1 and then we will see the convolution on L^1 , that also will be an application of Fubini's theorem. So, let us start with recalling the polar coordinates.

(Refer Slide Time: 01:04)

So, recall that, recall polar coordinates on \mathbb{R}^n . So, well, so strictly speaking it is \mathbb{R}^n minus a point 0, we identify this with $(0, \infty) \times S^{n-1}$, and we had two spaces, the Lebesgue sigma algebra of $(0, \infty)$ and r to the $n-1$ dr. So, that was our measure, so one such, the other space was S^{n-1} and we had a sigma algebra \mathcal{G} and a measure σ .

So, what is σ ? σ was the measure defined by, if I take a set E , this was n times the Lebesgue measure of \tilde{E} , where \tilde{E} was the sector. So, \tilde{E} is the sector defined by sector defined by E . So, let me recall that, this is simply all those points $\rho\omega$, where ρ was between 0 and ∞ and ω was in E . E remember is a subset of S^{n-1} .

So, in some, some points on the unit sphere, you sought of draw the lines from those points to the origin, write in do not include the origin. So, that is your sector and you look at a Lebesgue measure of that. So, that is you sigma. So, this give such the polar coordinates. So, if f is suitable function, we have integral over \mathbb{R}^n , $f \, d\mu$ equal to integral over 0 infinity integral over S^{n-1} $f(r\omega) r^{n-1} d\mu(\omega) dr$.

So, that is the inner integral, $\int_{S^{n-1}} f(r\omega) d\mu(\omega)$. Of course if f is positive you can interchange the integrals sought of a f s in L^1 you can interchange the integral etc. So, such things will be used in computations. But let us look at, let us use this in some examples, examples. So, consider the function, consider the function, so this is defined on \mathbb{R}^n , let us takes values in the real line. It is actually positive.

So, f of x is going to be defined by $1/(1+|x|^2)^{(n+1)/2}$. So, n is the dimension. So, $|x|$ is the usual norm of X, $|x|$ is modulus of x_1, x_2, \dots, x_n , this is summation x_j^2 , j equal to 1 to n to the half, usual definitions. I want to say, so we want to, we want to prove or check, we want to check, if f is in L^1 , of course this is a continuous function, so it is a measurable, so this is continuous, so measurable. So, such things do not cause any problem, measurability, question is, it is integral or not? So, I want to compute the integral of f and see if it is finite.

(Refer Slide Time: 04:54)

The whiteboard contains the following handwritten mathematical derivation:

$$\int_{\mathbb{R}^n} f \, d\mu = \int_0^\infty \left(\int_{S^{n-1}} f(r\omega) \, d\mu(\omega) \right) r^{n-1} \, dr$$

$\int_{S^{n-1}} \frac{1}{(1+r^2)^{(n+1)/2}} \, d\mu(\omega) = \int_{S^{n-1}} \frac{1}{(1+r^2)^{(n+1)/2}} \, d\mu(\omega)$ (independent of ω)
 $\int_{S^{n-1}} d\mu(\omega) = n \pi^{n/2} (radius)^{n-1}$
 $= n \pi^{n/2}$ (unit ball)

$$= \int_0^\infty \frac{1}{(1+r^2)^{(n+1)/2}} \, dr$$

f is a radial function

So, we look at integral over \mathbb{R}^n , one should take mod f but f is positive. So, $\int f \, d\mu$, this is what we want to compute, which is of course by polar coordinates, it is $\int_0^\infty \int_{S^{n-1}} f(r\omega) \, d\sigma(\omega) \, r^{n-1} \, dr$. But f of $r\omega$, so what is f of $r\omega$? So, ω is a point in S^{n-1} , r is a positive number.

So, this is well, the definition of f tells me that this is $1 + r^n$. But $\int_{S^{n-1}} d\sigma(\omega)$ is equal to 1 , because ω is in the unit sphere. So, this is simply $\int_0^\infty (1 + r^n) r^{n-1} \, dr$. So, modulus of r is that $n + 1$. So, this, this is independent of ω , independent of ω such functions are called radial function. So, this is same as saying f is a radial function, radial means it dependence only on the distance from the origin.

