**Riesz Representation Theorem**

Okay, so we will continue with the proof of the Riesz Representation Theorem. So, recall that we constructed a positive linear functional, we want to construct a positive linear functional  $\lambda$  on  $C_X$  which dominates  $\phi$ , we defined  $\lambda$ . We saw some properties of it, we are trying to prove that it is linear, okay. So, let us get back to the proof.

(Refer Slide Time: 00:53)

So, recall that we had all this, we looked at we proved one way inequality right and now, we want to prove that lambda of F1 plus F2 is less than or equal to lambda F1 plus lambda F2 for that we started with a general g which is in Ccx and bounded by F1 plus F2, right and that g got split into g1 and g2, okay.

With these 2 additional conditions, right, g1 is less than F1, g2 is less than F2, okay. So, that should help us in proving things. So, modulus of phi of g equal to modulus of phi of g1 plus g2, correct. Because g is g1 plus g2 and, well, phi is linear. So, I know this is less than that I can take the modulus and so on. So, g1 plus modulus of g2 because phi is linear and I take the modulus inside but phi of g1.

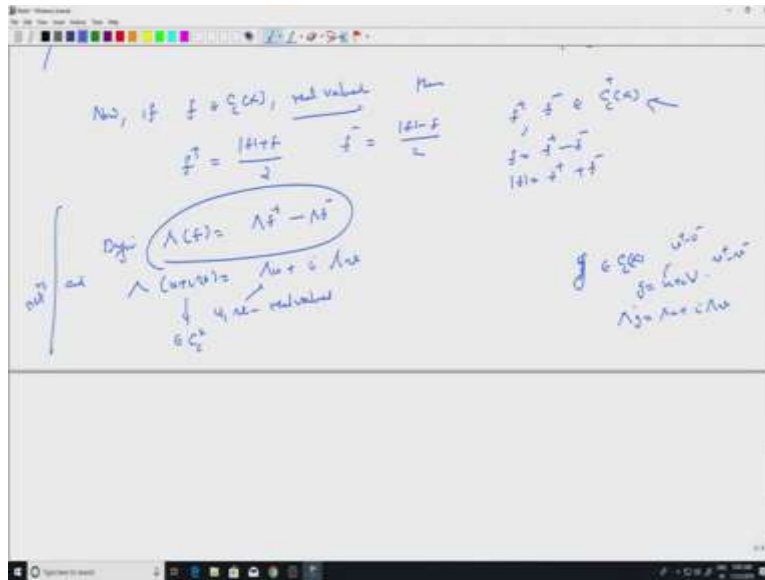

So, look at this inequalities, g1's are inside that set where you take supremum to define lambda for F1 right. So, this is less than to lambda of F1 plus lambda of F2, correct. But this is true for any g, which was in Ccx right, g was an arbitrary function gCx which split into g1 plus g2, but g was chosen such that mod g is less than or equal to F1 plus F2 and now, for such a g we are proving that mod Vg is less than or equal to these 2 addition of these 2 quantities.

So, I can take supremum over all such g right takes supremum over all such g, I will get lambda of F1 plus F2. So, hence lambda of F1 plus F2 is less than or equal to lambda of F1 plus lambda of F2, right that is what I wanted to say. So, this is the other inequality which we want and

putting together with the earlier inequality, we have lambda of F1 plus F2 is equal to lambda F1 plus lambda F2, but we have this only for some functions, right?

Not for all functions, for F1 and F2 inside Ccx plus, right, positive or non-negative functions, which are compactly support, but now you can extend it, okay.

(Refer Slide Time: 03:44)

So now, if so, this is what you have seen if you define something for positive functions, you can go to real functions and then to complex valued functions, right. So, we do that. So now if I take F in Ccx real valued, right, from positive or non-negative functions we are going to real valued functions.

If it is real valued then write F plus. So, you know what is F plus the positive part of F that is mod F plus F by 2 ofcourse and F minus is the negative part of F so, that is mod F minus F by 2 but both are positive functions, right. So, both F plus and F minus are continuous functions because the sum and difference of continuous functions, everything is compactly supported. So, all these are compactly supported functions, right.

