**Complex measures II**

So, in the last lecture we saw Complex Measures and total variation associated to a complex measure and we proved that the total variation is actually a positive measure. So, it is countably additive, so we have just shown that, it is countably additive. The next important result about total variation is that, it is actually a finite measure. So, mod  $\mu$ , when  $\mu$  is a complex measure, mod  $\mu$  is a positive finite measure.

So, strictly speaking, positive infinite measures are not contained in the collection of complex measures, only positive finite measures will be there, the positive infinite measures are not really considered as complex measures. But that is not very important but one should keep the distinction in mind. So, let us start.

(Refer Slide Time: 01:24)

So, far we have proved that, if we have a complex measure, complex measure, then we have mod  $\mu$ , which is a positive measure. So, the measure theorem we want to prove in this session is that, mod of  $\mu$  is a finite measure, a finite measure of course it is a positive measure. So, what does that mean? That is, that is so remember we have  $X, F, \mu$ , where  $\mu$  is a complex measure,

complex measure and  $\mu$  is a finite measure, meaning the total measure of  $\mu$  is a finite number.

So, it is a finite positive number, so we will start with the technical lemma. So this has nothing to do with measure theory it is a complex analysis lemma. So, let us take complex numbers set 1, set 2, etc., set  $n$ , complex numbers, complex numbers, then so there are capital  $N$  many complex numbers, then there exist a subset we will call that  $S$  contained in 1, 2, 3, etc, capital  $N$ . So, we are saying, we can choose a subset, so that some inequality is true.

So what you do? You look at  $Z_k$ , where  $k$  in  $S$ . So,  $S$  is a subset of 1 to up to  $N$ . So, you choose some of them and take this sum of this and that is greater than or equal to  $1$  by  $\pi$ , well  $1$  by  $\pi$  is a constant which comes out in the proof, it is not really important for our prove that  $\mu$  is a finite measure, but there is, there is a  $1$  by  $\pi$  there, summation  $k$  equal to 1 to  $N$   $\mu(Z_k)$ .

So, this is a technical lemma. So, let us prove this first, so this is easy, so we can choose some subset that is what we want to find out. So, write  $Z_k$  to be  $\mu(Z_k)$ , so that is a polar coordinates in the complex plane times  $e$  to the  $i$   $\alpha_k$ ,  $\alpha_k$  is a the argument of  $Z_k$  the angle. So,  $\alpha_k$  I can, so we will choose  $\alpha_k$  to be less than between minus  $\pi$  and  $\pi$ , that is allowed, for  $\theta$  in minus  $\pi$ ,  $\pi$ , define.

Let  $S_\theta$ , so  $S$  is going,  $S_\theta$  is going to be a subset of 1, 2, up to  $N$ . So, this is all  $k$  such that  $\cos$  of  $\alpha_k$  minus  $\theta$  is positive. What is  $\alpha_k$ ?  $\alpha_k$  is the argument of  $Z_k$ , well we will see why, all this is right now it might look arbitrary but the proof will immediately tell you why. Now, our idea is to choose the  $\theta$ , so that  $S_\theta$  will work in the lemma. So, in the lemma we need this inequality, we are going to show to that for some  $\theta$ , the  $S_\theta$  will work.

(Refer Slide Time: 05:12)

The whiteboard shows the following derivation:

$$\left| \sum_{k \in S(\theta)} z_k \right| = \left| \sum_{k \in S(\theta)} e^{-i\theta} z_k \right| \geq \operatorname{Re} \left( \sum_{k \in S(\theta)} e^{-i\theta} z_k \right)$$

$$= \sum_{k \in S(\theta)} |z_k| \cos(\alpha_k - \theta)$$

$$= \sum_{k=1}^N |z_k| \cos(\alpha_k - \theta)$$

Choose  $\theta_0$  such that  $RHS$  is maximized.

$$\left| \sum_{k \in S(\theta_0)} z_k \right| \geq \sum_{k=1}^N |z_k| \cos(\alpha_k - \theta_0) \geq \frac{1}{2\pi} \int_{-\pi}^{\pi} \left( \sum_{k=1}^N |z_k| \cos(\alpha_k - \theta) \right) d\theta$$

$$= \frac{1}{\pi} \sum_{k=1}^N |z_k| \int_{-\pi}^{\pi} \cos(\alpha_k - \theta) d\theta$$

Calculate  $\int_{-\pi}^{\pi} \cos(\alpha_k - \theta) d\theta = 2$

So, let us sum over  $S$  theta,  $k$  belonging to  $S$  theta  $Z_k$ . So,  $k$  belonging to  $S$  theta  $Z_k$ . So, I am trying to sort of bound this, getting a lower bound for this. Well, this is equal to, theta as of now is fixed. So, I can multiply this with  $e$  to the  $i$  theta modulus of  $E$  to the  $i$  theta is 1. So, it does not change anything, so I can say  $k$  in  $S$  theta and the  $e$  to the  $i$  theta has nothing to do with the summation.