So, radial function, so such functions do not depend on ω , they depend only on $\|x\|$, that is R . So, this I can write as, so here there is no dependence on Ω . So, I have simply integral over $S^{n-1} \, d\sigma$. So, that is some constant, times integral $\int_0^\infty (1 + r^n) r^{n-1} \, dr$. So, the constant comes out.

So, this is a finite constant, finite constant, well why is that, so because this is a measure of the whole space. What is S^{n-1} , by definition? So, this is n times the sector defined by S^{n-1} . So, you look at S^{n-1} , look at its sector. So, what does the sector define by S^{n-1} ? That will be the whole unit ball. So, n times unit ball, but unit ball has measure finite, it is compact set. So, it is a bounded set, so it has finite measure. So, this is strictly finite you can actually computed I will tell you how to do that.

(Refer Slide Time: 07:22)

The image shows a whiteboard with handwritten mathematical notes. At the top, there is an equation:
$$= \int_0^{\infty} \frac{1}{(1+r)^{n+1}} r^{n-1} dr = \int_0^1 \frac{1}{(1+r)^{n+1}} r^{n-1} dr + \int_1^{\infty} \frac{1}{(1+r)^{n+1}} r^{n-1} dr$$
 The first integral is labeled "independent" and the second is labeled "radial function". Below this, there are notes: $\int_0^1 \frac{1}{(1+r)^{n+1}} r^{n-1} dr = \int_0^1 \frac{1}{(1+r)^{n+1}} r^{n-1} dr$ and $\int_1^{\infty} \frac{1}{(1+r)^{n+1}} r^{n-1} dr \leq \int_1^{\infty} \frac{1}{r^{n+1}} r^{n-1} dr = \int_1^{\infty} \frac{1}{r^2} dr$. There are also notes about "independent" and "radial function".

So, right now we need only that it is a finite constant. Now, so we need to look at only this quantity. So, let us look at that separately integrals 0 to infinity, 1 by 1 plus r to the n plus 1, r to the n minus 1 dr. Well the integrand in r is a continuous function. So, this is a continuous function in r. So, it will be finite over any compact set.

So, we need to look at only what happens at the infinitive. So, this I can write as integral let us say 0 to 1 plus 1 to infinity, these are all Lebesgue integrals by the way. We are decomposing the domain of integration into two sets. So, that is all we have done, this plot is finite because I am integrating a continuous function over a compact set. I need look at only this part. So, this is less than or equal to, well I will write it as 1 to infinity, 1 by 1 plus r. So, 1 by 1 plus r is of course less than or equal to 1 by r and I have n plus 1. So, I have 1 by r to the n plus 1 and I have r to the n minus 1 dr.

(Refer Slide Time: 8:47)

$\lim_{k \rightarrow \infty} \int_1^k \frac{1}{r^2} dr = \int_1^{\infty} \frac{1}{r^2} dr$
 Atty Ricman's integration
 $\int_1^{\infty} \frac{1}{r^2} dr = \left. -\frac{1}{r} \right|_1^{\infty}$
 Exci 1) $\frac{1}{(1+|x|)^{n+\alpha}} \in L^1(\mathbb{R}^n)$ for $\alpha > 0$
 2) $e^{-|x|^2} \in L^1(\mathbb{R}^n)$ ($b_0 e^{-|x|^2} \leq c \frac{1}{(1+|x|)^{n+1}}$ or $e^{-|x|^2}$ is a majorant)

Exci 1) $\frac{1}{(1+|x|)^{n+\alpha}} \in L^1(\mathbb{R}^n)$ for $\alpha > 0$
 2) $e^{-|x|^2} \in L^1(\mathbb{R}^n)$ ($b_0 e^{-|x|^2} \leq c \frac{1}{(1+|x|)^{n+1}}$ or $e^{-|x|^2}$ is a majorant)
 $\int_{\mathbb{R}^n} e^{-|x|^2} d\mu(x) = \int_{\mathbb{R}^n} e^{-x_1^2} \cdots e^{-x_n^2} d(x_1, x_2, \dots, x_n)$
 m_1 - Lebesgue measure in \mathbb{R}

