Absolutely continuous measures

So, in the last lecture we saw that the total variation measure associated to a complex measure is a finite measure. So, we will continue with the properties of complex measures, so we saw that the class of complex measures on a space they form a complex vector space, we will see that it actually coincides with linear functionals on the space depending on the structure on the space, whether locally compact (\cdot) (0:55) so on, which is the Riesz representation theorem but that will come after some lectures.

In the next couple of lectures, our aim is to prove what is known as Radon–Nikodym theorem, for that we need require what is known as absolute continuity property. So, we will start with such a definition but before the absolute continuity, let us quickly dispose of certain class of measures just to introduce that term.

The complex measure, out of the complex measures there are measures which are only real valued, they can be call the signed measures and one has a decomposition like the positive and the negative part of the function. So, I will start with that and then go to absolute continuity property.

(Refer Slide Time: 1:49)

So, let us start. So, we start with easy exercise, so define norm of μ to be mod μ of X , so prove that norm this is actually a norm, is actually a norm, on the space of complex measures on X . So, our setting is always I have X and \mathbb{F} and you look at all complex, space of complex measures. So, we know that this is a complex vector space, so this is a complex vector space and on that vector space I am putting a norm, so you just prove that this is a norm, so that is sort of straight forward.

Now, suppose μ is real-valued, so that means we have X and \mathbb{F} and μ remember a complex measure is function from \mathbb{F} to \mathbb{C} , but it can, it is possible that it ends up in the real line such a μ is called real valued. So, we will call μ , we will call such μ signed measures, so that is one term which you might encounter in some books, signed measures so it is not positive, well if it is strictly positive, it is a positive measure, otherwise it can also take negative values also.

So, for example the counting measure etc we had, so you can text X to be, let us take a finite set 1, 2, 3, 4 etc up to 10 and you can define a_1 to be 1, a_2 to be minus 1, a_3 to be minus 4, etc, etc up to a_{10} , some numbers. That will be a and then μ of (\cdot) would be simply add up these numbers depending on which member is in that set a . So, that will give a signed measure.

So, if these are complex numbers, then we will call it the complex measure. So, among complex measures, signed measures are the ones which take real values. So, if μ is a signed measure,

signed measure, well mod mu is still a positive measure. So, define, I can define mu plus, so this is going to be the positive part, so this is equal to half mod mu plus mu. So, it is very similar to what you will do in the case of numbers or the functions and so on.

So, recall that F plus is actually half of mod f plus f and f minus is similarly half of mod f minus f and mod f is actually f plus f, f minus and f is, sorry f plus plus f minus and f is f plus minus f minus. Similar equalities are true in the case of measures as well. So, mu minus you define it to be half mod mu minus mu, so both are positive measures because you are adding measures, subtracting measures, you will get measures.

But they are positive measures, positive measures that is because mod mu domain a is mu all the time. So, both the numbers are positive.

(Refer Slide Time: 6:04)

on the space of Complex measures on X

Complex valued space

• Since μ is real valued $(\mathbb{R}, \mathcal{F})$ $\mu: \mathcal{F} \rightarrow \mathbb{R}$ "signed measures"

we will call such μ - "signed measures"

μ signed measure define $\mu^+ = \frac{1}{2}(\mu + |\mu|)$ $\mu^- = \frac{1}{2}(\mu - |\mu|)$

$\mu = \mu^+ - \mu^-$ $|\mu| = \mu^+ + \mu^-$ "positive measures"