So, I put well  $E$  to the minus  $i$  theta  $Z_k$  modulus, this is of course greater than or equal to, so modulus of a complex number is greater than or equal to the real part of the complex number. So, it is real part of summation  $k$  in  $S$  theta  $E$  to the minus  $i$  theta  $Z_k$ . So, again so far we have not done anything non trivial, which is equal to. So, what is the real part of a complex number that is the cosine of whatever is, whatever the angle is. But  $Z_k$  is mod  $Z_k$  times  $E$  to the minus  $i$  alpha  $k$ .

So, when I multiply by  $E$  to the minus  $i$  theta, I will have a minus theta here. So, I will get mod  $Z_k$  to the  $E$  to the  $i$  alpha  $k$  minus theta and when I look at the real part, I am going to get the cosine. So, this is simply summation  $k$  in  $S$  theta mod  $Z_k$ , of course that is, that will be there and you have  $\cos$  alpha  $k$  minus theta. So, notice that  $S$  theta is all those  $k$  such that  $\cos$  alpha  $k$  minus theta is positive.

So, this is a positive quantity and I will, I will write it in terms of the function  $\cos$ . So, this is  $k$  equal to  $1$  to  $N$ . So, now I am going from  $1$  to  $N$ , mod  $Z$  to the  $k$  of course all the  $k$ s do not come there,  $S$  theta is such that this is true. So, whenever  $\cos \alpha k$  minus theta is less than or equal to  $0$ , I want it to be  $0$ . So, that is precisely the positive part of the function.

So, I look at  $\cos$  plus  $\alpha k$  minus theta. So what is  $\cos$  plus?  $\cos$  plus is the positive part of the function, positive part like  $f$ , for any measurable function we define  $f$  plus and  $f$  minus. So, there is, this is just the  $f$  plus positive part of the function  $\cos$ . So, for whenever this is negative I have  $0$ . So, that is why the summation is over  $k$  in  $S$  theta.

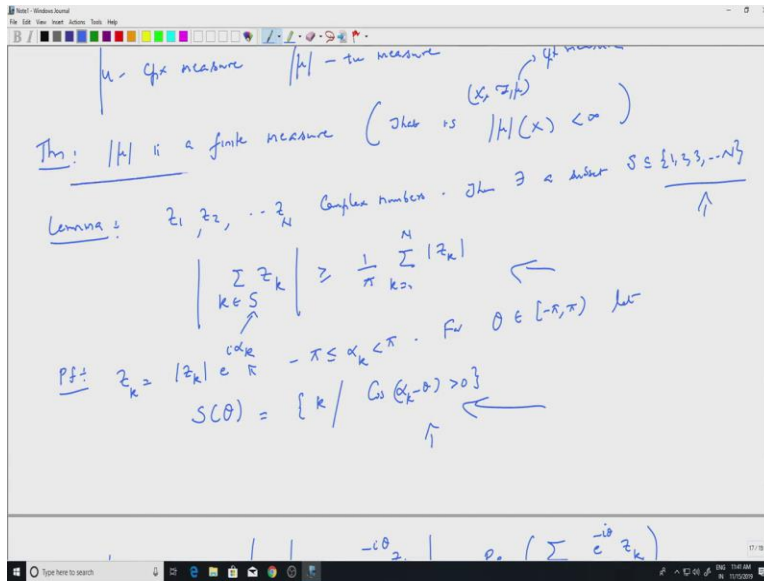

But now choose, so choose theta naught such that. So, this is sum inequality, so sum like this is greater than or equal to whatever is here. So, you choose theta naught such that RHS is maximum, RHS is maximized, well you can think of this as a continuous function if you want and you are looking at a compact interval. So, there is sum theta naught for which the RHS is maximized. But then this maximum is, this maximum is greater than or equal to some integral.

So, I will write this here, so this is greater than or equal to, so maybe I should write one more line here. So,  $S$  so summation  $k$  in  $S$  theta naught  $Zk$  modulus is greater than or equal to summation  $k$  equal to  $1$  to  $N$ , mod  $Zk$   $\cos$  plus  $\alpha k$  minus theta naught. So, the right hand side is the maximum value you can get. So, this is surely greater than or equal to  $1$  by  $2\pi$  integral minus  $\pi$  to  $\pi$   $d$  theta.

