Lecture 39
One Dimensional Wave Equation

(Refer Slide Time: 0:38)

Welcome back. We will again now continue discussion on the Dirichlet problem which I started previous lecture, let me again just, so this is the Dirichlet problem we are trying to find the solution. So we have to find the value u_B and u_C , u_D is provided by the boundary conditions.

(Refer Slide Time: 1:14)

We have $D = (0, t - \frac{x}{c})$
 $(x < ct)$
 $B = (\frac{1}{2}(ct + x + x_0), \frac{1}{2c}(ct + x - x_0))$
 $C = (\frac{1}{2}(ct - x + x_0), \frac{1}{2c}(ct - x - x_0))$
(assume $x_0 < ct - x$)
Now $u(x) = h(t - \frac{x}{c})$

So we have, so let me write the coordinates of the point D, B, C. So D is nothing but, so it is on the boundary line, so that is x equal to 0 and its t variable is x by c . So here the characteristics are straight lines, so we have to just compute the intersection of two lines, so it is a little bit of work, but you do it. So that is no problem there, and, no this is not, let me just add in some notation here. That is D, D is, that is fine.

So then B, so this is the intersection of the characteristic passing through the point x_0 and the characteristic passing through the point x . So this is, we have to do some algebra here, I am skipping that algebra, plus x minus plus x_0 , 1 by $2c$, ct plus x minus x_0 . So we have to remember this, we have to remember x is less than ct , we are in that region.

So this t minus x by c is positive, so it is in the positive t axis and the point C is half ct minus x plus x_0 , $2c$, ct minus x minus x_0 . We want both this B and C in the region, in the first quadrant of the region, so the s coordinate and t coordinates obviously are positive. So for this reason, so this in order that this is positive, so we assume, so this is the small s , x_0 is at our disposal, x_0 is less than ct minus x .

And ct minus x is positive so I can always find an x_0 satisfying that condition. So there is no problem finding the x_0 , and soon we will see that x_0 does not appear in the final formula for the

solution, so it is just like a catalyst. So now u of D is simply h of t minus x by c , D the point on the boundary line, so there is no problem at all.

(Refer Slide Time: 6:18)

By D'Alembert's formula:

$$u(B) = \frac{1}{2} (u_0(ct+x) + u_0(x_0)) + \frac{1}{2c} \int_{x_0}^{ct+x} u_1(y) dy$$

$$u(C) = \frac{1}{2} (u_0(ct-x) + u_0(x_0)) + \frac{1}{2c} \int_{x_0}^{ct-x} u_1(y) dy$$

CPP $\Rightarrow u(x,t) = u(A) = u(D) + u(B) - u(C)$

We have $D = (0, t - \frac{x}{c})$

$x < ct$

$$B = (\frac{1}{2}(ct+x+x_0), \frac{1}{2c}(ct+x-x_0))$$

$$C = (\frac{1}{2}(ct-x+x_0), \frac{1}{2c}(ct-x-x_0))$$

(assume $x < ct-x$)

Now $u(D) = h(t - \frac{x}{c})$

(Refer Slide Time: 10:35)

$$\begin{aligned}
 \therefore u(x,t) &= h\left(t - \frac{x}{c}\right) + \frac{1}{2} \left(u_0(ct+x) + u_0(x_0) \right) \\
 &\quad + \frac{1}{2c} \int_{x_0}^{ct+x} u_1(y) dy - \frac{1}{2} \left(u_0(ct-x) + u_0(x_0) \right) \\
 &\quad - \frac{1}{2c} \int_{x_0}^{ct-x} u_1(y) dy \\
 &= h\left(t - \frac{x}{c}\right) + \frac{1}{2} \left(u_0(ct+x) - u_0(ct-x) \right) \\
 &\quad + \frac{1}{2c} \int_{ct-x}^{ct+x} u_1(y) dy \quad (x < ct)
 \end{aligned}$$

So therefore, u of x , t , u of D which is nothing but t minus x by C , plus u of B , so let us again recall that, u of B is here, half u_0 ct plus x plus u_0 , x_0 plus 1 by $2c$, x_0 to ct plus x , u_1 , y dy . So this term will be u of B minus half u_0 ct minus x plus u_0 , x_0 minus 1 by $2c$ x_0 to ct minus x , u_1 y dy . So let us simplify that, so that u_0 half u_0 x_0 there is minus half 0 u_0 x_0 , so x_0 we can choose any arbitrary point, so it does not influence the solution at all.