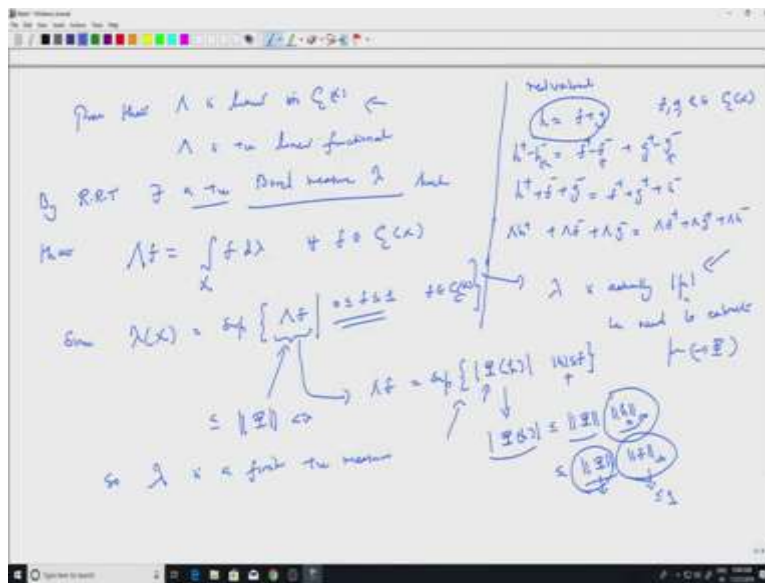

Not just that because it is F plus and F minus they are also positive right and F is equal to F plus minus F minus, right, and mod F is equal to F plus, plus F minus. So, we have seen all this. So, this tells me how to define lambda, right. So, define lambda of F to be lambda F plus, minus

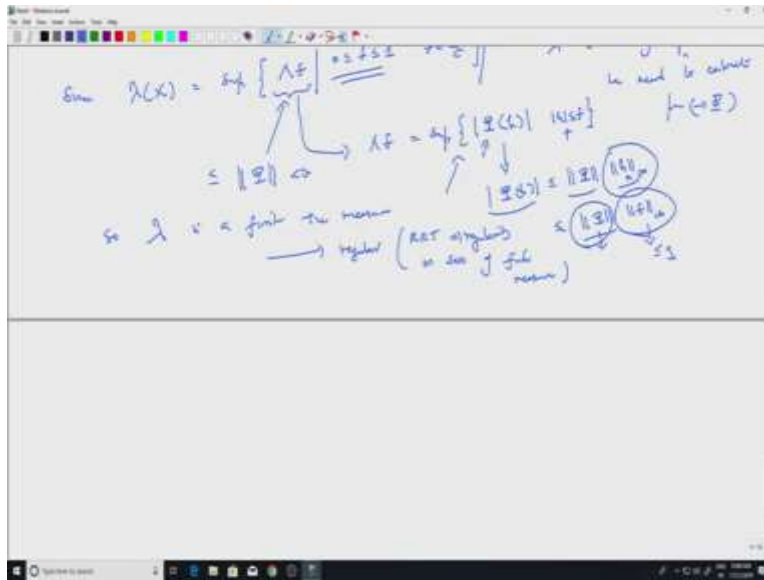

lambda F minus, right. Because lambda on F plus and lambda and F minus are defined, right, because they are positive functions in Cc plus x.

So, this makes sense, ofcourse, you have to show that it is linear, okay. So, let us, let me remind you how this is done and for and for complex valued functions. So, lambda of u plus iv is lambda u plus i times lambda v, right where u and v are real valued, real valued. So, how is lambda u defined? By this this formula, right. So, that gives me a formula for lambda of u plus iv which is an arbitrary function in Ccx, okay, in Ccx.

So, what I mean is if I take arbitrary g in Ccx, then g I can write as u plus iv. So, I define lambda of g to be lambda u plus i times lambda v, okay. What is lambda u? I write u as u plus minus u minus and V as v plus minus v minus and apply lambda to all of them. So, that gives me a definition. So, these are definitions, right, so the definition. With this definition you need to prove that it is linear, okay.