So, that directly tells us that this is equal to integral 1 to infinity r to the n plus 1 to the. So, we have r to the n minus 1. So, this is simply 1 by r square dr and that is finite. So, you can integrate this to be minus 1 by r from 1 to infinity and this is, this will give us some, some quantity, finite quantity. Well you may want to justify this. So, this is something, which we have done before you can always write this as limit k going to infinity integral 1 to k, 1 by r square dr, because this is a positive function.

So by monotone convergence theorem, this is exactly equal to integral 1 to Infinity $1/r^2$ by MCT and here you can apply Riemann integration. So, apply Riemann integration because we are on a interval, this is a continuous function etc, Riemann integration and you can compute the limit. So, instead of doing this, you can do this in $1/r^k$ and take limit.

So, that is the standard method. So, we have seen this before. So, apply the same thing. So, you will get that this is finite. So, what we have proved is the function is an L^1 . So, let me give you an exercise here, you can do the same thing with a functions, which are very similar. So, $1/\sqrt{x}$. So, instead of $n+1$, take $n+\alpha$, prove that this is in $L^1 \mathbb{R}^n$ for α positive.

So, that is what you should understand. So, at infinity it should decay like $1/n^\alpha$, for α positive. So, faster than $1/n$ should decay like that, then only you will have. So, instead of r^2 here, you will have $r^{1+\alpha}$ and still the same thing will work. You can also check that e^{-x^2} is an L^1 this is much easier, because exponential decay is very fast.

So, this follows immediately, because e^{-x^2} is less than or equal to some constant times $1/n^\alpha$ to any power you want in particular you can put in $n+1$ or any other bigger power or any other bigger power. So, you will get L^1 immediately. Well this allows us to compute something. So, let us, let me try to explain that I leave the computation to you.

So, this is a positive function, it is a positive function and it is in L^1 . So, integral $\mathbb{R}^n e^{-x^2} dx$. So, dx , well this I can write as, so I will write it as integral over \mathbb{R}^n , e^{-x^2} is, $e^{-x_1^2}$, into $e^{-x_2^2}$, into etc $e^{-x_n^2}$. Because x^2 is a sum of x_j^2 . But now \mathbb{R}^n remember these are Borel measurable functions.

So, I can write \mathbb{R}^n , if I write \mathbb{R}^n as $\mathbb{R} \times \mathbb{R} \times \mathbb{R}$. So, this is product's face. So, you have a product measure and this are Borel measurable function. So, I can replace this with d of m , m_1 cross, m_1 cross, m_1 , n times, where m_1 is the Lebesgue measure, Lebesgue measure in \mathbb{R} or on a \mathbb{R} on the real line. So, you take the n fold product of that that is your Lebesgue measure on \mathbb{R}^n . So, we have seen that, $\mathbb{R}^n \times \mathbb{R}^n$ has Lebesgue measure m plus n dimensional Lebesgue

measure, restricted to Borel sigma algebra, there is no problem otherwise you completed appropriately.

(Refer Slide Time: 13:08)

The image shows a whiteboard with handwritten mathematical notes and equations. The main equation is:

$$\sigma(S^{n-1}) \int_0^\infty e^{-r^2} r^{n-1} dr = \left(\int_{\mathbb{R}} e^{-x_1^2} dx_1 \right) \left(\int_{\mathbb{R}} e^{-x_2^2} dx_2 \right) \dots \left(\int_{\mathbb{R}} e^{-x_n^2} dx_n \right)$$

Annotations include:

