Some properties of integrals over positive simple functions

Okay. So we defined integration for positive, measurable functions and we looked at some properties mono-tonicity things like that. We have to prove that the integral is linear in the sense that if I take two functions, positive, measurable functions, F and G, then the integral of F plus G is the integral of F plus integral of G and things like that. So if you notice the definition of the integration for simple functions, you will see that linearity is sort of built into it. But it is only for simple functions. From simple functions we will need to go to all positive functions by taking appropriate limits.

(Refer Slide Time: 1:16)

So that is what we will do. But first, let us start with a simple proposition. So I always have X script F and mu. X is a space, F is a Sigma algebra subsets of subsets of X, mu is a accountably additive measure Okay. So let X be a positive, measurable, simple function. So as of now, we are defining integrals only for simple functions and then positive functions. We will extend it to real valued and complex valued functions later.

So define, so we are taking one simple function s define mu of A to be integral over A Sd mu. So recall that we have defined integral over A Fd mu for any positive function to be equal to integral over X chi AF d mu right. So that, that makes sense. So this is a positive number

Okay. Can be zero, but it is a non-negative number. So for each A in script F, I am giving you a number okay. Then mu is a measure Okay. So this is how you can set new measures out of old measures. So if I have accountability additive measure mu, I can define another measure, using a positive function.

So let us prove this. This is very useful and we will use it in the next theorem. So to prove that, recall what is the measure? So to prove that mu is a measure. I need to show that two properties, mu phi zero and countable additivity right. Union Aj is summation mu Aj right. These are the joints sets. There are two things to done. So let us look at the first one. What is mu of empty set? Well this is integral over empty set as d mu. So remember this is zero because mu of the empty set is zero, right. This was one of the properties. So let us, let us go back and see that.

So if this set has measured zero, then the integral is zero. Whatever F is, does not matter. That is the property we have used here. Because this side has measure zero. So integral will be zero. So integrals over sets of measure zero is zero. Second property, so I take A1, A2, A3 etc. disjoint. Disjoint measurable sets in script F. And then I want to show that so to show that mu of union Aj equal to infinity equal to summation mu of Aj j equals to infinity. This is what we want to show to prove that this is a measure. So let us start with that. So remember s is a simple function, right.

(Refer Slide Time: 4:49)

To show that $\nu(\cup_{j=1}^{\infty} A_j) = \sum_{j=1}^{\infty} \nu(A_j)$

Assume that E_j are disjoint (w.l.o.g.)

$$s(x) = \sum_{j=1}^{\infty} \alpha_j X_{E_j}(x)$$

$$A = \cup_{j=1}^{\infty} A_j \quad \nu(A) = \int_A s d\mu = \int X_A \cdot s d\mu = \int X_A \cdot \left(\sum_{j=1}^{\infty} \alpha_j X_{E_j} \right) d\mu$$

$$= \int \left(\sum_{j=1}^{\infty} \alpha_j X_{A \cap E_j} \right) d\mu = \sum_{j=1}^{\infty} \alpha_j \int X_{A \cap E_j} d\mu$$

$$X_A \cdot X_{E_j} = X_{A \cap E_j}$$

So I can write it as, so let us write that. S is a simple function. So I can write S as $\sum_{j=1}^N \alpha_j \chi_{E_j}$ of X . I will assume that E_j are disjoint okay. I can always do that. This is without loss of generality. If they are not disjoint, you can make them disjoint. So if I look at A , so A is $\bigcup_{j=1}^{\infty} A_j$, j equal to 1 to infinity. I want to look at μ of A , what is μ of A ? This is $\int_A S d\mu$. This is the definition which by our definition, integral over the whole space.

Now I look at χ_A times $S d\mu$ okay. But as is our simple function, so I have χ_A times $\sum_{j=1}^N \alpha_j \chi_{E_j}$. Then this is how it looks like. Now it comes an important property of indicator functions. If I multiply χ_A with χ_{E_j} , this is nothing but $\chi_{A \cap E_j}$. Why is that? Remember χ_A takes values one and zero. χ_A is one if X is in A otherwise zero. So when I multiply, if I want to get one X should be in both the sets A and E_j . So it should be $A \cap E_j$. If it is outside A or outside E_j it is zero. So the product is zero. So that is simply the indicator function of $A \cap E_j$. So this tells me that this is equal to the integral over X $\sum_{j=1}^N \alpha_j \chi_{A \cap E_j} d\mu$. Now this is a simple function. I know how to integrate it. So this is simply $\sum_{j=1}^N \alpha_j \mu(A \cap E_j)$ Okay.