(Refer Slide Time: 06:46)

So, prove that, so, that is trivial prove that but it requires algebraic manipulation prove that lambda is linear okay in  $C_c$  or on  $C_c X$  by this definition, okay. So, let us let me remind you how this is done for real valued functions, real valued. So, let us take  $h$  equal to  $F$  plus  $g$ , okay,  $F, g, h$  are in  $C_c X$ . What does that mean?  $h$  plus minus  $h$  minus is equal to  $F$  plus minus  $F$  minus, plus  $g$  plus minus  $g$  minus, right, that is how you will write.

Now you bring all the positives, so, I want to write this is the equality of two positive functions. So I write this as  $h$  plus, plus  $F$  minus, plus  $g$  minus, right. So this term and this term went to the left hand side, and this is equal to  $F$  plus, plus  $g$  plus which is already on the right hand side and this term, I take it to the right hand side so  $h$  minus. But these are positive functions.

Now, on positive functions, you know lambda is linear. So, lambda  $h$  plus, plus lambda  $F$  minus, plus lambda  $g$  minus is equal to lambda  $F$  plus, plus lambda  $g$  plus, plus lambda  $h$  minus, right, because it is linear on both on positive function, and then you can rearrange to get that lambda of  $g$  is equal to lambda  $F$  plus lambda, right? That is what we did with integrals and that is precisely what is happening here as well, okay, and then you can extend it to complex valued functions, okay. So, let us let us continue.

So, lambda is linear in  $C_c X$  and lambda is a positive linear functional, positive linear function right, because that is how it was defined on the positive functions, right. So by Riesz representation theorem there exists a positive Borel measure lambda, small lambda such that

capital  $\lambda$   $\int F$  equal to integral over  $x$ . So, this is a positive Borel measure. So, there is no problem with defining the integrals it is true for every  $F$  in  $C_c(X)$ .

So, the  $\lambda$  we have got here is actually  $\int \mu$ , we need to extra  $\mu$ ,  $\mu$  is the measure we want, right, which defines the linear functional  $\phi$ , right. So, this will correspond to  $\phi$ , okay, and  $\int \mu$  which is  $\lambda$  corresponds to capital  $\lambda$  that is what is happening of course, you will notice this only after the proof is done, okay.

So, since  $\lambda$  of  $X$ , so this is the measure of the whole space  $\lambda(X) = \int 1$  equal to supremum over  $\lambda(F) \leq \int F \leq 1$  that is easy to see, for  $F$  in  $C_c(X)$  of course,  $C_c(X)$ . This is of course, so let us try to bound this.

So if I look at any such function here, so I have  $\lambda(F)$ , which is again a supremum, for supremum of  $\int \phi(h)$  of a  $\phi$  of let us say  $h$ , right,  $\int h \leq F$ , okay. Now, each of these quantities  $\int \phi(h)$ ,  $\int \phi(h)$ , remember  $\phi$  is a continuous linear functional. So, that is less than or equal to the norm of  $\phi$  times the norm of  $h$ , right, the supremum norm of  $h$ . So, we have seen this several times if I have a continuous linear functional this happens right.

So,  $\|\phi\|$  is the supremum over the unit ball, right. So, we have we have done this for  $L^p$  the same proof works here as well. So, any element here is bounded by  $\|\phi\| \int h$ . But what is  $\int h$ ? It is the supremum of  $\int h$ , but  $\int h \leq F$ , right so, I replace this by  $F$ . So, I have  $\|\phi\| \int F$  and  $\int F$ , okay.

So, any element here is less than or equal to  $\|\phi\| \int F$ , which is a constant times  $L^\infty$  norm of  $F$  or the supremum norm of  $F$ . So, that carries forward to any element here, right. So that will be less than or equal to whatever the quantity here times the  $L^\infty$  norm of  $F$ , but  $\int F$  is between 0 and 1. So, this would be less than or equal to 1. So inside here any element is less than or equal to just the norm  $\|\phi\|$ , right.