So, this is just one, so I am only taking the maximum of the function outside. So, this is, so I will write this as summation  $k$  equal to  $1$  to  $N$  mod  $Zk$ . Now, I simply write  $\cos$  plus of  $\alpha k$  minus theta  $d$  theta. So, think of this as a function of theta then this is the maximum of the function. So, that can come out and you will have this minus  $\pi$  to  $\pi$   $1$  by  $2\pi$  will give me  $1$ . So, this is true.

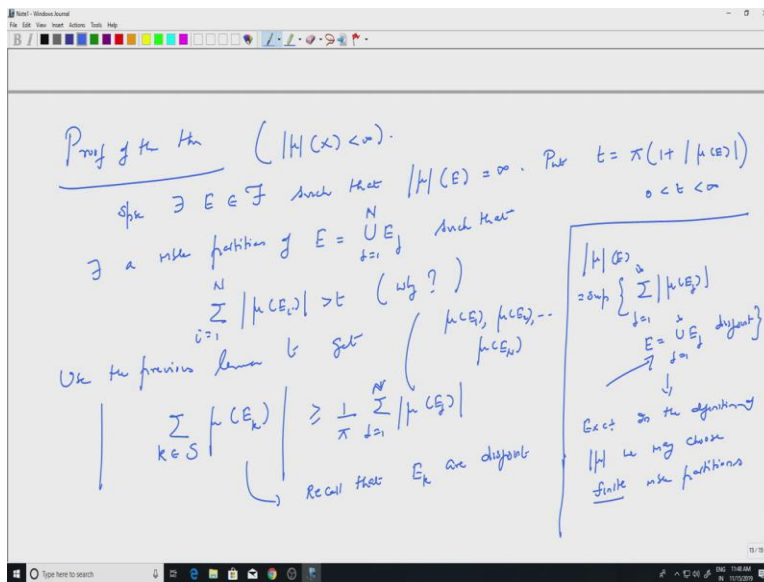

So, now this is easy, so this equal to, so you calculate this integral. So, you can for each theta, for each  $\alpha k$  you know how to calculate this, because  $\alpha k$   $\cos$  plus  $\alpha k$  minus theta is  $\cos$  of  $\alpha k$  minus theta when it is positive and is  $0$  otherwise. So, you write down the integral, you can calculate this to get this to get  $1$  by  $\pi$  summation  $k$  equal to  $1$  to  $N$  mod  $Zk$ . So, calculate this, calculate  $1$  by  $2\pi$  minus  $\pi$  to  $\pi$   $\cos$  plus  $\alpha k$  minus theta  $d$  theta. So, you will, you will get the answer then.

(Refer Slide Time: 11:00)

So, there technical lemma is done we are trying to prove that mod mu is a finite measure. So, proof is by contradiction, so let us, let see that.

(Refer Slide Time: 11:18)

So, proof of, proof the theorem. So, we are trying to prove that, so mod mu is a finite measure. So, mod mu of X is finite is what we want to prove. So, suppose, suppose there exist some set E in script F such that mod mu of E is infinity, if it is not finite measure of course it will be infinity on some set, maybe it is infinity, on the whole space. But let us start with sum set E.

Put sum constant  $t$  equal to  $\pi$  times,  $\pi$  because the  $\pi$  is there in that technical lemma,  $1 + \text{modulus of } \mu \text{ of } E$ .

So, do not get confused  $\text{mod } \mu \text{ of } E$  and  $\text{modulus of } \mu \text{ of } E$  are different. Now, because  $\mu$  is a complex number. So,  $\text{mod of } \mu \text{ of } E$  is a finite positive quantity. So,  $t$  is a finite positive quantity. So, there exist a partition, there exist a measurable partition of  $E$ , we will write this in the finite, as a finite union, it can be an infinite union, but you can cut it down to a finite union, we will see why. Such that, such that  $\sum_{i=1}^N \text{modulus of } \mu \text{ of } E_i$  is greater than  $t$ . Well, why is that?

So, let us, let us recall everything  $\text{mod } \mu \text{ of } E$  was defined to be supremum over  $\sum_{j=1}^{\infty} \text{modulus of } \mu \text{ of } E_j$ , where  $E$  was written as  $\bigcup_{j=1}^{\infty} E_j$ , measurable partition,  $j$  equal to  $1$  to infinity. So, disjoint measurable sets, so instead of choosing an infinite partition, I am choosing a finite partition, because any such sum can be, any such sum can be approximated by, by a finite sum.