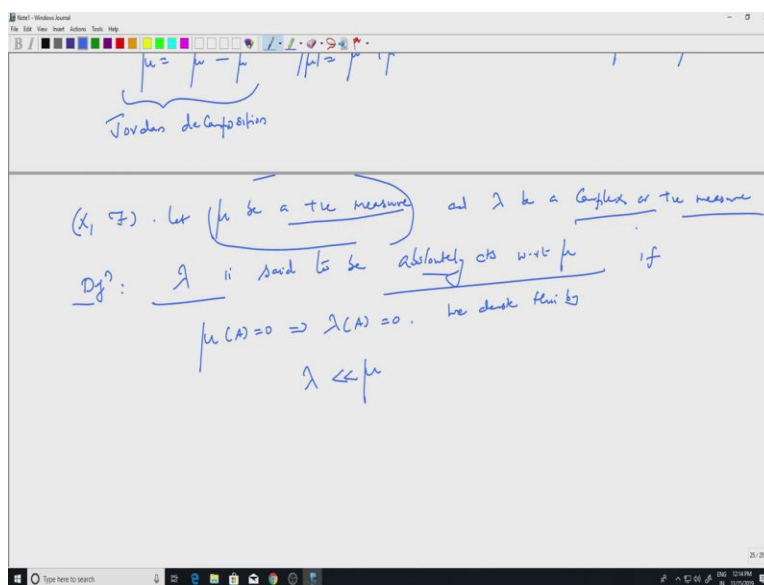

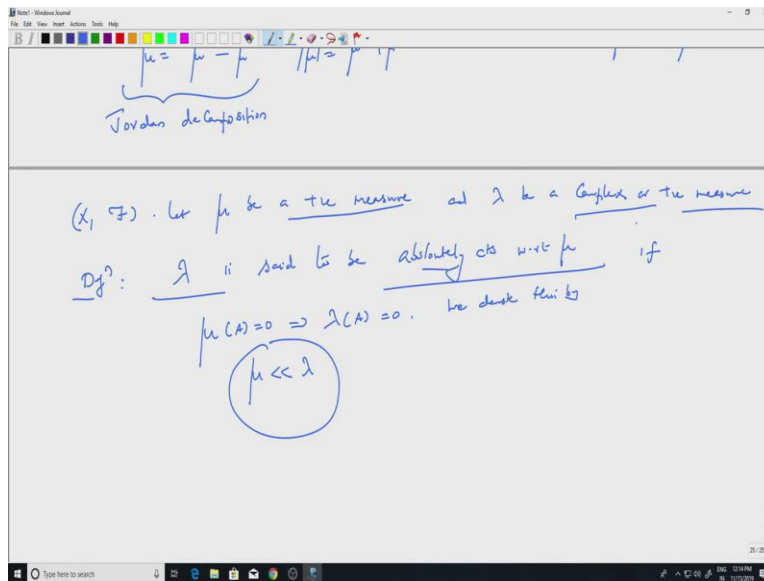

Jordan decomposition

$X = \{1, 2, -1, 0\}$
 $a_1 = 1$ $a_2 = -1$ $a_3 = 3$
 $a_0 = 100$

$f^+ = \frac{1}{2}(\mu + |\mu|)$
 $f^- = \frac{1}{2}(\mu - |\mu|)$
 $|\mu| = f^+ + f^-$
 $f = f^+ - f^-$

So, what is the big deal about the decomposition? So, you can write mu as mu plus minus mu minus and mod mu as mu plus plus mu minus, so this is exactly like this and this decomposition has a name so this is called a Jordan decomposition. It has a certain property which I will explain later. So, right now it is simply a decomposition.

(Refer Slide Time: 6:43)