So this h of t minus x by c plus half u_0 ct plus x , now there is minus here, so u_0 ct minus x . And now we can combine these two integrals, so this is the integral from x_0 to ct minus x , this is from x_0 to ct plus x , so we can write this integral as x_0 to ct minus x and then ct minus x to ct plus x and one term cancels with this, so we have just 1 by $2c$ ct minus x ct plus x , u_1 y dy . So again, remember, let me stress that, so x is, this is in the region above the characteristic x equal to ct , so it is x less than ct . So let us combine both the formulas, so let us write in single formula.

(Refer Slide Time: 14:15)

$$u(x,t) = \begin{cases} \frac{1}{2}(u_0(x+ct) + u_0(x-ct)) + \frac{1}{2c} \int_{x-ct}^{x+ct} u_1(y) dy, & x > ct \\ \frac{h(t-\frac{x}{c}) + \frac{1}{2}(u_0(ct+x) - u_0(ct-x)) + \frac{1}{2c} \int_{ct-x}^{ct+x} u_1(y) dy, & x < ct \end{cases}$$

Solution on $x = ct$?

$$\lim_{\substack{(x,t) \rightarrow (ct) \\ y > ct \\ y < ct}} u(y,s) = \begin{cases} \frac{1}{2} u_0(2ct) + u_0(0) \\ + \frac{1}{2c} \int_0^{2ct} u_1(y) dy \\ \text{with } \frac{1}{2}(u_0(2ct) - u_0(0)) \\ + \frac{1}{2c} \int_0^{2ct} u_1(y) dy \end{cases}$$

So therefore, we have $u(x, t)$ depending on the position of the point, so in x bigger than ct is given by the D'Alembert's formula, so let me write that. This is for x bigger than ct . So when x is less than ct we obtain this one, so there is boundary thing coming, so let me write that separately, plus half $u_0(ct+x)$ minus $u_0(ct-x)$ that is plus 1 by $2c$.

So the expression for the solution is given separately for the regions x bigger than ct and x less than ct , so what about x equal to ct ? So that part still missing and before that, so we understand what is this x minus ct and x plus ct , but what is the ct minus x ? So let me just geometrically show where does that lie, when x is less than ct .

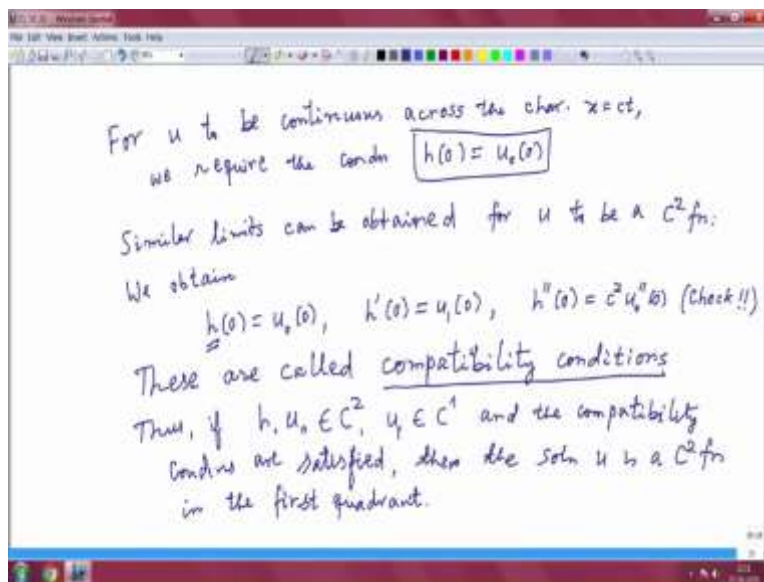

So again, just x equal to ct , so here is the point xt , so there is a characteristic meeting the boundary line x equal to 0 and then you draw the, so it is kind of reflected characteristics and this the point ct minus x_0 . And that is the reason it also appears with a negative sign here, so watch that one. So what about this solution on x equal to ct ?

So we can simply take limit of the solution, so we have found the solution in this region and this region, so we simply take limit from either side. So obviously we want solution to be c^2 and that imposes certain conditions on the boundary data and the initial conditions. So two expressions are here. So for example, let us compute the limit $u(x, t)$ as x approaches ct or in fact you can even do better, you can take y, s , y, s approaches ct, t , t is any positive number.