So, that is the reason one can replace an infinite sum by a finite sum. Even in the, in fact even in the definition, so of this is an exercise, you can change the in the definition of  $\text{mod } \mu$  in the, in the definition of  $\text{mod } \mu$ , we may choose, we may choose finite measurable partitions. So, measurable partition, so that means I do not need to write this as  $\bigcup_{j=1}^{\infty}$ , I can go up to finitely many sets and that we will do, because any infinite sum these are all finite quantities.

So, infinite sum can be approximated by finite sum. So, that is the reason, so anyway this is something, which you can check, after the proof of this it will be much, much clearer, because this is, these are finite measures. So, these are all finite convergence series and so you can, you can always approximate the infinite series by a finite series. So, you will have a measurable partition with this, this property.

So, I will leave it to you, why? We use the property of the supremum. So, now, so this is like finitely many positive numbers. So, complex numbers taken modulus with, so use the lemma, use the previous lemma, use the previous lemma, to get, so if you use the previous lemma, so I

am applying previous lemma the previous to the complex numbers  $\mu E_1, \dots, \mu E_N$ , etc  $\mu E_n$ .

So, finitely many complex numbers,  $Z_1, Z_2, \dots, Z_n$ , then I have a subset of 1 to N, such that sum of these things. So, I will get a subset, let us say S such that  $k \in S$  and I am adding these complex numbers, modulus of this is greater than or equal to 1 by pi summation  $j$  equal to 1 to N or  $k$  equal to 1 to N mod  $\mu E_j$ . This is what we have, but the  $E_j$ s are disjoint. So, recall that  $E_k$  are disjoint,  $E_k$  are disjoint. So, this sum will become, the sum, the measure of the union.

(Refer Slide Time: 17:06)

$$|\mu(\bigcup_{k \in S} E_k)| \geq \frac{1}{\pi} \sum_{k \in S} |\mu(E_k)| \geq \frac{t}{\pi} > 1$$

Call this set A.

$$|\mu(A)| > 1$$

Let  $B = E \setminus A$ . Then

$$|\mu(B)| = |\mu(E) - \mu(A)| \geq |\mu(E)| - |\mu(A)| \geq \frac{t}{\pi} - 1 = 1$$

$$t = \pi(1 + |\mu(E)|)$$

$$E \ni |\mu(E)| = \infty \quad E = \text{AUB disjoint}$$

such that  $|\mu(A)| \geq 1 \quad |\mu(B)| \geq 1$

Proof of the thm ( $|H(x)| < \infty$ ).

spk  $\exists E \in \mathcal{F}$  such that  $|\mu(E)| = \infty$ . Pick  $t = \pi(1 + |\mu(E)|)$

$\exists$  a finite partition of  $E = \bigcup_{k=1}^N E_k$  such that

$$\sum_{k=1}^N |\mu(E_k)| > t \quad (\text{why?})$$

Use the previous lemma to get  $\{ \mu(E_k), \mu(E_k), \dots, \mu(E_k) \}$

$$|\sum_{k \in S} \mu(E_k)| \geq \frac{1}{\pi} \sum_{k \in S} |\mu(E_k)|$$

Recall that  $E_k$  are disjoint

Exact to the definition of  $H$  we may choose finite measurable partitions

So, on the left hand side, we will have modulus  $\mu$  of union  $k \in S E_k$  because they are disjoint, greater than or equal to  $1$  by  $\pi$  summation  $j \text{ equal to } 1 \text{ to } N \text{ mod } \mu \text{ of } E_j$ , which of course is greater than or equal to  $t$  by  $\pi$ , which is greater than  $1$ . So, greater than  $1$  is the important part. So, let see why it is greater than  $t$  by  $\pi$ , because it is, because this sum is greater than  $t$  and I have a  $1$  by  $\pi$  here.

So, that will give me  $t$  by  $\pi$ , and  $t$  by  $\pi$  is of course greater than  $1$ , because  $t$  is chosen like this. So,  $t$  by  $\pi$  is greater than  $1$ . So, what did we get? We got, so let us call this set  $A$ , call this set  $A$ . So,  $A$  is contained in  $E$ , remember  $E$  is a set we started with and  $E$  is the set we started with,  $E$  we wrote as a finite partition, disjoint union of finitely many measurable sets and from that there is some selection which gives us the set  $A$ . It is a set contained in  $E$ , it is union of sum  $E_j$ .