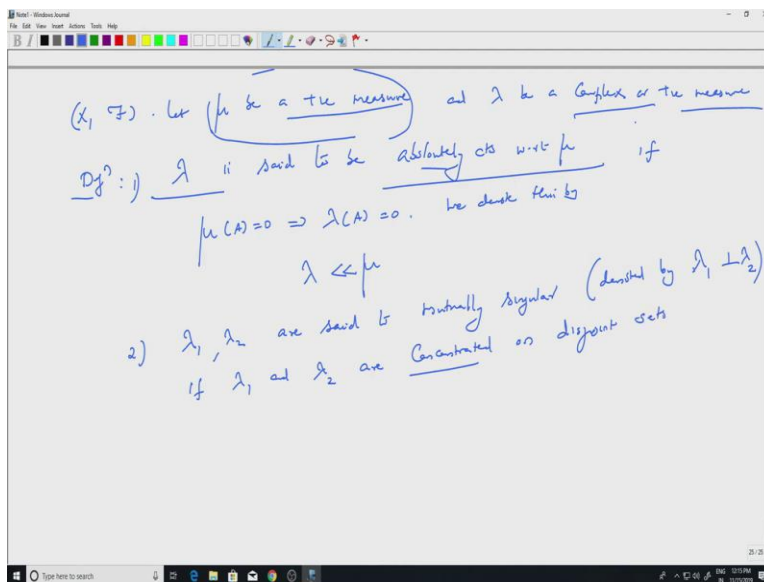

So, now our aim is to define absolutely continuous measures. So, we have space X, \mathcal{F} . Let μ be a positive measure, so remember this is a μ is a positive measure and λ be a complex or positive measure, so it can be complex or positive. So, positive finite measure is a complex measure, but positive infinite measures are strictly speaking, not a subset of complex measures that is why we keep saying complex or positive measure, like the Lebesgue measure on the real line is not a subset of, is not a complex measure in that sense because it has infinite measure.

So, definition. λ is said to be absolutely continuous with respect to μ , so this is the concept we want to define, absolutely continuous with respect to μ , if $\mu(A) = 0$ implies $\lambda(A) = 0$. So, whenever $\mu(A) = 0$, $\lambda(A)$ is also 0. So, we denote this by this symbol, $\lambda \ll \mu$. So, this means that it is absolutely continuous with respect to μ .

So, I wrote the other way, it is λ which is absolutely continuous with respect to μ . So, whenever $\mu(A) = 0$, $\lambda(A)$ should be 0. So, μ is positive, so the one with respect to absolutely continuous is defined has to be a positive measure, otherwise these things can go wrong that you will see more of it as we go along. So that is one definition.

(Refer Slide Time: 9:09)

The second one, if I have two complex measures, so λ_1 and λ_2 are said to be mutually singular, so that is the opposite concept of absolutely continuous, you will see this later when we do Radon–Nikodym theorem, mutually singular so this is this also has a notation denoted by $\lambda_1 \perp \lambda_2$. So, that is the notation for mutually singular measures. If λ_1 and λ_2 are concentrated on disjoint sets, so I should tell you what concentration means. So, let us define that separately.