So this is less than equal to  $\|\phi\|$  which is finite because  $\phi$  is a continuous linear functional, right? So,  $\lambda$  is a finite measure.  $\lambda$  is a finite positive measure, right. That is what should happen right because  $\lambda$  we want it to be finally  $\int \mu$  so it better be the finite positive measure, okay. So, that is one point. Since it is a finite measure, it is also regular, right?

Because regularity, RRT gives you Riesz representation theorem implies a regularity on sets of finite measure, right.

But the whole space itself finite measure, so, every set has finite measure and so, all sets are regular. So, that is all regularities, okay. So, we are towards the end of the proof.

(Refer Slide Time: 13:15)

Now, if  $f \in C(X)$   $\rightarrow$   $\|f\|_\infty = \int |f| dx = \int |f| dx = \int |f| dx$   $\rightarrow$   $\|f\|_\infty = \int |f| dx$

$C(X) \subseteq L^1(X)$  is dense

$\exists$   $g \in L^1(X)$   $\rightarrow$   $\|g\|_1 \leq 1$   $\rightarrow$

$\Phi(f) = \int f g dx$   $\forall f \in C(X)$

def:  $\Phi = g dx$  then  $\Phi$  is complex measure

$\| \Phi \| \leq \|g\|_1$

$\forall f \in C(X)$   $\rightarrow$   $\| \Phi \| \leq \|g\|_1$

$\Phi(f) = \int f g dx$

$C_b$   $\rightarrow$   $\| \cdot \|_\infty$

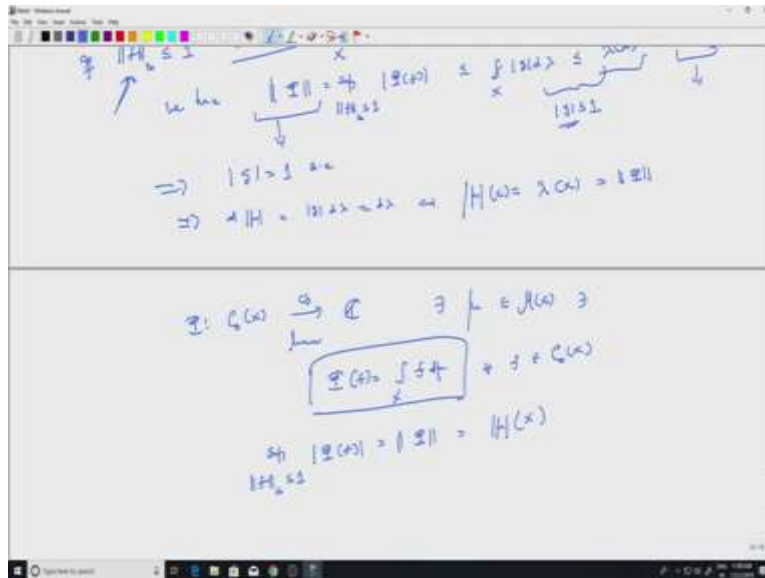

$C(X) \subseteq C_b$   $\rightarrow$   $\| \cdot \|_\infty$

$\| \Phi \|_\infty \leq \|g\|_1$

we have  $\| \Phi \|_\infty = \|g\|_1$

$\Rightarrow \| \Phi \|_\infty = \|g\|_1$

$\Rightarrow$

So, next, so now comes the tricky part really tricky part so you have to keep track of the norms and the spaces, okay. So, next if  $F$  is in  $C_c$  of  $X$ , this is fine there is no problem, mod  $\phi$  so,  $\phi$  remember is our original linear functional for which we want to find the measure  $\mu$ .

This ofcourse less than to  $\lambda$  mod  $F$  by definition itself, but  $\lambda$  is given by a small  $\lambda$  right the positive function, positive measure  $\lambda$ . But this is what we call  $L^1$  norm of  $F$ , okay, with respect to  $\lambda$ . So, now  $F$  is in  $C_c X$ , what this says is  $\phi$  is linear, right? So, it is a  $\phi$  is a continuous linear functional with respect to the  $L^1$  norm right on  $C_c X$  and  $C_c X$  is dense.