The only condition is that. So we are taking limit when y is bigger than cs , and y is less than cs , so we have to take two limits now. So you get when y is bigger than cs we are in this region, so when you take approach y, s to ct, t so this goes away, x is ct . So what you get is half $u_0, 2ct$ plus $u_0, 0$ plus 1 by $2c$ 0 to $2ct, u_1 y dy$. So if I use the first expression, that is what the limit I get and if I use the second expression, that is valid for y less than cs , that one.

So again, I get half $u_0 2ct$, we have to do it carefully, minus $u_0, 0$, plus 1 by $2c$ 0 to $2ct, u_1 y dy$. And there is of course boundary term, so that is coming h_0 . So I calculate this limit of the solution when the point approaches this line from above and from below, so I get two expressions. So in order that u is continuous so these should be equal and that gives us one condition.

(Refer Slide Time: 22:10)

So for u to be continuous across the characteristics, x equal to ct , we require the condition h_0 equal to $u_0(0)$. So similarly, you can work out the conditions for the solution to be C^1 and C^2 . So similarly, similar limits can be obtained for u to be a C^2 function. So this is the minimum thing we require, C^2 function. So let me write down, so it is a bit computation, so you can, so similarly you can differentiate this expression, differentiate this expression with respect either x or with respect to t and similarly u_{xx} , u_{xt} everything. So you will get two more conditions.

So we obtain, so this is bit work, so we have to do some computation, so let me write that first condition, h_0 is equal to $u_0(0)$. Then h_0' , just check whether, $u_1(0)$ and h_0'' is $c^2 u_0''$. Check. So these are called compatibility conditions. So these are required for the smoothness of the solution, these are called compatibility conditions. So that are required to satisfy between the boundary data and the initial conditions.

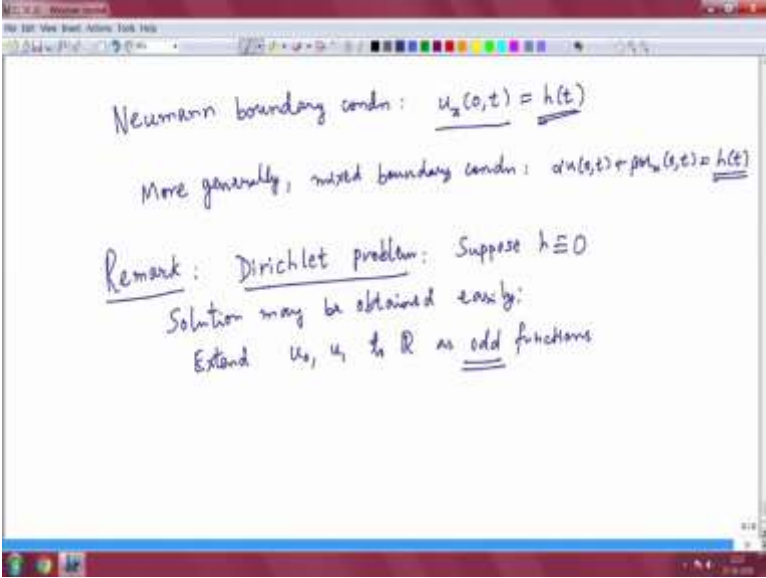

So this h_0 is boundary condition and u_0, u_1 are the, maybe there is c missing here, just check that, compatibility conditions. So thus if h_0, u_0 are C^2 functions and u_1 is a C^1 function in their respective domains and the compatibility conditions are satisfied, then the solution u is a C^2 in the first quadrant, that is important, and we have obtained a formula for that.

So in case any of the compat, here there are three conditions, any of the compatibility condition is not satisfied, then you will suffer that corresponding discontinuity either in the function itself or in the derivative across this characteristic. Again, just recall, so any discontinuity in the initial

condition, we saw that propagates along the characteristics, and similarly if the compatibility condition is not satisfied, any of them.

Then the solution will suffer that kind of discontinuity across that single characteristic namely x equal to ct . So this completes the solution of the Dirichlet problem.