So, what we have got is,  $A$  which is a subset of  $E$  measurable such that  $\mu$  of  $A$  is greater than  $1$ . Now, if  $B$  is the complement of  $A$  inside  $E$ , then well what is  $\mu$  of  $B$ ?  $\mu$  of  $B$  is  $\mu$  of  $E$  minus  $\mu$  of  $A$ , because  $A$  and  $B$  are disjoint. So, this is, let say this is  $E$ , I am getting some set  $A$ , which is a union of  $E_j$ s and the compliment is  $B$ . So, measure of  $B$  is the measure of total measure minus measure of  $A$ .

So, modulus of this will be equal to modulus of this, which is of course greater than or equal to  $\text{mod } \mu A \text{ minus } \text{mod } \mu E$ . So, that is always true, if I have two complex numbers, this greater than or equal to  $\text{mod } w \text{ minus } \text{mod } Z$ , or  $\text{mod } Z \text{ minus } \text{mod } w$ , it does not really matter, which is of course greater than or equal to. So, I know this is set  $A$ , so I have  $t$  by  $\pi$  here as a lower bound minus  $\text{mod } \mu E$  which is equal to  $1$ .

So, this is the you just have to remember the expression for  $t$ , from this if I look at  $t$  by  $\pi$  minus  $\text{mod } \mu E$ , that is  $1$ , because  $t$  was, remember  $t$  was  $\pi$  times  $1$  plus  $\text{mod } \mu E$ . So,  $t$  by  $\pi$  minus  $1$ , that is  $t$  by  $\pi$  minus  $\text{mod } \mu$ , that is just  $1$ . So, what did we do? We got  $A$  contained in  $E$  such that  $\text{mod}$  of  $\mu$  is greater than  $1$ , the compliment  $B$  also has the property that  $\text{mod}$  of  $\mu B$  is greater than  $1$ .

So, let us write that as a separate sentence, so we started with  $E$  such that  $\text{mod } \mu$  of  $E$  is infinite. What did we do? We got  $E$  as  $A$  union  $B$  disjoint such that, such that modulus of  $\mu$  of  $A$  is

greater than 1, modulus of mu of B is greater than or equal to 1. So, I can put the greater than equal to 1, it does not really matter. So, that is a, so that we can apply again and again.

(Refer Slide Time: 21:47)

Now suppose that  $\mu(X) = \infty$   
 $\Rightarrow X = A_1 \cup B_1$  disjoint  $\mu(A_1) \geq 1$  and  $\mu(B_1) \geq 1$   
 with  $\mu(A_1) = \infty$   
 Continue  $A_1 = A_2 \cup B_2$  disjoint  $\mu(A_2) \geq 1$  and  $\mu(B_2) \geq 1$   
 $\mu(A_2) = \infty$   
 Continue this to get a seq  $B_1, B_2, B_3, \dots$  disjoint such that  $\mu(B_j) \geq 1 \forall j$

$\mu(B) = \mu(A) + \mu(B)$   
 $\geq \frac{t}{\pi} - \mu(B) = 1 \Rightarrow |t-1|$   
 $t = \pi(1 + \mu(B))$   
 $E \Rightarrow \mu(E) = \infty$  such that  $\mu(A) \geq 1$  and  $\mu(B) \geq 1$   
 $E = A \cup B$  disjoint

Now suppose that  $\mu(X) = \infty$   
 $\Rightarrow X = A_1 \cup B_1$  disjoint  $\mu(A_1) \geq 1$  and  $\mu(B_1) \geq 1$

So, now suppose, so now suppose that mod mu of x is infinity, we are trying to prove that this is finite and so we trying to get a contradiction, suppose mod mu of x is infinity. So, we have X and we can partition it to two parts. So, I have A which I will call A1, and I will call B1 here. So, using the earlier one we will get X as a union of A1 B1, disjoint, disjoint but importantly both of them will have modulus of their measure greater than 1.

And so both their sets, this is what we just proved, for any set with infinite mod  $\mu$  measure I can disjointify them, such that each portion has measure greater than or equal to 1. So, I do that for mod  $\mu$  X. So, now one of them should have infinite measure. So, let me write it here, mod  $\mu$  X, mod  $\mu$  X, so this is the infinity part, well, it is a measure. So, it is mod  $\mu$  of  $A_1$  plus mod  $\mu$  of  $B_1$ .

So, one of them will have to be infinity, so we will assume that this infinity. So, I can do this with, with mod  $\mu$  of  $A_1$  to be infinity. So, I can continue, continue well if you continue what happens? So,  $A_1$  is the set which has infinite mod  $\mu$  measure, I can partition it. So, now I will get  $A_2$  and  $B_2$ .