- "LHS apply Polar - coordinates to get" with an arrow pointing to the left-hand side.
- "RHS apply Fubini's theorem" with an arrow pointing to the right-hand side.
- "Compute from two integrals and consequently find $\sigma(S^{n-1})$ " with arrows pointing from the intermediate steps back to the main equation.
- A diagram of a sphere S^1 with a shaded cross-section.
- Below the sphere, the following calculation is shown:

$$\begin{aligned} \sigma(S^1) &= 2\pi \text{ (with ball in } \mathbb{R}^2) \\ &= 2\pi \end{aligned}$$

So, let us use this to compute this on the, on the left hand side, we can apply polar coordinates, apply polar coordinates to get well what is left hand side, integral 0 to infinity, e to the minus r square, remember it is a function of mod X. So, there is no omega dependence r to the n minus 1, dr times sigma of S n minus 1. So, that is a total measure of S n minus 1.

Well on the right hand side. So, let put this here, RHS apply Fubini's theorem, because we have a positive function. So, order of integration does not matter, Fubini's theorem. So, then this becomes integral over R e to the minus x1 square, dx1, dx1 meaning dm1 x1, I will simply write dx1, you fill Riemann integral notation, integral over R e to the minus x2 square dx2, etc etc. Because this, these are independent of each other, so they all come out as constants.

You can integrate in any order. So, that is called Fubini's theorem tells you. So, this gives me e to the minus xn square dxn. But these integrals are all same x1, x2, x3 are all dummy variables. So, this is simply integral over R, so I simply use y, e to the minus y square dy and then I have end of them, so to the n.

So, you can compute both sides. So, you can compute this and this. So, compute these two, so can do that by these two integrals, you will get expressions in gamma and so on, gamma and n

factorial and things like that and then you will get an expression for this. So, I will leave it to you and consequently and consequently find the total measure of S^{n-1} . You can check that it agrees with whatever you know in \mathbb{R}^2 . For example, if I look at \mathbb{R}^2 , I have the circle and the measure of the circle, in with respect to sigma.

So, this will be S^1 , sigma of S^1 , by definition is two times, n times the Lebesgue measure of the sectors, sector is the whole unit sphere, unit ball. So, unit circle or unit ball in \mathbb{R}^2 , unit ball in \mathbb{R}^2 has radius 1. So, you know what the area is. So, area is πR^2 , R is 1. So, just π , so this will be 2π , 2π is the circumference of the circle of radius 1. So, that is precisely what the measures. So, you can compute this and check that it is true. So, that will give an expression for sigma S^{n-1} in general. So, it is another application.

(Refer Slide Time: 16:32)

The image shows a whiteboard with handwritten mathematical notes. At the top left, it says "Ex 6.3". The main derivation is as follows:

$$f(x) = |x|^{-\alpha} \chi_{\{|x| \leq 1\}} \quad \alpha > 0$$

$$\int_{\mathbb{R}^n} |x|^{-\alpha} \chi_{\{|x| \leq 1\}} dx \stackrel{\text{like measure}}{=} \int_{\mathbb{R}^n} |x|^{-\alpha} dx$$

$$= \sigma(S^{n-1}) \int_0^1 r^{-\alpha} r^{n-1} dr$$

$$= \sigma(S^{n-1}) \int_0^1 r^{n-\alpha-1} dr$$

Check that $f \in L^1(\mathbb{R}^n) \Leftrightarrow \alpha < n$

Recall Calculations: $\int_0^1 \frac{1}{r^k} dx$

So, one more exercise, consider the function of $f(x)$ equal to $|x|^{-\alpha}$ now. α is positive times $|x|$ less than or equal to 1. So, I am looking at the characteristic function of $|x| \leq 1$ and multiplying by $|x|^{-\alpha}$, α positive. Let us see when is in L^1 .

So, if I want to integrate this, so I am going to integrate $|x|^{-\alpha} \chi_{\{|x| \leq 1\}}$ over \mathbb{R}^n , dx . So, dx here this is a Lebesgue measure, Lebesgue measure. But in so in the because of the indicator function, the integral is not on over \mathbb{R}^n , it will be on the

set. So, this is simply integral mod X less than or equal to 1, mod X to the minus alpha. I can also do that dx, apply polar coordinates, because I have a function of mod x again, there is no dependence on omega.