(Refer Slide Time: 7:24)

The image shows a handwritten derivation in a software window. The derivation is as follows:

$$\begin{aligned}
 \mu(A) &= \int_A 1 d\mu = \int \chi_A \cdot 1 d\mu = \int \chi_A \left(\sum_{k=1}^{\infty} \chi_{A_k} \right) d\mu \\
 &= \int \left(\sum_{k=1}^{\infty} \chi_{A_k} \right) d\mu = \sum_{k=1}^{\infty} \int \chi_{A_k} d\mu = \sum_{k=1}^{\infty} \mu(A_k) \\
 &= \sum_{k=1}^{\infty} \mu(A_k \cap E_j) = \sum_{k=1}^{\infty} \int \chi_{A_k} \chi_{E_j} d\mu = \sum_{k=1}^{\infty} \int \chi_{A_k \cap E_j} d\mu \\
 &= \sum_{k=1}^{\infty} \mu(A_k \cap E_j) = \sum_{k=1}^{\infty} \int \chi_{A_k} \chi_{E_j} d\mu = \sum_{k=1}^{\infty} \int \chi_{A_k \cap E_j} d\mu
 \end{aligned}$$

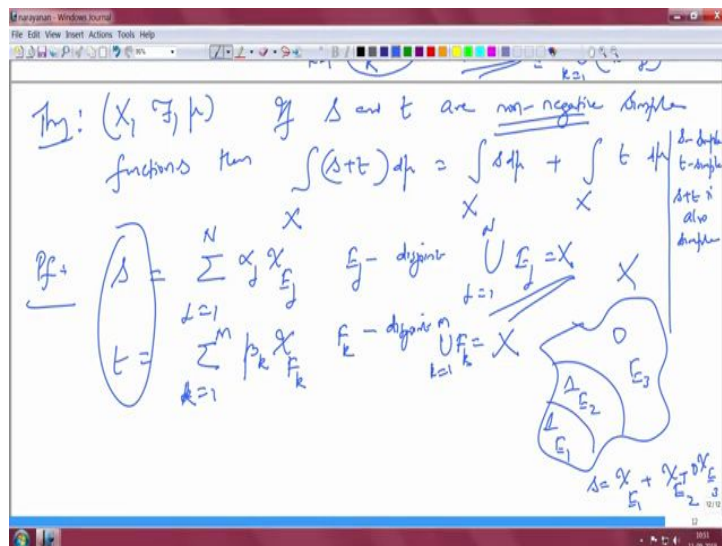

So we, we start from here. Start from the right hand side. This is equal to, so I am starting from here. This is equal to remember A is the disjoint union of A_k , right k equals one to infinity. So I can plug in that here. So this is simply $\bigcup_{k=1}^{\infty} A_k$, k equals one to infinity. But these are disjoint. like E_j are also disjoint Okay. So this is simply $\sum_{j=1}^N \alpha_j \mu(A \cap E_j)$ Okay.

Remember μ is countably additive measure and when I intersect, so let us, let us rewrite this. This is simply union K equal to one to infinity, A_k intersected with E_j , right that is how each term is so this is simply union of k equals one to infinity A_k intersection E_j . And this is a disjoint union, right. And μ of that would be the sum of things, right.

So μ have, that would be k equal one infinity μ of A_k intersected with E_j . So I have a finite sum here and infinite sum here. I can interchange. This is finite. So this is simply K equal to one to infinity, summation J equals one to N , μ of A_k intersection E_j which is equal to summation k equal to one to infinity. Well, what will be this? This is simply integral over X χ_{A_k} times summation J equal to 1 to N . I am sorry, there is an α_j missing. So there is an α_j here that is an α_j here. So $\alpha_j \mu(E_j)$, right indicator of E_j $d\mu$. Right, Exactly like this, exactly like the earliest step.

But, now I have A_k here and X here and degrading ends μ . So that is integral over A_k , right. That is a definition. K equal 1 to infinity integral over A_k , $S d\mu$, right. Remember this is my simple function S , but this by definition is the value of μ , μ of A_k . So I started with A is to be the, disjoint union and μ of A is equal to summation, μA_k . So that proves that μ as a measure. Great, so this is done. So this is why it does that countable additive measure okay.

(Refer Slide Time: 10:52)

So let us use this to prove linearity of integral. But as of now we will do it only for a simple functions okay. So let us write this as a theorem. So I have $X F \mu$ usual triple. X is a space,

\mathcal{F} is a Σ algebra of subsets of X , μ is countably additive measure okay. So if S and t are non negative simple functions then $\int_X (S + t) d\mu = \int_X S d\mu + \int_X t d\mu$. So remember, all those things are well-defined now. If S is simple, t simple function, then I know $S + t$ is also simple.