So, we will get  $A_2$  and  $B_2$ . So,  $A_1$  can be written as  $A_2$  union  $B_2$  disjoint of course with what is the property? We are using the previous step, if I have a set with mod  $\mu$  measure infinity, I can disjointify them. So, that  $\mu$  of  $A_2$ , greater than or equal to 1, mod  $\mu$  of  $B_2$  greater than or equal to 1 and of course one of them will have to have infinite measures. So, we will assume it to be  $A_2$  and mod  $\mu$  of  $A_2$  is infinite.

So, we continue this, so continue, so what are we getting if you continue? Continue this to get a sequence  $A_1, A_2, A_3$ , etc. So, I should be more, more careful here. So, I am writing X as  $A_1$  union  $B_1$  disjoint, I get, I get  $A_1$  mod, mod of  $\mu$   $A_1$  is greater than equal to 1, mod of  $\mu$   $B_1$  is also greater than 1. So, maybe the sets should be very clear, so I start with  $B_1$ , so I am getting a sequence of  $B$ s rather than  $A$ s, because that is what will give a contradiction.

So,  $B_1, B_2, B_3$ , etc. So, I have  $B_1$ , I have  $B_2$  and then well this is the one which has infinite measures. So, it decomposes with  $A_3$  and  $B_3$ . So,  $B_1, B_2, B_3$ , are disjoint. So, this is a disjoint sequence, disjoint such that, such that modulus of  $\mu$   $B_j$  is greater than or equal to 1 for every  $j$  at each, each step, we have that both the pieces have measure greater than or modulus has greater than, value greater than 1. So, we are getting a sequence of disjoint sets such that the measure, modulus of the measure is greater than 1.

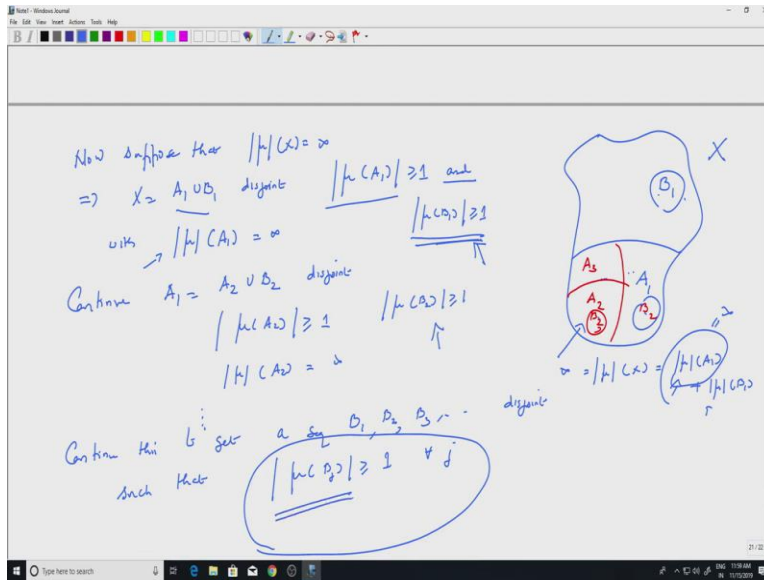

(Refer Slide Time: 26:55)

$|H(A_2)| = \dots$   
 Continue this to sets such that  $B_1, B_2, B_3, \dots$  disjoint  
 $|H(A_2)| \geq \sum_j \mu(B_j)$   
 $|H(A_2)|$

$B = \bigcup_{j=1}^{\infty} B_j \in \mathcal{F}$   
 $\mu(B) = \sum_{j=1}^{\infty} \mu(B_j)$   
 this should converge  $\Rightarrow \mu(B_j) \rightarrow 0$  as  $j \rightarrow \infty$

Proof of the thm ( $|H(A)| < \infty$ ).  
 s.t.  $\exists E \in \mathcal{F}$  such that  $|H(E)| = \infty$ . Pick  $t = \pi(1 + |H(E)|)$   
 $0 < t < \infty$   
 $\exists$  a finite partition of  $E = \bigcup_{i=1}^N E_i$  such that  
 $\sum_{i=1}^N |H(E_i)| > t$  (why?)  
 Use the previous lemma to get  $\mu(E_1), \mu(E_2), \dots, \mu(E_N)$   
 $\left| \sum_{k \in S} \mu(E_k) \right| \geq \frac{1}{\pi} \sum_{i=1}^N |H(E_i)|$   
 Recall that  $E_k$  are disjoint

$|H(E)| = \sum_{i=1}^{\infty} |H(E_i)|$   
 $E = \bigcup_{i=1}^{\infty} E_i$  disjoint  
 Exact to the definition  
 $|H|$  is  $\pi$  times  
 finite  $\mu$  partitions

