One dimensional heat equation-6

(Refer Slide Time: 0:48)

$$u_t = a^2 u_{xx}, \quad x \in (0, L), t > 0$$
$$u(x, 0) = g(x), \quad x \in (0, L)$$

Fourier method
Separation of variables: $u(x, t) = X(x)T(t)$ || non-trivial solns
 $X \neq 0, T \neq 0$

$$\frac{T'}{a^2 T} = \frac{X''}{X} = -\lambda^2, \quad \lambda > 0$$
$$\Rightarrow \underline{T(t) = c e^{-a^2 \lambda^2 t}}, \quad \underline{X(x) = c_1 \cos(\lambda x) + c_2 \sin(\lambda x)}$$

In this lecture we discuss the Fourier method to find the formula for the solution of the heat equation satisfying given boundary conditions. So again let me begin with the statement of the problem. So this is heat equation, so now we are working in a finite interval. So x is in, L is some positive number and t bigger than 0. So, initial condition is given, so before prescribing the boundary conditions at x equal to 0 and x equal to L .

So let us begin with the procedure for this Fourier method or separation of variables. So in this method the solution is sort in this form, namely $X x$, so this is what we did even while obtaining the solutions for the heat equation in the entire line, entire real line. This is what we started with, then you plug in this expression in the heat equation and you obtain T prime by a square T is equal to X prime by X and again as we discuss there this is the function of T only and this is a function of X only it must be constant.

And for physical reasoning we again take negative sign. Where lambda is positive and by the, so we are seeking non trivial solutions. So, that means these both the functions are not identically 0. But then this is just a 0 solution and it may not satisfy the initial condition. So whatever boundary condition we put at X equal to 0 and X equal to L they transform into boundary conditions for the function X.

So if you take positive sign again let me repeat that if you take positive sign that produces an exponentially growing T which is physically not acceptable. So we reject that the positive sign and take consider only negative sign. So in that case we immediately get the T of t some constant so let me write $c_1 e^{-\lambda^2 t}$. And for x we have so these will be the common features for all the boundary condition we consider and we have to only see which boundary conditions give us non trivial solutions that is important for us.

So for all the things this will be the common things only things is we have to determine the values of those lambda for which we get non trivial solutions. So this is certainly non trivial solution for T all the time. If we take c not equal to 0 but here since x has to satisfy appropriate boundary conditions the choose of c_1 , c_2 at least one of them non-zero is possible or not we have to see case by case.

(Refer Slide Time: 6:46)

zero Dirichlet bdry conditions:
 $u(0,t) = u(L,t) = 0 \quad \forall t > 0$
 $\Rightarrow X(0) = X(L) = 0$
 $X(0) = 0 \Rightarrow c_1 = 0$ and $X(x) = c_2 \sin(\lambda x)$
 $X(L) = 0 \Rightarrow c_2 \sin(\lambda L) = 0$
 For $c_2 \neq 0$, $\sin(\lambda L) = 0 \Rightarrow \lambda L = n\pi, n=1,2,\dots$
 Put $\lambda_n = \frac{n\pi}{L}, n=1,2,\dots$

$$u_t = a^2 u_{xx}, \quad x \in (0, L), t > 0$$

$$u(x, 0) = g(x), \quad x \in (0, L)$$

Fourier method
 Separation of variables: $u(x, t) = X(x)T(t)$ non-trivial solns
 $X \neq 0, T \neq 0$

$$\frac{T'}{a^2 T} = \frac{X''}{X} = \underline{\underline{-\lambda^2}}, \quad \lambda > 0$$

$$\Rightarrow \underline{\underline{T(t) = c e^{-a^2 \lambda^2 t}}}, \quad \underline{\underline{X(x) = c_1 \cos(\lambda x) + c_2 \sin(\lambda x)}}$$

So first we begin with simple boundary condition Dirichlet zero Dirichlet boundary condition namely $u(0, t) = u(L, t) = 0$ for all t positive. So let us begin with this boundary condition. And these two boundary conditions transform into the boundary condition for X so we get $X(0) = X(L) = 0$. So if you put so remember just let me write that $X(x) = c_1 \cos \lambda x + c_2 \sin \lambda x$ so if I put x equal to 0 \cos is 1 \sin is 0 that implies $c_1 = 0$.