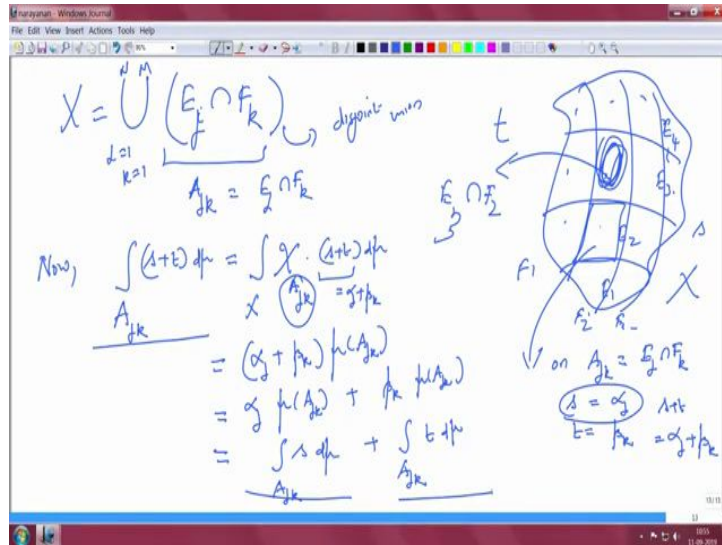

So the left hand side is well-defined. If I write this as $\sum_j \alpha_j \chi_{E_j}$, I know what the value on the left hand side is. Similarly, I know what the value is on the right hand side is. So this proves that it is linear for simple functions. Remember multiplying by a constant, if it is a positive content, because we are right now looking at only non- negative simple functions. If I multiply it was positive constant that comes out that we have already seen that was one of the properties we wrote down immediately after the definition of the integral.

So let us prove this. So we start with $S = \sum_{j=1}^N \alpha_j \chi_{E_j}$. So I will assume that E_j are disjoint. So remember that this we can always do. I can also assume that $\bigcup E_j$ is the whole space. Okay why is that? Well, so let us say this is my space X and let us say this is E_1 and this is E_2 . E_1 disjoint, right? So E_1 and E_2 and my simple function is $\chi_{E_1} + \chi_{E_2}$. There may be constants, but let us look at this example.

So here $E_1 \cup E_2$ is not the whole space, but I can always do $\chi_{E_1 \cup E_2} + 0 \chi_{E_3}$ compliment right. $E_1 \cup E_2$ let us call it E_3 , which is the compliment. So I will call it E_3 right. Well that is how it is, right. So if it is, it is one here, one here and E_3 does not exist. So the simple function is zero here. So if E_3 is not present in the expression for simple function, I can always multiply by zero and add χ_{E_3} . So that you know this I can always do. So that means there is probably a set where the simple function takes the value zero.

Similarly, I can let $t = \sum_{k=1}^M \beta_k \chi_{F_k}$, some other number β_k let us call it β_k χ_{F_k} okay. So F_k , so will write k here, F_k disjoint and $\bigcup F_k$, $k=1$ to M is the whole space. Now, I want to say that if I integrate $S + T$ these two, some of these two functions, sum of $S + T$, then I am going to get some of the integrals of $S + T$. So for that we will use earlier result okay.

(Refer Slide Time: 14:52)

So let us look at the picture again just to get some idea. So this is my space X and I have disjointified to get me E_1, E_2, E_3 and so $4, E_4$ let us say. That gives me a simple function S . But for simple function t , I may have a different disjointification right. So I will have F_1, F_2, F_3 and so on. So if I intersect both of them, so this would be intersection of let us say E_3 and F_2 right. So this is E_3 intersect with F_2 . So if I look at all such pieces that is a disjointification of X . So the whole X can be written as E_j intersection F_k right. Union J equal to one to N , K equal to one to M . That is all, and this is a disjoint union.

So let us call this A_{jk} . So I can write A_{jk} equal to E_j in the section F_k okay. Now integral, over A_{jk} of S plus t $d\mu$. Well, what does this, this I know by definition is indicator of A_{jk} you multiply that with s plus t $d\mu$ which is nothing but well, What is A_{jk} ? A_{jk} would be one piece like this, right on A_{jk} so remember A_{jk} is nothing but E_j in this section F_k . S takes the value. α_j , t takes the value β_k , right? That is how it is defined. So s plus t takes the value α_j plus β_k . So s plus t is the simple function, which takes the value α_j plus β_k in each A_{jk} . So this is equal to α_j plus β_k on A_{jk} .

So it is integral is nothing but α_j plus a β_k into the measure of A_{jk} , right. That is how the integral for simple functions is defined, which is nothing, but I can distribute this μ of A_{jk} plus β_k μ of A_{jk} which again by definition is simply integral, over A_{jk} α_j is simply the value of S on that set. So this is just s $d\mu$ plus integral over A_{jk} t $d\mu$, okay. So by disjointifying into smaller pieces, we have been able to prove that on A_{jk} we have linearity, right. Then we sum up, okay.