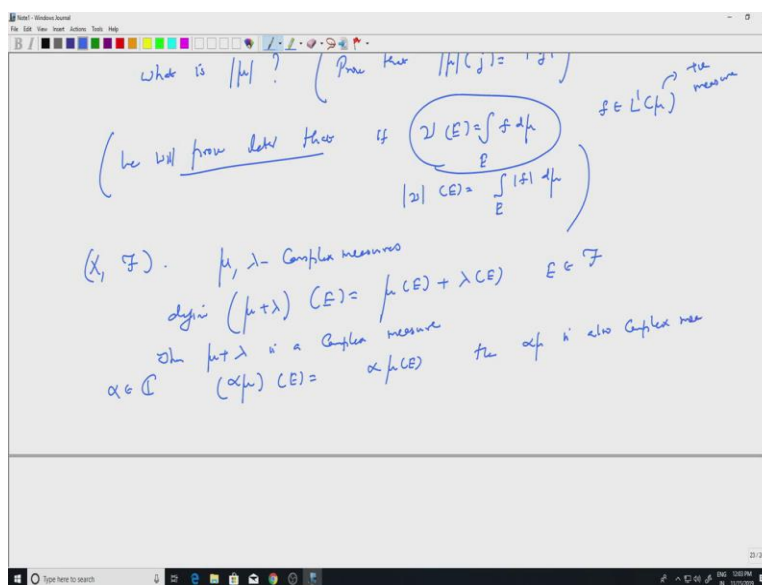

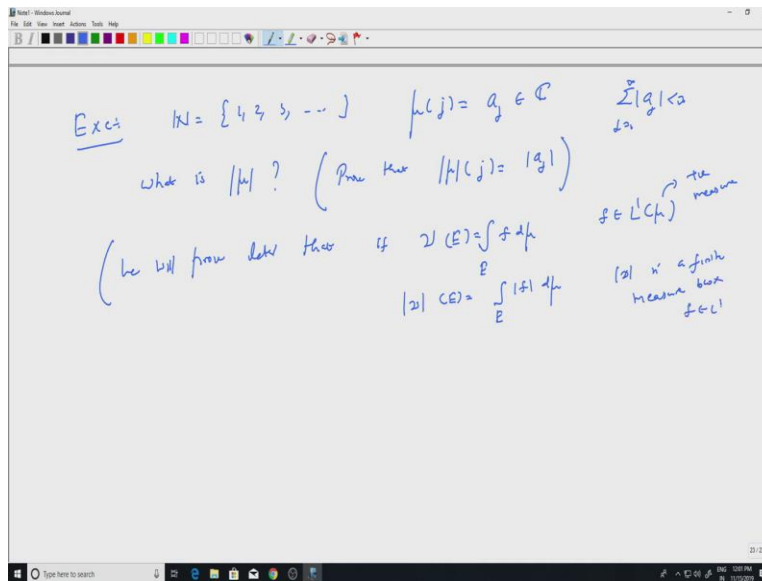

So, now if you look at union  $B_j$ ,  $j$  equal to 1 to infinity, let us call that  $B$ , of course this would be a measurable set, what did you know about  $\mu B$ ? Well,  $\mu B$  because these are disjoint this will have to sum up,  $j$  equal to 1 to infinity,  $\mu$  of  $B_j$ . But this converges, converges, so this converges, this should converge, converge otherwise it will not make sense, it converges absolutely in fact, it should converge, which implies that  $\mu$  of  $B_j$  go to 0.  $n$ th term will go 0, as  $n$  goes to infinity, that if you have a convergence series.

But that is not possible because modulus of  $\mu B_j$  is greater than or equal to 1 for every  $j$ . So, it cannot be go to 0, so that is a contradiction. So, we started with let me just repeat it once more, we started with a set with  $\text{mod } \mu$  equal to infinity, first thing we did was to decompose  $E$  into two sets where both of them have modulus measure greater than 1. Now, one of them will have infinite measures.

So, you continue this, so while continuing this you get a sequence of disjoint sets whose modulus, measure of the, modulus of the measure is greater than or equal to 1. But that is not possible because the union will should have, should have the measure which is the sum and the sum should converge that is part of the definition of the complex measure and so it should converge the  $N$ th term should converge to 0, which will contradict whatever inequality we have got here.

(Refer Slide Time: 28:49)

So, let us before we finish, let us look at some example. So, or let me write this is an exercise this is easy to do. Suppose I take my space to be the natural numbers and  $\mu$  of  $j$  I take to be  $a_j$  some complex number with summation  $\sum_{j=1}^{\infty} |a_j| < \infty$ . So, what is  $|\mu|$ ? So,  $|\mu|$  remember is a, is the total variation measure. So, you can prove that, prove that  $|\mu|$ , so  $|\mu|$  of singletons  $j$ , that is, that will do.