So, I will get that sigma n minus 1 outside as earlier. Now, I am on mod X less than or equal to 1. So, if it is a Rn I go from 0 to infinity, because of this I will go only from 0 to 1, r to the minus alpha times r to the n minus 1 dr, remember that extra measure there. So, this is equal to sigma S n minus 1 which is a constant, integral 0 to 1, r to the. So, let me write this as n minus alpha times r to the minus 1 dr.

Now check that, so you can again, so recall how we did recall calculating, calculating integral of 0 to 1, 1 by root x dx, it is an unbounded function. So, similarly depending on what alpha is this can be unbounded. But then you can always cut it at 1 by K and look at 1 by K to 1, apply monotone convergence theorem to compute this. So, you do that.

So, check that, check that, f is in L1 of Rn, if and only if alpha is less than n. So, I should have something positive here. Remember here there is a minus 1, R to the minus 1 is not integral, 1 by r dr will give me log r and then there is a problem at 0. But the moment I have something for some positive power here, it would be integral. So, that is the, that is the, so that is the point. So, that is a simple competition, but that you can use polar coordinates Fubini's theorem etc to do.

(Refer Slide Time: 19:39)

Convolution on \mathbb{R}^n : $f, g \in L^1(\mathbb{R}^n)$. Convolution of f and g is defined to be

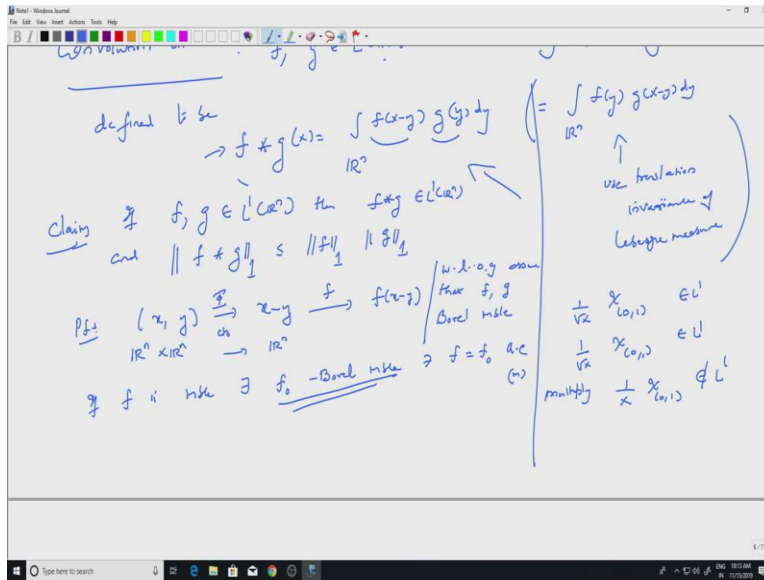

$$f * g(x) = \int_{\mathbb{R}^n} f(x-y) g(y) dy$$

Claim: If $f, g \in L^1(\mathbb{R}^n)$ then $f * g \in L^1(\mathbb{R}^n)$ and $\|f * g\|_1 \leq \|f\|_1 \|g\|_1$

Pf:

$\int_{\mathbb{R}^n} f(x-y) g(y) dy = \int_{\mathbb{R}^n} f(y) g(x-y) dy$
 (use translation invariance of Lebesgue measure)

$\frac{1}{\sqrt{x}} \chi_{(0,1)} \in L^1$
 $\frac{1}{\sqrt{x}} \chi_{(0,1)} \in L^1$
 multiply $\frac{1}{x} \chi_{(0,1)} \notin L^1$

So, another application. So that is called convolution, convolution on \mathbb{R}^n . So, we will use Fubini's theorem again. So, let us take f and g in L^1 of \mathbb{R}^n . Convolution of f and g is defined to be it is another function. So, we will denote it by $f * g$. So, $f * g$ at x equal to integral over \mathbb{R}^n , $f(x - y)g(y)dy$, we will justify it. So, of course this is also equal to integral over \mathbb{R}^n , $f(y)g(x - y)dy$.