So,  $C_c X$  in  $L^1 \lambda$  is dense that we know, right, this is in general true and we have  $\phi$  defined like this, a continuous linear functional on  $C_c X$  with  $L^1 \lambda$  norm. So, the space you should remember very carefully, we are now viewing  $C_c X$  as a subset of  $L^1$  of  $\lambda$  not  $C_0$  right now, we are looking at  $L^1$ . So,  $\phi$  is a continuous linear functional on  $C_c X$  with  $L^1$  norm so it will extend to the whole space because it is dense, okay.

So extend, so  $\phi$  extends uniquely to continuous linear functional, continuous linear functional on  $L^1$  of  $\lambda$ , okay. But continuous linear functions on  $L^1$  of  $\lambda$  are given by  $L^\infty$  functions, right,  $L^\infty$  functions, okay. So, that means, there exists some  $g$  unique  $g$ , right, in  $L^\infty$  of  $\lambda$  such that well what do I know about  $L^\infty$  norm of  $g$ ? Ofcourse, this will have to be less than or equal to 1, okay.

So, let us see why because, on a dense subspace  $\phi$  of  $L^1$  norm of  $F$  is less than or equal to  $L^1$  norm of  $F$ , right. So, let me write down that again  $\phi$  of  $F$  is less than or equal to  $L^1$  norm of  $F$ . So, if I take supremum over  $F$   $L^1$  norm of  $F$  this is result to  $L^1$  norm of  $F$  but that is less than or equal to 1 right you are taking supremum over the unit ball so, that is less than equal to 1.

So, the  $g$  you get here will also have that property, right so, it will be less than or equal to 1. So, the only catch here is that  $\phi$  of  $F$  is less than this, this quantity, this inequality what we know is only for  $F$  in  $C(X)$ , okay. But it extends to  $L^1$  because of density and you can apply this. So the  $g$  you get will have the property that it is bound, okay.

So, there exists a  $g$  such that  $\phi$  of  $F$  equal to integral over  $X$   $F g d\lambda$ , right because that is how it will be defined for every  $F$  in  $L^1$ , okay. So, let us write this in a box. So, we are getting expressions for  $\phi$  now, right. So, at least in particular for  $C(X)$  I have this expression but I want it to be integral with respect to a measure, right. So, this guy we will call  $d\mu$ , okay. So, define  $d\mu$  to be  $g d\lambda$ .

So, you know what that means, now, we have done this couple of times, okay. So, that gives me a complex measure because  $g$  is in  $L^1$  is finite,  $g$  has more or less than to 1, so, it is an  $L^1$  function and so it is a complex measure, okay. So hence  $\mu$  is a complex Borel measure, okay, complex measure and  $\phi$  of  $F$  is equal to integral over  $X$   $F d\mu$  for  $F$  in well  $C(X)$  surely, but  $C(X)$ , okay.

So now comes the so tricky part, so  $\phi$  of  $f$ , now I can write as integral over  $X$   $F d\mu$  for  $F$  in  $C_0(X)$ . Well that is because  $C(X)$  is dense in  $C_0(X)$ , okay, with respect to the supremum norm, okay and this is a continuous, is continuous with respect to the supremum norm and this of course, we have seen whenever we have a complex measures this will be continuous with respect to supremum norm, okay.

So, there are several things here which you should understand in the earlier case we used  $L^1$  norm, right and this was a continuous linear functional with respect to  $L^1$  norm but initially defined on  $C(X)$  and so, you extend it to  $L^1$  and that gave me a function  $g$ , right, which gave me a measure. Now, if I go back so, instead of looking at  $L^1$  if I look at only  $C(X)$ , both sides will be continuous with respect to the  $L^\infty$  norm.

Which means they will extend to the completion of  $C_c(X)$  with respect to  $L^\infty$  norm which is  $C_0(X)$ , okay, so now I have this for all  $F$  in  $C_0(X)$  which is what we want, right, okay. So, that gives me a measure, so that is the measure in the Riesz representation theorem, but we have not completed because we have to (compete) compute the norm, okay.