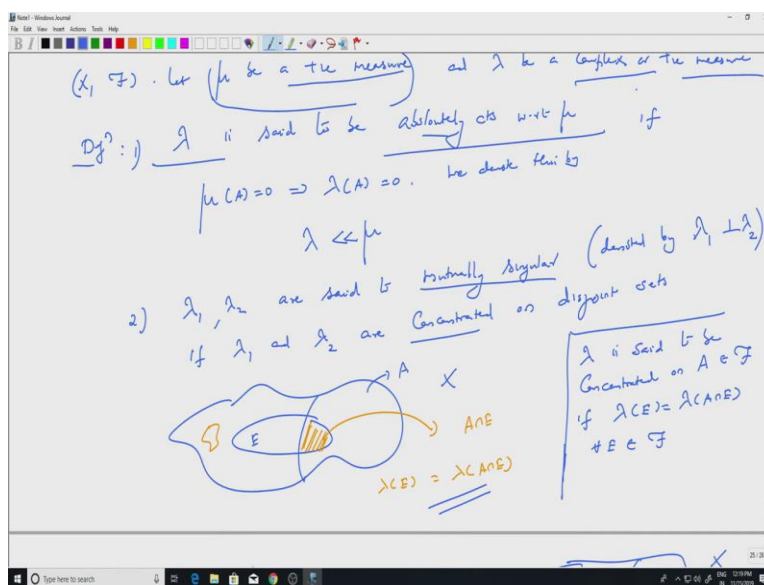

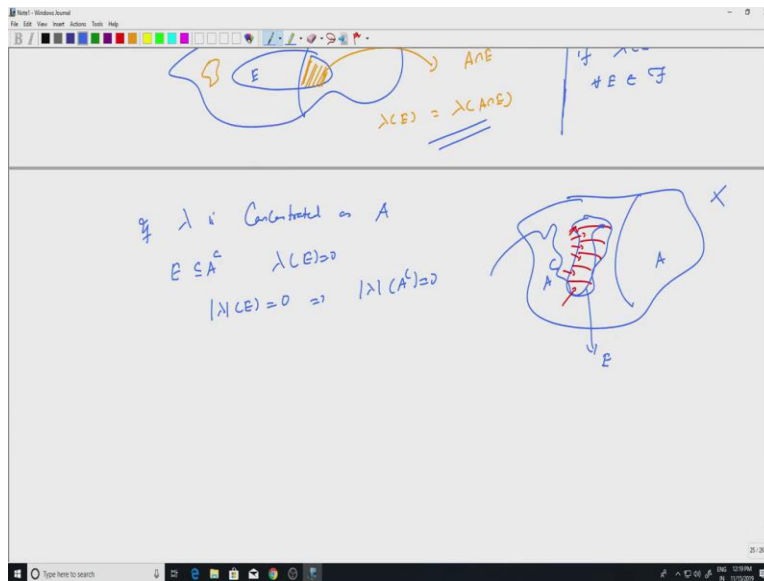

(Refer Slide Time: 10:11)

So, I should have written this before I defined mutually singular. So, let us say some measure is concentrated on a set that means it has no component outside. So, lambda is said to be concentrated, lambda is said to be concentrated on a set A , of course it has to be measurable on A if lambda of E equal to lambda of A in the section E for every E . So, the measure of E is obtained by looking at the part of E which is inside A , so that is why it is concentrated on A . So, let us draw some pictures then it will be clear.

So, let us say this is my space X and I have some set A here. So, lambda is concentrated here means, whatever E I take, so the E may go out of A , but only this portion matters, when I take lambda, so this is A intersection E and we are saying lambda of E equal to lambda of A intersection E . So, for any set which is here the lambda will be 0, for any set, so that is very important.

(Refer Slide Time: 11:54)

So, if I look at A complement, so if lambda is concentrated on A then, so let us draw this picture again so this is X, I have A and I have A complement here. You take any set which is contained in A complement so that is some set here E, then lambda of E is 0 because it does not intersect A and so this here you will get 0.

But what does that mean if I take any set E here, what about mod lambda of E? Well, that will also be 0 because what do you do to get mod lambda of E. So, let us draw E slightly bigger so

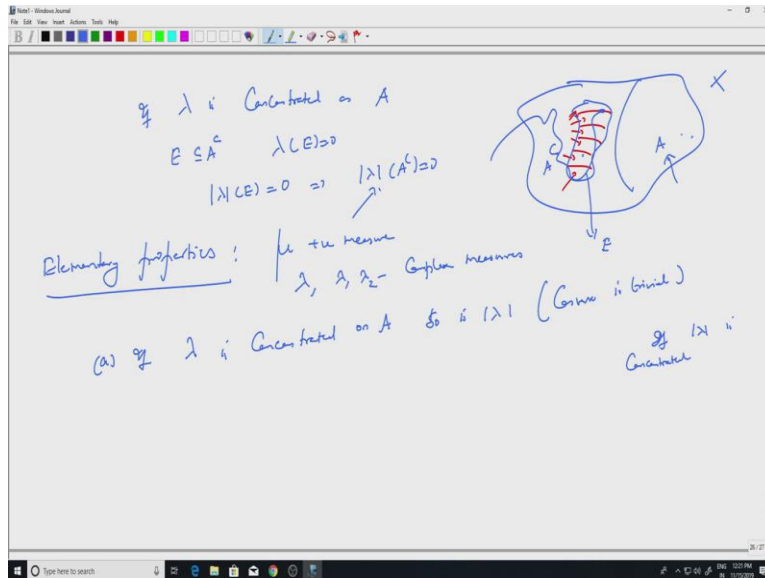

this is my set E, to get mod lambda you partition E, you look at measurable partitions of E and then add the modulus of measure of each of them.