So, that is actually  $\sum_{j=1}^{\infty} |a_j|$ , you will see that this is true and that so that sort of explains why modulus is used. So, if you have function instead of a numbers you will see that modulus is

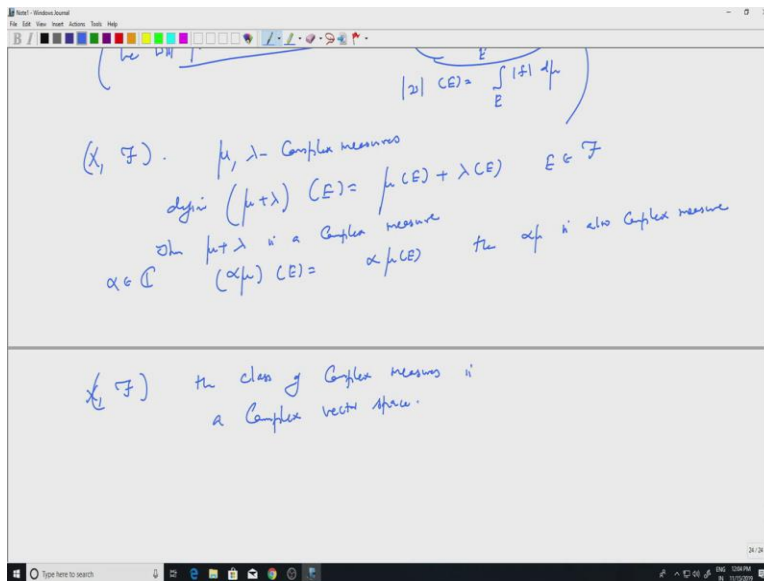

coming. So, let us let see we will prove later, we will prove later, that if, if I define  $\nu E$  to be integral over  $E$ ,  $\int f d \mu$ , where  $f$  is in  $L^1 \mu$ , where  $\mu$  is a positive measure, positive, if you want sigma finite positive measure.

But  $f$  can be complex value, then I know  $\nu$  is a complex measure,  $|\nu|$  is given by  $\int |f| d \mu$ . So,  $|f|$  is a positive function, since  $f$  in  $L^1$  this is a finite measure. So,  $|\nu|$  is a finite measure, which we know in general, because  $f$  is in  $L^1$ . But that is not, it is true in general, so let us a bit of, so this we will prove later, so that is why the modulus, in a sense the modulus sign or the notation is justified because of this and this, this set of measures from a rather important class which we will, we will see soon.

So, let us, let just look at the space of, so I have a space  $X$  and I have a sigma algebra  $\mathcal{F}$ , the collection of complex measures. Let us say I have two complex measures,  $\mu$  and  $\lambda$  complex measures. Then I can add them. So, define  $\mu + \lambda$ , so this is a new complex measure to be  $\mu(E) + \lambda(E)$  for any  $E$  in  $\mathcal{F}$ .

So, this make sense, so for every  $E$  in  $\mathcal{F}$ , then  $\mu + \lambda$  is a complex measure, then  $\mu + \lambda$  is a complex measure, that is trivial, all that you have to do, to check is if  $E_j$ s are disjoint  $\mu + \lambda$   $\cup B_j$  will be,  $\cup E_j$  will be sum. But that happens for each step, similarly you can multiply, so if I take a complex number now  $\alpha$  then  $\alpha \mu$  if you define this to be  $\alpha \mu(E)$ . So, that is also a complex measure, then  $\alpha \mu$  is also a complex measure. So, what we have just proved is, the space of complex measures is a complex vector space.

(Refer Slide Time: 32:36)

So, let us see, so if I have  $X, \mathcal{F}$  the class of complex measures is a complex vector space, is a complex vector space. So, we will stop here, we have just proved that the total variation measure is actually a finite measure. So, associated to any complex measure  $\mu$  we have  $|\mu|$  which is the total variation measure and that is a finite measure.

We will continue with complex measures in the next lecture as well. The measure result which we will prove in the next few lectures is the Radon-Nikodym theorem, which actually characterizes the measures, which we had written down. So, recall that we wrote down  $\nu$  of  $E$  to be integral over  $E$ ,  $f d\mu$ , such measures have a certain property, which is called the absolute continuity property, which is what we will define in the next, next session and we will classify such measures that is what is known as a Radon-Nikodym theorem. So, we will stop here.