So $X(0) = 0$ implies $c_1 = 0$ and then $X(x)$ becomes just $c_2 \sin \lambda x$ the other boundary condition namely $X(L) = 0$ implies $c_2 \sin \lambda L = 0$. So if you take $c_2 = 0$ then x is identically 0. We are not interested in the trivial solution. So for $c_2 \neq 0$ this $\sin \lambda L$ should be 0 and that implies so λL just $n\pi$ and if we cannot again take $\lambda = 0$ so this is $n = 1, 2, \text{ et cetera}$.

So in that case we obtain, so there is discrete set of λ so call it λ_n so put $\lambda_n = n\pi / L$. So this is general feature of the method, so this in order to find the non-trivial solutions the λ s will form only a discrete set and in this particular example we have seen that discrete set is given by $n\pi / L$.

(Refer Slide Time: 11:06)

$$T_n(t) = c_n \exp\left(-\frac{n^2 \pi^2 a^2 t}{L^2}\right), \quad X_n(x) = \sin\left(\frac{n\pi}{L}x\right)$$

We obtain
$$u(x,t) = \sum_{n=1}^{\infty} c_n \exp\left(-\frac{n^2 \pi^2 a^2 t}{L^2}\right) \sin\left(\frac{n\pi}{L}x\right)$$

We have
$$g(x) = u(x,0) = \sum_{n=1}^{\infty} c_n \sin\left(\frac{n\pi}{L}x\right)$$

And the corresponding solutions so write it so $T_n t$ some constant c_n exponential minus n square π square a square t by L square and $X_n X$ so since we are multiplying t and x so that constant will not right here so we will just write simply $\sin n \pi$ by $L x$. So again by linear superposition principle so we obtain a solution this is formally so just sum them $u x t$ is equal to summation n equal to 0 to infinity n equal 1 to infinity $n = 0$ c_n exponential let me write it again $\sin n \pi$ by $L x$.

So we need to determine these constants and constant will be determine by using the prescribed initial condition. So we have g of x is equal to $u x 0$ so simply substituting t equal to 0 in the infinite series where c_n . So this means the requirement on g is that it is expressed as a Fourier sin series which is convergent at all the points in that interval $0 < x < L$ and this is provided by the Dirichlet theorem in the theory of Fourier series.

(Refer Slide Time: 14:23)

If $g(0) = g(L) = 0$, & $g \in C^1$ except at a finite number of points, then

$$g(x) = \sum_{n=1}^{\infty} g_n \sin\left(\frac{n\pi}{L}x\right)$$

where $g_n = \frac{2}{L} \int_0^L g(x) \sin\left(\frac{n\pi}{L}x\right) dx$

We take $c_n = g_n$

So we take minimum requirement on g namely so if $g(0)$ is equal to $g(L)$ equal to 0 if g vanish at the end points and g is C^1 except at a finite number of points. Some more precisely you can take piece wise C^1 . So this Dirichlet theorem from the theory of Fourier series. So then g is expressed as Fourier sin series and the series is convergent to $g(x)$. so in general Fourier series you can always from that may not converse the function so there are some condition required.

And Dirichlet theorem provides these are sufficient conditions for the convergence of this infinite series sin series. Where g_n are the Fourier coefficient of g where $g_n = \frac{2}{L} \int_0^L g(x) \sin\left(\frac{n\pi}{L}x\right) dx$. So we take c_n equal to g_n and with this hypothesis on g then finally we obtain the solution.

(Refer Slide Time: 16:55)

Therefore, the solution is given by

$$u(x,t) = \sum_{n=1}^{\infty} g_n \exp\left(-\frac{n^2 \pi^2 a^2 t}{L^2}\right) \sin\left(\frac{n\pi x}{L}\right)$$

We need to show u_t , u_{xx} exist and are cont.
Term-by-term differentiation both w.r.t. x & t is possible for the following reason:

So therefore the solution is given by, I should not call it solution act, because we need to verify it is a solution. Solution is given by u of x t is summation n equal to 1 to infinity g_n exponential n square π square a square t by L square \sin n π by L x , where g_n s are the Fourier sin coefficients of the function g .