But each of these piece is inside A complement, so it will have lambda of each if piece to be 0 and so when you add you will get 0. So, that is why you have mod lambda of E is 0. So, well, so this will also imply mod lambda of A complement itself is 0, so mod lambda is 0 here. So, concentration means that and mutually singular means they are concentrated on disjoint sets. So, think of them as functions supported on disjoint sets, so that would be analogy which we saw earlier as well.

(Refer Slide Time: 13:40)

Handwritten notes on a whiteboard:

- Top left: $E \subseteq A$
- Top middle: $|\lambda|(E) = 0 \Rightarrow |\lambda|(A^c) = 0$
- Top right: A diagram showing a set A and its complement A^c . A set E is shown inside A , and a set F is shown inside A^c . Arrows indicate the relationship between these sets.
- Middle left: Elementary properties: μ + measure, λ_1, λ_2 - Gelfand measures
- Middle: (a) λ is concentrated on A so is $|\lambda|$ (Conc is linear)
- Middle: (b) $\lambda_1 \perp \lambda_2$ then $|\lambda_1| \perp |\lambda_2|$
- Bottom middle: $\lambda_1 \perp \lambda_2 \Rightarrow \exists$ disjoint sets A_1, A_2 such that $\lambda_1 \perp \lambda_2$
- Bottom right: If $|\lambda|$ is concentrated on A then $|\lambda|(A^c) = 0 \Rightarrow \lambda(E) = 0$ if $E \subseteq A^c \Rightarrow \lambda$ is concentrated on A

So, some elementary proposition, so elementary properties. So, recall these definitions always. So, we will have μ positive measure, λ , λ_1 , λ_2 , complex measures. So, I will write down each property and prove that. So, most of this is trivial but this will also make you familiar with these mutually singular property and absolutely continuous property, so those two are the important properties.

So, first one, a, if λ is concentrated on A , so is $|\lambda|$, converse is trivial, so that is the, that is the observation we just made, if λ is concentrated on A then on A complement whatever measure you, whatever set you take that will have $|\lambda|$ measure 0, so $|\lambda|$ is also concentrated on A .

And if $|\lambda|$ is concentrated on A then it is 0 outside. So, since it is 0 outside any set will have measure 0, either with $|\lambda|$ or λ . So, maybe I can explain that part. So, if $|\lambda|$ is concentrated on, so that is one advantage with positive measures so if positive measures, if positive measures gives a set measure 0, any subset will have measure 0, but that is not true with complex measures.

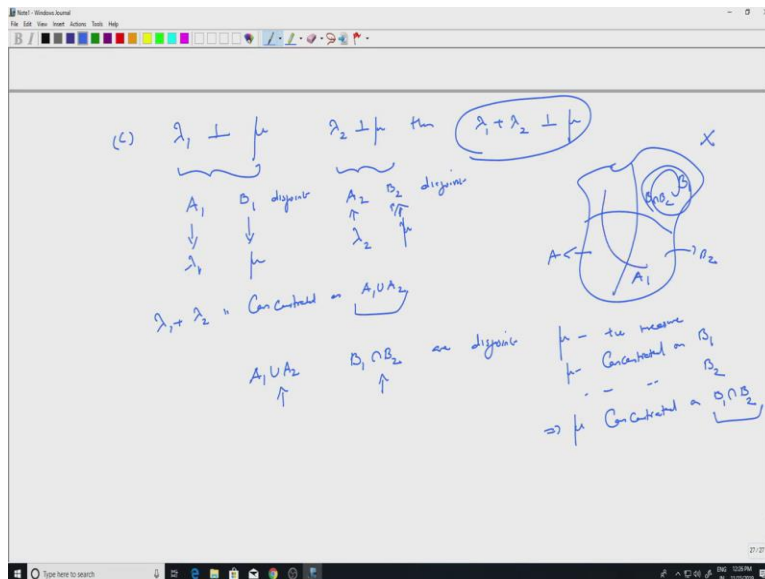

So, the total space may have measure 0 but smaller set can have positive or negative measure, the positive and negative get cancelled. So, if $|\lambda|$ is concentrated on A , then $|\lambda|$ of A complement is 0. So, this implies λ of E equal to 0 if E is contained in A

complement and that is what so this implies lambda is concentrated in A, so that is easy, so that is the first part. So, this we have already seen.