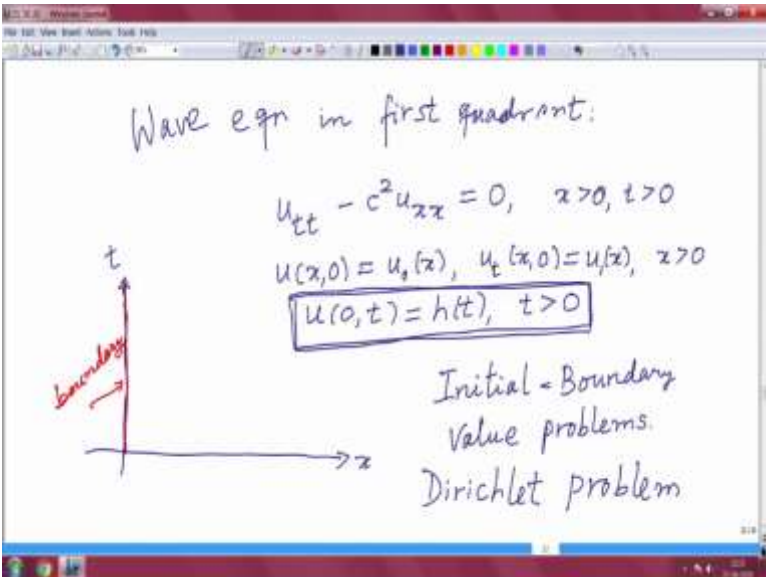

(Refer Slide Time: 30:00)

Neumann boundary condn: $u_x(0,t) = h(t)$

More generally, mixed boundary condn: $\alpha u_x(0,t) + \beta u(0,t) = h(t)$

Remark: Dirichlet problem: Suppose $h \equiv 0$
Solution may be obtained easily:
Extend u_0, u_1 to \mathbb{R} as odd functions

Wave eqn in first quadrant:

$$u_{tt} - c^2 u_{xx} = 0, \quad x > 0, t > 0$$
$$u(x,0) = u_0(x), \quad u_t(x,0) = u_1(x), \quad x > 0$$

$u(0,t) = h(t), \quad t > 0$

Initial-Boundary
Value problems.
Dirichlet problem

boundary →

t ↑

→ *x*

$$u(x,t) = \begin{cases} \frac{1}{2}(u_0(x+ct) + u_0(x-ct)) + \frac{1}{2c} \int_{x-ct}^{x+ct} u_1(y) dy, & x > ct \\ \frac{h(t-\frac{x}{c})}{2} + \frac{1}{2}(u_0(ct+x) - u_0(ct-x)) + \frac{1}{2c} \int_{ct-x}^{ct+x} u_1(y) dy, & x < ct \end{cases}$$

Solution on $x=ct$?

$$\lim_{(x_0) \rightarrow (ct)} u(y,s) = \begin{cases} \frac{1}{2} u_0(2ct) + u_0(ct) + \frac{1}{2c} \int_0^{2ct} u_1(y) dy & y > ct \\ \frac{1}{2} u_0(2ct) - u_0(ct) + \frac{1}{2c} \int_0^{2ct} u_1(y) dy & y < ct \end{cases}$$

So let me just mention, so another kind of Neumann boundary condition or even mixed conditions. So Neumann condition, instead of u you provide the data for the first derivative with respect to x and that is in this case is the normal derivative of u , normal to that line is in the x direction, so we are providing the first derivative.

And this is more difficult than the Dirichlet one, we will see that. And more generally, we can also give mixed boundary condition, more generally, mixed boundary condition, $\alpha u, 0, t$ plus $\beta u_x, 0, t$ equal to h_t . So these maybe different functions, I am just writing general things. So these are given functions.

So if α equal to 0 and β is not equal to 0, we get Neumann boundary condition and β equal to 0 and α not 0, we get Dirichlet boundary condition that we have already seen it and if both are non-0 then this is a mixed problem, we will see that. Just one remark, we will come to an end of this lecture, in the Dirichlet boundary value problem, Dirichlet problem, suppose the boundary data, suppose h is identically 0, so just let me show you that.

So I am taking this h identically 0, in that case there is a simple way of obtaining the formula by converting the problem into the entire line problem. In this case, so this is 0, solution formula, solution may be obtained easily, how we are doing that thing?

So extend u_0, u_1 , so u_0 and u_1 , they are defined only for x positive, so we extend to \mathbb{R} as odd functions and use these extended functions as the initial value for the wave equation in the entire

domain and then you apply the D'Alembert's formula and then you will get this, when h equal to 0 you precisely get just by solving the wave equation in the entire real line, h equal to 0.

So this you cannot do when h is not 0. So with that thing we will come to end of this class and in the next class we briefly study the Neumann boundary condition and see how the formula changes and that is a little more work, but we will do that so that you will get an idea how the formula changes. Thank you.