So with the stated hypothesis on g that is always possible, so we do get this infinite series involving sin function and exponential function. So what we still need to do is that u is, we need to show u is u_t u_{xx} exist and are continuous, so when u given by this infinite series the only way to check for the existence of these derivatives is again relying on the term by term differentiation and in this case this exponential term saves us.

So there is absolutely no difficulty in differentiating this infinite series term by term both with respect to t as well as with respect to x and the reason for that is, term by term differentiation both with respect to x and t is possible for the following reason. So let me write it separately.

So once we see in one particular case so if you just remember that so it smoothly goes through in other cases also. So look at these terms in the infinite series suppose I differentiate with respect to t I get an n square factor and if I differentiate with respect to x two times again I get an n square factor. So somehow that n square factor has to be tackled.

(Refer Slide Time: 21:15)

We have $n^k \exp\left(-\frac{n^2 \pi^2 t}{L^2}\right) \leq C_k$ for any $t > 0$

$\therefore u$ is the required soln of the stated problem

We can prescribe: $u(0,t) = u_1, u(L,t) = u_2$
This requires adding the term
 $\left(1 - \frac{x}{L}\right)u_1 + \frac{x}{L}u_2$
to the above solution u

Therefore, the solution is given by

$$u(x,t) = \sum_{n=1}^{\infty} g_n \exp\left(-\frac{n^2 \pi^2 t}{L^2}\right) \sin\left(\frac{n\pi}{L}x\right)$$

We need to show u_x, u_{xx} exist and are cont.
Term-by-term differentiation both w.r.t. x & t is possible for the following reason:

And in fact more generally we have n to the K exponential minus n square π square a square t . So you consider this sequence as n varies is bounded for any t . So whatever the terms come there term by term differentiation I can always make some big factor of n in the denominator so that the series converges and then you are justifying term by term differentiation both with respect to x and t so you simply do without any problem because of this observation.

And once we do term by term differentiation so we already seen that this is solution of the heat equation. So if you do one differentiation with respect to t one time and differentiation of this \sin term two times so each of this term satisfy heat equation so with this so there is absolutely no

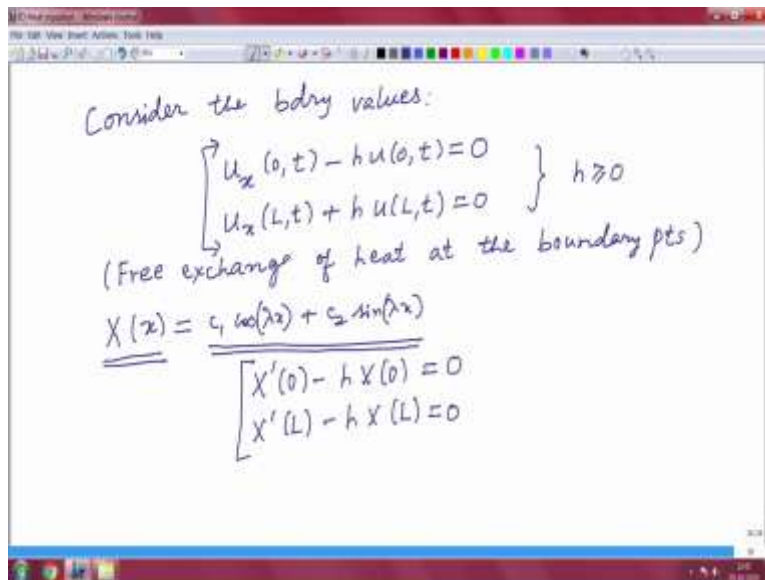

problem in doing term by term differentiation so therefore u is the require. So we already seen the uniqueness so this is the only solution of the problem required solution of the said problem stated problem. So this is a initial boundary value problem.

So we took the 0 directly boundary conditions here physically we say that the thin rod is insulated at both the ends. So this we can replace by some prescribed. So this is another so we can prescribe this is very simple with boundary conditions $u(0, t) = u_1$ $u(L, t) = u_2$. So u_1 and u_2 are constants that means the end points of the rod are maintained at some fixed temperature. So this is not the difficult problem at all

what you do is we already have the solution with 0 boundary conditions for that you just add one term this requires again by linearity. Linearity is very important this requires adding the term. So what term you add? So we add x equal to 0 I want it to be u_1 so you add $1/x$ by $L u_1$ and $L I$ want it to be u_2 so this is just x by $L u_2$.