Second property, if lambda 1 is mutually singular to lambda 2, then mod lambda 1 is mutually singular to mod lambda 2. Well, that is because the support of, support meaning the concentration of lambda 1 and lambda 2 are same as concentration of mod lambda 1 and mod lambda 2.

So, lambda 1, so, let me write one line for this, lambda 1 mutually singular to lambda 2 implies there exists disjoint sets A and B, such that lambda 1 is concentrated on A, lambda 2 is concentrated on B. But if lambda 1 is concentrated on A the first one tells me that mod lambda 1 is also concentrated on A and mod lambda 2 is concentrated on B and A and B are disjoint, so that is always needed. So, that is an easy property.

(Refer Slide Time: 17:27)

Next one, lambda 1 is mutually singular to mu, so remember mu is a positive measure, lambda 1 is mutually singular to mu, lambda 2 mutually singular to mu, then lambda 1 plus lambda 2 is mutually singular to mu. So, here mu is positive that is very important. So, lambda 1 is, so let us say that.

So, let us say this is the space X. So, this tells me there are sets A 1 and B 1 disjoint and lambda 1 is concentrated on A 1 and mu is supported on B 1. So, we get A 1 and B 1. So, let us, so it

need not be the whole space but let us say this is A_1 and B_1 . So, this is for simplicity. Similarly we get disjoint sets A_2 and B_2 disjoint such that λ_2 is concentrated on A_2 and μ is concentrated on B_2 .

Well, so μ is a positive measure, so let us discuss that, so μ is positive measure and μ is concentrated on B_1 and μ is also concentrated on B_2 . So, outside B_1 it is 0, outside B_2 it is 0. So, outside the intersection also it is 0. So, then this implies μ is concentrated on $B_1 \cap B_2$.

And $\lambda_1 + \lambda_2$, so λ_1 is concentrated on A_1 , λ_2 is concentrated on A_2 . So, $\lambda_1 + \lambda_2$ is concentrated on $A_1 \cup A_2$, outside $A_1 \cup A_2$, that is $(A_1 \cup A_2)^c$, any subset will have measure 0. So, $A_1 \cup A_2$ and $B_1 \cap B_2$ they are disjoint, $A_1 \cup A_2$ and $B_1 \cap B_2$ are disjoint and that is precisely this thing $\lambda_1 + \lambda_2$ is concentrated here, μ is concentrated here, they are disjoint.

So, if you want a picture, you can let us say this is A_2 and this portion is B_2 , so then $B_1 \cap B_2$ is this. So, μ will be supported only here. And $A_1 \cup A_2$ is where the $\lambda_1 + \lambda_2$ is supported. So, that proves another property, so most of these are trivial properties, but we will use them every now and then.

(Refer Slide Time: 20:44)

(d) $\lambda_1 \ll \mu$ $\lambda_2 \ll \mu$ then $\lambda_1 + \lambda_2 \ll \mu$ | $\mu(E) = 0 \Rightarrow$
 $\lambda_1(E) = 0$
 $\lambda_2(E) = 0$
 $\Rightarrow (\lambda_1 + \lambda_2)(E) = 0$

(e) $\lambda \ll \mu$ then $(\lambda \ll \mu)$ $\mu(E) = 0$ - Want to show here
 E such that $\mu(E) = 0$
 $\lambda(E) = 0$
 $\lambda(E) = \sum_{j=1}^{\infty} \lambda(E_j)$ \uparrow $\mu(E_j) = 0$
 $= 0$ $\lambda(E_j) = 0 \Rightarrow \lambda(E) = 0$
 $E_j \subseteq E$
 $\mu(E_j) = 0 \Rightarrow \lambda(E_j) = 0$