So, if  $L^\infty$  norm of  $F$  is or the supremum norm is less than or equal to 1, modulus of  $\phi(F)$ , okay, this is of course less than or equal to  $\int |F| d\lambda$ , right. Because  $d\mu$  is, so remember  $d\mu$  is  $g d\lambda$ . This is of course less than or equal to  $\int |F| g d\lambda$ , because,  $L^\infty$  norm of  $F$  is less than or equal to 1. So I can pull that out I will get  $\int |F| g d\lambda$ , okay.

So, this from here we have the norm of the linear function itself which is the supremum over the unit ball so, let me write it once more  $\phi(F)$ . So, whenever norm is less than to 1, I know that  $\phi(F)$  less than to this. So, this is less than equal to  $\int |F| g d\lambda$ , okay, which is less than or equal to I know that  $\int g d\lambda$  is less than or equal to 1. So, this is less than to  $\lambda(X)$ , right because  $\int g d\lambda$  is less than or equal to 1, I pulled that out.

So, what did we do? Well we have okay, we have norm  $\phi$ , I have  $\lambda(X)$ , but recall that  $\lambda(X)$  was less than or equal to norm  $\phi$  that is how we proved that  $\lambda$  as a finite measure. So, let us see with somewhere here, okay. So,  $\lambda(X)$  the total measure was supremum of  $\int |F| g d\lambda$ ,  $F$  between 0 and 1  $F$  in  $C_c(X)$ , but each of them we proved that is less than to this constant.

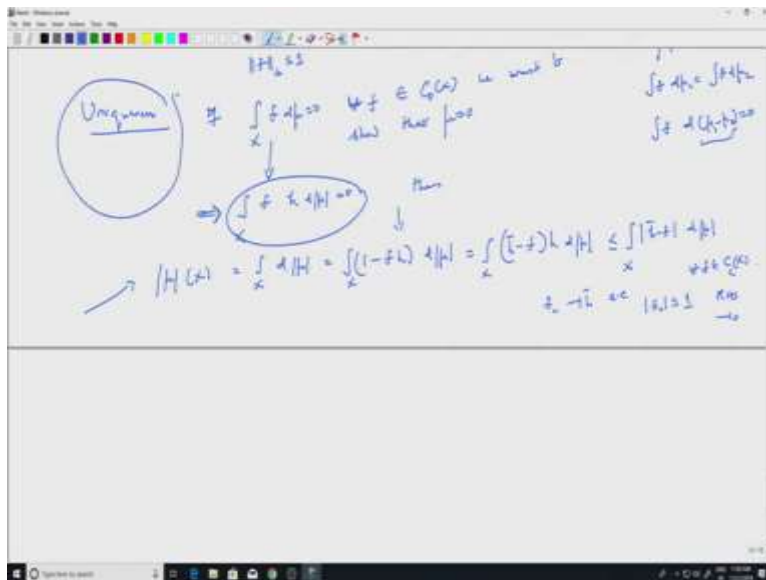

So the, that is how we proved that  $\lambda$  is a finite measure, right. So, we have this, this is less than equal to norm  $\phi$ . So, we started from here we ended up here and we have so all the inequalities or equalities which will also imply that instead of  $\int |F| g d\lambda$  less than or equal to 1 which will give the inequality here if it is equality the  $\int |F| g d\lambda$  will have to be equal to  $(\int |F| g d\lambda)$  (22:41).

So, this will imply  $\int |F| g d\lambda$  equal to 1 almost everywhere. So, now, if we go back to this thing you will see that  $\int |F| g d\lambda$  equal to 1 so, this is the polar decomposition for our representation for  $\mu$ , okay. So, we completed by writing  $D \mu$  equal to  $\int |F| g d\lambda$  equal to  $\int |F| g d\lambda$  because  $\int |F| g d\lambda$  is 1 almost everywhere and  $\int |F| g d\lambda$  of  $X$  equal to  $\lambda(X)$  and which is of course equal to norm because all these are equalities now, okay.