So, that follows from use translation invariance of, translation invariance of, invariance of Lebesgue measure. So, that is a usual change of variable you will do and remind integration, you put $x - y$ is equal to t . Then dx, dy , equal to dt etc. So, that kind of change of variable, but that does that is essentially translation invariance of Lebesgue measure.

So, the claim is that, of course we do not know whether it excess or not, I have L^1 function. So, if I multiply to L^1 functions, I need not be L^1 . So, that is something, you should always keep in mind. For example you look at $1/\sqrt{x}$ inside $(0, 1)$. So, times $(0, 1)$, this is L^1 , I know and again you take $1/\sqrt{x}$ is also in L^1 , if I multiply, multiply I will get $1/\sqrt{x}$ into $1/\sqrt{x}$ is $1/x$. But $1/x$ is not integrable near 0 .

So, it is not in L^1 . So, I do not what happens to this integral, just because there is a translation, you will see that it excess almost everywhere. So, let us see that, so what you do is you start with. So claim, claim is that if f, g are in L^1 of \mathbb{R}^n . Then f convolved with g , is also in L^1 in \mathbb{R}^n . So, this is rather interesting, because the productive L^1 functions, need not be in L^1 . But the

moment you translate and then take the product and integrate you are going to get something in L^1 , which means that the integral of this.

So, it is an L^1 . So, it has to be finite almost everywhere. So, this integral exists for almost all x , we will see why and so it is not just that the convolution is in L^1 , the L^1 norm of f convolve with g is less than or equal to L^1 norm of f times L^1 norm of g . So, there is a bound as well, so let see the proof of this sought of state forward.

So, we have the convolution definition here, so we use that. So, problem here is f and g are not positive and so on. So, we will simply work with mod f and mod g . So, you look at mod f of x minus well first of all measurability. So, I should tell you why. So, f and g are in L^1 . So, they are Lebesgue measurable and I am taking the product. So, I need to show that, that is measurable and then take the integral.

So, there is x, y and so on so what you do is you look at the map x, y going to $x - y$. So, let us call that ϕ , so ϕ is continuous, well where is the map going from. So, this is \mathbb{R}^n cross \mathbb{R}^n which is \mathbb{R}^n to \mathbb{R}^n going to \mathbb{R}^n this is a continuous map and then you compose with f , which is a measurable function.

So, to get f of $x - y$, of course we do not know if there is a measurable, this map may not be measurable we do not know that, because f is only Lebesgue measure. But recall the theorem we proved yesterday in the last lecture, that if f is measurable, there exists a Borel measurable, Borel measurable, such that f equal to f almost everywhere with respect to the Lebesgue measure.

So, I can replace f and g with Borel measurable functions. So, without loss of generality so I should do that first, without loss of generality, assume that, assume that f and g are Borel measurable, Borel measurable. We can do that because if f and g are Lebesgue measurable, there are Borel measurable functions, which are equal to them almost everywhere and the integrals do not change. So, this, this expression will not change except on a set of measure 0, which we can discard.

(Refer Slide Time: 25:26)

f is not $\exists f_0$ - Borel measurable $\rightarrow f^{-1}(0)$ multiply $\frac{1}{x}$ $\notin L^1$

$(x, y) \xrightarrow{f} z = y \xrightarrow{f} f(x, y) \leftarrow$
 $\mathbb{R}^2 \times \mathbb{R}^2 \rightarrow \mathbb{R}^2 \rightarrow \mathbb{R}/\mathbb{C}$
 $f \circ \mathbb{I}: \mathbb{R}^{2n} \rightarrow \mathbb{R}/\mathbb{C}$ is not
 $V \subseteq \mathbb{R}/\mathbb{C}$ then then