(f) $\lambda \ll \mu$ $\lambda_2 \perp \mu$ then $\lambda_1 \perp \lambda_2$

$\lambda(E) = \sum_{j=1}^{\infty} \lambda(E_j)$ \uparrow $\mu(E_j) = 0$
 $= 0$
 $\lambda \ll \mu$ $\lambda_2 \perp \mu$ then $\lambda_1 \perp \lambda_2$
 $\lambda(E_j) = 0$

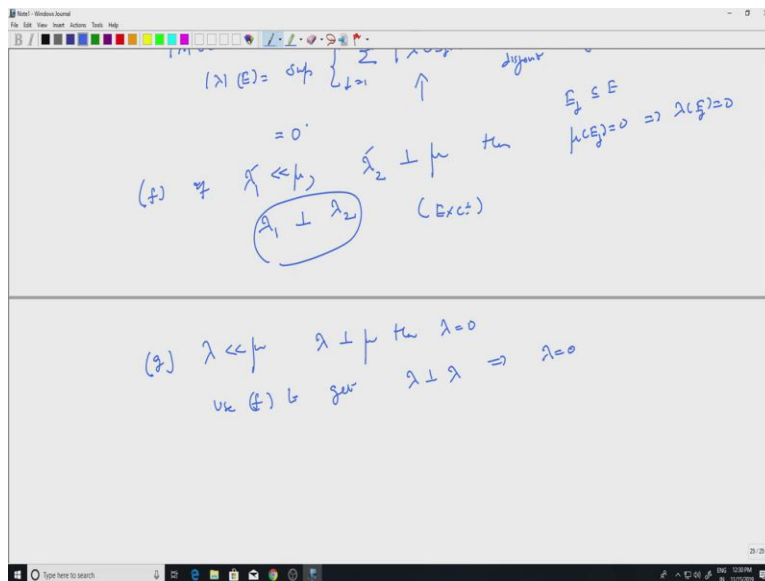

So, the next one, lambda 1 is absolutely continuous with respect to mu, lambda 2 is absolutely continuous with respect to mu, then lambda 1 plus lambda 2 is absolutely continuous with respect to mu, that is trivial. So, recall lambda 1 absolutely continuous with respect to mu meaning mu is a positive measure, mu E equal to 0 implies lambda 1 of E is 0 and the second one implies lambda 2 of E is equal to 0 that is the definition. So, this would imply lambda 1 plus lambda 2 of E is 0 and that is always needed. So, that is a trivial property E.

The next one, if λ is absolutely continuous with respect to μ , then remember μ is a positive measure, $\mu \ll \lambda$ is also absolutely continuous with respect to μ . Well, how do you prove this? So, take a set E such that $\mu(E) = 0$. Now, I want to say, so I want to show, I want to show that $\mu \ll \lambda$ of E is also 0.

But $\mu \ll \lambda$ of E , what is $\mu \ll \lambda$ of E ? Well, by definition this is supremum of various things, summation j equal to 1 to infinity modulus of λ of E_j union E_j equal to E , E_j are disjoint. But E_j are contained in E , so each E_j is contained in E , $\mu(E) = 0$, so $\mu(E_j) = 0$ because μ is a positive measure, but $\mu(E_j) = 0$ implies $\lambda(E_j) = 0$, because λ is absolutely continuous with respect to μ .

So, this sum is 0 and so supremum is 0. So, if λ is absolutely continuous with respect to μ then $\mu \ll \lambda$ is also absolutely continuous with respect to μ . So, if λ_1 is absolutely continuous with respect to μ , λ_2 is mutually singular with respect to μ , then λ_1 is mutually singular with respect to λ_2 . So, that I will leave as an exercise so this is sort of trivial.