(Refer Slide Time: 18:30)

$$X = \bigcup_{j=1}^m \bigcup_{k=1}^n (E_j \cap F_k)$$
 disjoint union

$$A_{jk} = E_j \cap F_k$$

Now,
$$\int_{A_{jk}} (s+t) d\mu = \int_{A_{jk}} s d\mu + \int_{A_{jk}} t d\mu$$

$$\int_X (s+t) d\mu = \sum_{j,k} \int_{A_{jk}} (s+t) d\mu$$

$$= \sum_{j,k} \left(\int_{A_{jk}} s d\mu + \int_{A_{jk}} t d\mu \right)$$

$$= \sum_{j,k} \int_{A_{jk}} s d\mu + \sum_{j,k} \int_{A_{jk}} t d\mu$$

on $A_{jk} = E_j \cap F_k$

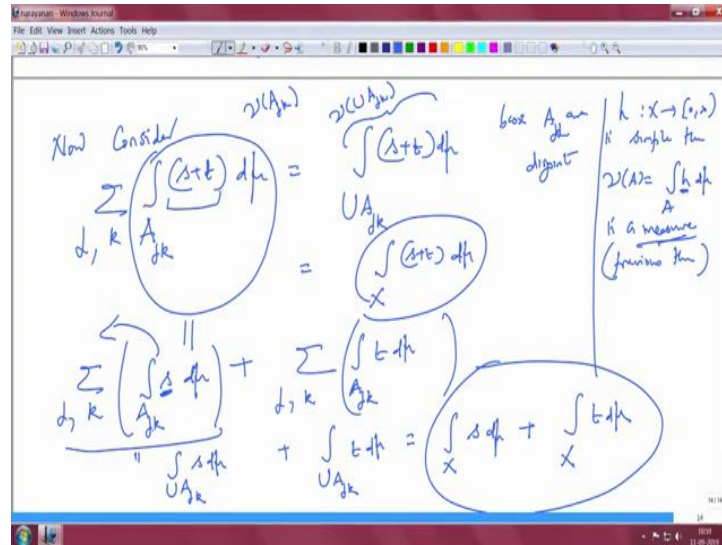

$$s = \alpha_j$$

$$t = \beta_k = \alpha_j + \beta_k$$

So let us see. So now consider summation i, j integral over okay, so maybe let us use J and K . J, K over A_{jk} of S plus $t d \mu$. Well, this is equal to recall the previous result. If I have a symbol function, if h from X to zero infinity is simple, then μ of a equal to integral over $A_h d \mu$ is a measure. This is what we proved previously, right. So this is the previous theorem. So we have a similar situation here, right. This is, consider this as my h . Then this is a measure, so I can think of this as new A_{jk} , right? But A_{jk} are disjoint.

So this would be integral over union, A_{jk} of, S plus $T d \mu$, Right. Why is that? Because A_{jk} are disjoint and μ as a measure, right. We use this. So it will be μ off Union A_{jk} , right? So this is nothing but μ of Union A_{jk} okay, well union A_{jk} the whole space, X , s plus $t d \mu$, right. Let us go back to A_{jk} and then we will see that. So these pieces are A_{jk} , right. And if I put together all of them, I will get the whole space X , okay. But let us look at, so this is, this is one end.

(Refer Slide Time: 20:37)

So let us look at LHS. So this is equal to, I know at the level of A_{jk} I have linearity, right. So if I integrate over A_{jk} , I know that it is the sum of two things. So these I can write as j , k integral over A_{jk} $s d\mu$ plus the summation J over k integral over A_{jk} $t d\mu$, right. This splits into two things and the summation splits it into two things, but now I can use the same property again use the same previous theorem that the integral is the measure.

So here this is like new or some other measure, right. With respect to the symbol function S so take h as S , then you see that this is a measure and A_{jk} are disjoint. So you are summing the measure of A_{jk} . So this will be equal to the integral of union A_{jk} $s d\mu$ plus integral union A_{jk} $t d\mu$, right which is same as union A_{jk} is the whole space $S d\mu$ plus integral $x t d\mu$.

Okay, so what we have proved is, this is equal to the sum of these things. So the integral is linear, then we are looking at a symbol functions okay.

So we conclude this lecture. Just to recall we started with positive measurable functions and well we initially define integration for positive simple functions. That was a natural extension of whatever we have seen for a step functions in the case of Riemann integration, but now we allow much more general sets. So that is how the simple functions came into existence and the integral of positive symbol functions were defined and using that for any positive measurable function, we can define the integral to be the supreme amount of the corresponding in the integral of simple functions, which are less than or equal to that

particular positive measurable function. And we saw some properties, monotonicity and how the positive constants come out. And now we have proved that it is linear with respect to symbol function. So if I take two positive symbol functions, add them and integrate that the same as this, some of the integrators of the positive of the individual, a symbol functions well we have to extend it to all positive functions but that will, that will be done in the classes in the future, okay.