$(f \circ \mathbb{I})^{-1}(V) = \mathbb{I}^{-1}(f^{-1}(V))$
 $\in \mathcal{B}(\mathbb{R}^{2n})$ \rightarrow $f^{-1}(V) \in \mathcal{B}(\mathbb{R}^n)$
 \rightarrow $\mathbb{I}^{-1}(f^{-1}(V)) \in \mathcal{B}(\mathbb{R}^{2n})$

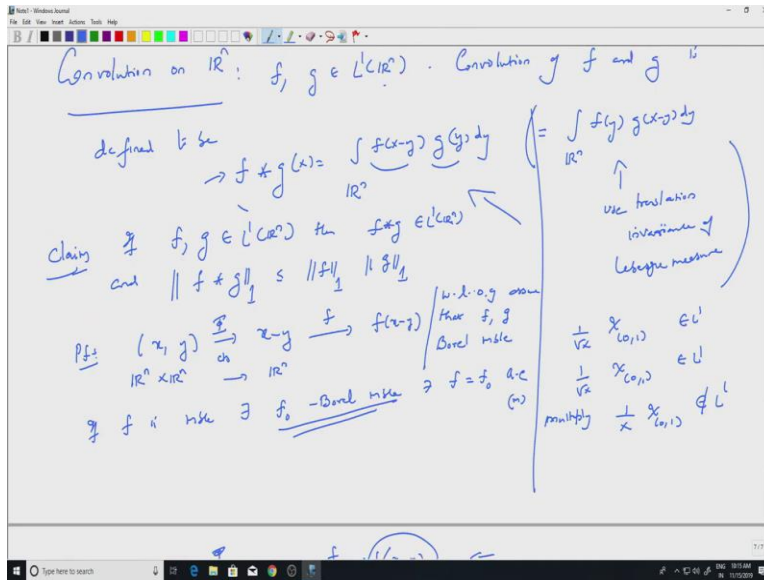

$\in \mathcal{B}(\mathbb{R}^{2n})$ \rightarrow $\mathbb{I}^{-1}(f^{-1}(V))$

Now consider $z \rightarrow \int_{\mathbb{R}^n} |f(x, y)| |g(y)| dy$
 $\in L^1(\mathbb{R}^n)$ if finite a.e.

$\int_{\mathbb{R}^n} \left(\int_{\mathbb{R}^n} |f(x, y)| |g(y)| dy \right) dx$
 Positive f's, so apply Fubini's th.

$\int_{\mathbb{R}^n} |g(y)| \left(\int_{\mathbb{R}^n} |f(x, y)| dx \right) dy$
 $\rightarrow \left(\int_{\mathbb{R}^n} |f(x)| dx \right)$

$= \|f\|_1 \|g\|_1 < \infty$

So, now if I go back to this, this map, so I have x comma y going to x minus y , which is, which is a continuous map, this is a continuous map and f , which takes to f of x minus y . So, this is a Borel map, Borel measurable. So, I am going from \mathbb{R}^n cross \mathbb{R}^n to \mathbb{R}^n to \mathbb{R} or \mathbb{C} or whatever does not really matter and I want to know, if this map is measurable, what exactly is this map?

This is f compose with ϕ , from \mathbb{R}^{2n} to real line or complex plane depending on what f is, well this is measurable, because ϕ is measurable, why is that? Well if I take if V is an open set contained in the real line or complex plane, open then I need to look at the inverse image of V and see where I land.

So, f compose with ϕ , inverse of V , I want to know whether this is a Lebesgue set or not. So, this is equal to well this is ϕ inverse of f inverse of V . Well what can I say about f inverse of V , f is a Borel function. So, it is function from \mathbb{R}^n to \mathbb{R} or \mathbb{C} , so it is the function from \mathbb{R}^n to \mathbb{R} or \mathbb{C} . So, f inverse V if I pull back a open set by a Borel measurable function, I will land in the Borel sigma algebra of \mathbb{R}^n .