So this function satisfies the boundary conditions and since it is only a function linear function of x so obviously its satisfy the heat equation. You just add this terms to the solution to the above solution u . And then you get the formula for the solution of this prescribed boundary conditions may be non-zero. So this is a simple observation.

(Refer Slide Time: 27:19)

So let us take one more, but in this case we will not explicit formula for the lambda n's, so consider the boundary conditions. And this now requires the Sturm–Liouville theory from

ordinary differential equations for the existence of solutions and the orthogonality conditions et cetera. So I will briefly discuss this one and may be provide some notes later.

So these boundary conditions u_x at 0 minus $h u$ at 0 equal to 0 and u_x at L plus $h u$ at L equal to 0 . So here h is a constant, non-negative constant, physically this is referred to as free exchange of heat at the end points. So this u_x that first derivative refers to the flow of heat across the boundary the points exchange of heat at the boundary points.

So now again recall this $X(x)$ is $c_1 \cos \lambda x + c_2 \sin \lambda x$. So these boundary conditions transform to boundary condition for x at 0 and L . So that means we have $X'(0) - h X(0) = 0$ and $X'(L) + h X(L) = 0$. Now you write down these two conditions in terms of c_1 and c_2 that require the algebra.

(Refer Slide Time: 30:37)

$$-hc_1 + \lambda c_2 = 0$$

$$(-\lambda \sin \lambda L + h \cos \lambda L)c_1 + (\lambda \cos \lambda L + h \sin \lambda L)c_2 = 0$$

Not both c_1, c_2 zero ($\because X \neq 0$)

\Rightarrow determinant $= 0$

This gives $2h \cos \lambda L = (\lambda - h^2) \sin \lambda L$

When $h > 0$, we can also there are infinitely $\lambda_n \rightarrow \infty$ satisfying the above eqn

$$T_n(t) = c_n \exp\left(-\frac{\lambda_n^2 t}{L}\right)$$

$$\Rightarrow X_n(x) = \cos(\lambda_n x) \sin(\lambda_n x)$$

So let me write that so you have minus $h c_1$ plus λc_2 equal to 0 and another one big expression minus $\lambda \sin \lambda L$ plus $h \cos \lambda L$ c_1 plus $\lambda \cos \lambda L$ plus $h \sin \lambda L$ c_2 is 0 . So we have got we have to determine c_1 is in c_2 and we have got two equations. What we want is not both c_1 c_2 zero. So this is requirement because we want X to be because X is not identically 0 .

And now we have two systems of two equations for c_1 and c_2 linear equation and if you want, so these are homogenous equations but we want c_1 c_2 to be none zero solution. So that implies the determinant of the coefficient matrix must be 0 , determinant of the coefficient matrix should be 0

in the system. And if you write down that so that this gives so you already seen some complication and these things are not explicit.

So $2h \cos \lambda L$ so you just compute the determinant and simplify it equate it to 0 and you get. So when h is 0 it is very simple so h is 0 this left hand side is not there though then again we get $\lambda \sin \lambda L$ equal to 0 and λ 's are easily given but h is positive we can only show there are infinitely many λ_n and they tend to infinity satisfying the above equation. So it is not possible to write down what exactly λ_n is but we can geometrically show.

There are infinitely many λ_n they are tending to infinity satisfying this equation and then again as usual now again this X_n and t_n is known but λ_n is not explicitly known t_n is again no problem. So you call it $c_n \exp(-\lambda_n^2 t)$ by L^2 may be π is missing. But X_n is again, now it will involve both cosine $\lambda_n x$ and $\sin \lambda_n x$ linear combination of both.

And now this time we cannot determine this λ_n explicitly, but we can still show that X_n 's are, X_n 's they form orthonormal family and any reasonable g can be written as Fourier series with respect to this X_n and finally we obtain a solution that requires little more computation and that will provide in the notes. How this λ_n 's can be obtain geometrically.

And though the formula is not explicit because of this λ_n 's but nevertheless the procedure is the same and we do obtain again the solution in the form an infinite series. Again there is no absolutely no problem with regard to verification of term by term differentiation both with respect to both t and x variables and we do obtain the solution of the stated boundary value problem. So with that we come to an end of this discussion on heat equation. So whatever is missing those things will be provided in the notes. Thank you.