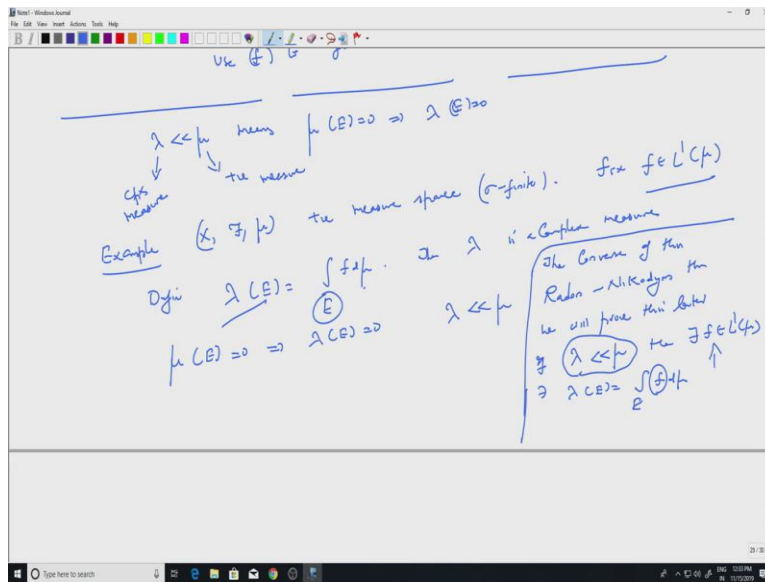

(Refer Slide Time: 23:42)

One more property λ is less than, well λ is absolutely continuous with respect to μ , λ perpendicular to μ , well, which means mutually singular then λ equal to 0, well that is sort of easy. So, use f to get, so use this. So, in this case λ_1 and λ_2 both are

lambda so you will get lambda is mutually singular with respect to lambda which itself implies lambda as 0, so that is a trivial conclusion.

(Refer Slide Time: 24:43)

So, let us look at one example and then we will be able to finish. So what is absolute continuity, let us go back to that. So, lambda is absolutely continuous with respect to mu means, mu of E equal to 0 implies lambda is 0. So, lambda is complex and mu is positive, so that is how we have defined. So, this is a positive measure, and this is a complex measure, we can define those for two positive measures also. So, I will elaborate on that later.

Now, how do we get examples? So, example. So, we start with a positive measure space X, F, mu, positive measure space sigma finite if you want. So, most of the time we will be using sigma finiteness. So, X, F, mu, so let us put sigma finite for whatever I am going to say this is not necessary but let us just put this.

Define, so let us define a new measure. Define lambda, so lambda of E, so we just saw this is equal to integral over E f d mu, so what is f? f is an L1 function, so fix f in L1. So, that can be a complex valued thing. So, this is a complex number. So, then we saw that, then lambda is a complex number, complex measure, lambda is a complex measure.

But then from the theory of integration we know that mu of E equal to 0 implies lambda of E equal to 0 if you integrate over a set which has measure 0, then you will get 0. So, this implies

that λ is absolutely continuous with respect to μ . The converse of this. So, let me write this here, the converse, so this is a trivial part.

The converse is highly non trivial, converse of this is called Radon–Nikodym theorem, so we will prove that, so we will prove this later, we will prove this later, in the next two classes should be proving this. So, what does it say? If I have, so this says that if ν is or less used λ just to be consistent with whatever we have just written.

So, if I have a complex measure λ which is absolutely continuous with respect to μ , then there exist some f in $L^1(\mu)$, such that $\lambda(E)$ is equal to integral over E of $f d\mu$, so we will be able to get f so that this works. So, whenever you have an f in L^1 you define this complex measure that turns out to be absolutely continuous with respect to μ .

The converse which is the Radon–Nikodym theorem says that, whenever you have λ which is absolutely continuous with respect to μ , there is an f which will give me λ as integral over E of $f d\mu$. So, that is what we will prove in the next, most probably in the next lecture or the lecture after that. So, we will stop here.

So, we have defined the complex measures, total variation measure, absolute continuity and mutually singular measures and we looked at various elementary properties of absolutely continuous and mutually singular property and we saw that absolutely continuous measures can be obtained by taking a function in L^1 of μ and integrating.

And in the next one or two lectures we will prove the converse which is called the Radon–Nikodym theorem which says that any absolutely, if I have a positive measure μ and λ is a complex measure which is absolutely continuous with respect to μ , there is an f in L^1 which defines this complex measure λ , f is called the Radon–Nikodym derivative, we will justify all this in the next two lectures. So we will stop here.