Now ϕ continuous and so it will pull back, Borel sets to Borel sets. So, ϕ inverse of f inverse V , because this is a Borel set will be in, in the Borel sigma algebra \mathbb{R}^n , because ϕ is from \mathbb{R}^{2n} to \mathbb{R}^n . So, this is in the Borel sigma algebra \mathbb{R}^{2n} and so this is this function is f of x minus x y going to f of x minus y is a Borel function, Borel measurable function, similarly for g , g y .

So, you can integrate them, so integral makes sense it may not excess, we do not know that. So, consider, so now consider the integral of \mathbb{R}^n modulus of f of x minus y , modulus of g y dy , well what is the advantage in taking modulus, because it is a positive function and the integral will excess, it may be infinity but it will excess, modulus does not do anything to the measurability.

Now, if you look at this function, this is a function of x , this is well defined. I want to know whether this is finite or not, for that I look at one more integral, integral over \mathbb{R}^n and this function. So, that is integral over \mathbb{R}^n , modulus of f of x minus y , g y modulus dy and dx . So, all these are Lebesgue measures by the way. So, I am not writing m , we simply write because there are different variables dm_x and dm_y would have been okay, but you know dx , dy will denote Lebesgue measure, on the corresponding spaces.

But now I have two integrals, but it is these are positive functions, positive functions. So, apply Fubini's theorem, Fubini's theorem, these are all sigma finite measures, measures spaces I have positive functions. So, I can apply Fubini's theorem, so we will get integrate.

(Refer Slide Time: 29:39)

$\in \mathcal{B}(\mathbb{R}^n)$
 Now Consider $\int_{\mathbb{R}^n} |f(x-y)| |g(y)| dy$
 $\in L^1(\mathbb{R}^n)$ if finite a.e.
 $\int_{\mathbb{R}^n} \left(\int_{\mathbb{R}^n} |f(x-y)| |g(y)| dy \right) dx$ (Lebesgue measure)
 Positive f's, so apply Fubini's th.
 $\int_{\mathbb{R}^n} |g(y)| \left(\int_{\mathbb{R}^n} |f(x-y)| dx \right) dy = \|f\|_1 \|g\|_1 < \infty$

$G \in L^1(\mathbb{R}^n)$ if f and g are
 Fubini's theorem

$$\int_{\mathbb{R}^n} |f(x-y)g(y)| dx dy = \|f\|_1 \|g\|_1 < \infty$$

$\Rightarrow f * g \in L^1(\mathbb{R}^n)$
 $\|f * g\|_1 \leq \|f\|_1 \|g\|_1$

So, it does not matter, what order I integrate, so instead of integrating with respect to y first, I will integrate with respect to x , this g has nothing to do with x . So, that comes out. So, I will have modulus of g y and then I will have integral over \mathbb{R}^n mod of f of x minus y , dx , dy . So, that is just Fubini's theorem.

But what is this the Lebesgue measure is translation in variance. So, if I translate the function and integrate I will get the integral of the function. So, this is equal to integral over \mathbb{R}^n , mod f of x dx . So, in Riemann integration you will put x minus 1 equal to something and etc etc.

So, same thing which is translation in variant of in variance of Lebesgue measure. But now this is constant which has nothing to do with y and I have L^1 norm of g . So, this become L^1 norm of f times L^1 norm of g , correct, which is finite because f and g are in L^1 . So, if I look at this function. So if I look at this function this is in L^1 and so it is finite almost everywhere, and so it is finite almost everywhere. So, we so just one more step, so this you can conclude that f convolved with g , is actually in L^1 and L^1 norm of f convolved with g .

Now, is less than or equal to because taking the modulus, inside, you will get this, this quantity which is L^1 , norm of f into L^1 norm of g . So, we will stop here. So, we just saw some simple applications of Fubini's theorem and polar coordinates. So, we will continue a little bit more using Fubini's theorem and then we will go to a new topic called the complex measures.