So, that is what we wanted to prove, right. So, let me write it in as a final line. So, if I take  $\phi$  which is a continuous linear functional on  $C_0(X)$ , right continuous linear, what did we do? We proved that there exists a Borel measure  $\mu$ , right, complex measure such that  $\phi(F) = \int F d\mu$ , right.

That is the main thing of course, this is true for every  $F$  in  $C_0(X)$ , but the additional fact is that the norms are equal okay. So, norms meaning the norm  $\|\phi\|$  which is the supremum of  $|\phi(F)|$  over the unit ball of  $C_0(X)$ , right, this is what we call the norm of  $\phi$ , okay. This is actually  $\|\mu\|$ ,  $\|\mu\|$  is the modulus of  $\mu$  which is the total variation positive measure of  $\mu$ . So, that is how you identify the continuous linear functions, okay. So, we will quickly finish off the uniqueness and then stop. So start with uniqueness.

(Refer Slide Time: 24:52)

So uniqueness of the measure  $\mu$ , okay, so if there are 2 suppose I have 2 measures  $\mu_1$  and  $\mu_2$ , then I am like writing the  $\mu_1$  is equal to integral  $F d\mu_2$ , right these are the linear functional which are equal. So, that is same as saying integral of  $F d\mu_1$  minus  $\mu_2$  is 0.

Because if  $\mu_1, \mu_2$  are complex measures,  $\mu_1$  minus  $\mu_2$  is a complex measure and you can integrate. So this is 0. So I want to say  $\mu_1$  minus  $\mu_2$  is 0 and  $\mu$  and so  $\mu$  is 0, right. So, if the  $\mu$  is 0, we want to show for every  $F$  in  $C_0(X)$ , we want show that  $\mu$  is 0 right that is the

uniqueness part, okay. So, from here, what do we have? We get  $\int x \, d\mu$  is 0, okay.

Then so, just 1 more line from here, then  $\int x \, d\mu$ . So, I want to say  $\int x \, d\mu$  which is same as saying  $\int x \, d\mu$ , this is equal to  $\int x \, d\mu$ , that is the definition, which is equal to  $\int x \, d\mu$ , okay. What did I do? I have added this extra term  $\int x \, d\mu$ , but  $\int x \, d\mu$  is 0, right? So I have just subtracted 0, so then nothing will change.

So this is equal to I can take  $h$  outside, so  $\int h \, d\mu$  because  $\int h \, d\mu$  is 1, so I, if I  $h$  it outside, I am going to get an  $\int h \, d\mu$  instead of 1, which is of course less than or equal to I take the modulus inside, so, modulus of  $\int h \, d\mu$  is  $\int h \, d\mu$ , okay. So,  $\int h \, d\mu$  is a nice function right in  $L^1$ , this is true for every  $F$  in let us say  $C_0$  but in particular  $C_c$ , right.

So, I can choose  $F_n$ 's converging to  $\int h \, d\mu$  almost everywhere and  $\int F_n \, d\mu$  less than or equal to 1 because  $\int h \, d\mu$  is less than or equal to 1, I will get that the right hand side goes to 0, so RHS goes to 0 which will tell me that  $\int h \, d\mu$  is 0, right. So  $\int h \, d\mu$  is 0,  $\mu$  is 0. So that is the uniqueness part, okay.

So, we stopped here. So, we proved the Riesz representation theorem in full, in the sense that if I look at that continuous linear functional on  $C_0$  of  $X$ , that is given via complex regular measure on  $X$ , so, that is what we did. This does not contain the Riesz representation theorem we stated earlier, okay. So, that is a long proof which we skipped that was for positive linear functional there was no continuity assumption, okay.

Once you have continued the assumption the measure you get will have to be finite because that is what will extend to  $C_0$  by taking the completion, okay, completion of  $C_c$  with respect to the supremum, okay. So, in the coming lectures we will look at some classical results, one is Lebesgue differentiation theorem. So, that would be a generalization of what you have seen in the real line as fundamental theorem of calculus or if I have a continuous function you integrate and differentiate you get back your continuous function.

And we will again look at some absolute continuity concepts, but in this case it would be about functions and I will relate it to absolute continuity of the measures which we have already, already seen and done, okay. So, we will stop here.
