Lecture-28
Heat Equation-4

(Refer Slide Time: 00:26)

The whiteboard shows the following derivation:

$$\begin{aligned} \chi(\rho) &= \frac{1}{4\rho^n} \iint_{E(\rho)} u(y,s) \frac{|y|^2}{s^2} dy ds \\ &= \frac{1}{4\rho^n} \iint_{E(\rho)} (u(y,s) - u(0,0)) \frac{|y|^2}{s^2} dy ds + u(0,0) \\ &\rightarrow u(0,0) \text{ as } \rho \rightarrow 0 \end{aligned}$$
$$\therefore u(0,0) = \frac{\chi(r)}{4} = \frac{1}{4r^n} \iint_{E(r)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

This completes the proof.

In the previous class we were discussing mean value property for the solution of heat equation. Let me again state that and we almost completed the proof.

(Refer Slide Time: 00:48)

\rightarrow Theorem (Mean Value Property) 3/15
 Let u satisfy the heat eqn $u_t = \Delta u$
 in a region $Q \subset \mathbb{R}^n \times \mathbb{R}$. Then, for $(x,t) \in Q$,

$$u(x,t) = \frac{1}{4r^n} \iint_{E(x,t;r)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

\downarrow average of u over E with some weight

for any $r > 0$ s.t. $E(x,t;r) \subset Q$.

So, here is the statement of this mean value theorem. So, if u is solution of the heat equation in a region in $\mathbb{R}^n \times \mathbb{R}$, then for all x, t in Q $u(x, t)$ is equal to this double integral. In fact it is $n + 1$ dimension integral and we discussed why it is called a mean value property because of this reason.

(Refer Slide Time: 01:23)

$$u(x,t) = \frac{1}{4r^n} \iint_{E(x,t;r)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

\downarrow average of u over E with some weight

for any $r > 0$ s.t. $E(x,t;r) \subset Q$.

\rightarrow Exercise $\frac{1}{4r^n} \iint_{E(x,t;r)} \frac{|y|^2}{s^2} dy ds = 1$
 $\hookrightarrow (n+1)$ dimnsl integral

Proof: Reduction:
 $K(x,t; y,s) = K(0,0; x-y, t-s)$

This integral = 1, so this weight is 1, so this $u(x, t)$ is the mean value of $u(y, s)$ over this $E(x, t, r)$ that is heat ball with this weight.

(Refer Slide Time: 01:48)

\rightarrow Exercise $\frac{1}{4r^n} \iint_{E(x,t;r)} \frac{|y|^2}{s^2} dy ds = 1$ 4/15
 $\hookrightarrow (n+1)$ dimensional integral

Proof: Reduction:
 $K(x,t; y,s) = K(0,0; x-y, t-s)$

May assume $x=0$ & $t=0$

Write $E(0,0;r) = E(r)$, $r > 0$

Need to prove:

So, I almost completed the proof just one last line.

(Refer Slide Time: 01:51)

Write $E(0,0;r) = E(r)$, $r > 0$ 4/15

Need to prove:

$$u(0,0) = \frac{1}{4r^n} \iint_{E(r)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

$(r > 0, E(r) \subset \mathbb{Q})$

$E(r): (y,s), s \in [-\frac{r^2}{4\pi}, 0]$

$\rightarrow |y|^2 \leq (-4s) \left[n \log r - \frac{n}{2} \log(-4\pi s) \right]$

And the proof started with first some reductions, so we can assume that $x = 0$ in \mathbb{R}^n and $t = 0$ in \mathbb{R} and that is just by translation and this integral does not change. So, we have to prove that $u(0,0)$ is equal to this integral.

(Refer Slide Time: 02:28)

$$\text{Let } \chi(r) = \frac{1}{r^n} \iint_{E(r)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

Put $y = r\xi, s = r^2\tau$
 $dy = r^n d\xi, ds = r^2 d\tau$
 $(y,s) \in E(r) \iff (\xi,\tau) \in E(1)$

$$\therefore \chi(r) = \iint_{E(1)} u(r\xi, r^2\tau) \frac{|\xi|^2}{\tau^2} d\xi d\tau$$

So, for that we just forget this factor 4 consider this function chi of r defined by this integral and we showed that chi is a constant function of r.

(Refer Slide Time: 02:45)

$$\therefore \chi(r) = \iint_{E(1)} u(r\xi, r^2\tau) \frac{|\xi|^2}{\tau^2} d\xi d\tau$$

$$\Rightarrow \frac{d\chi}{dr} = \iint_{E(1)} \left[\sum_{i=1}^n \frac{\partial u}{\partial \xi_i}(r\xi, r^2\tau) \xi_i + \frac{\partial u}{\partial \tau}(2r\tau) \right] \frac{|\xi|^2}{\tau^2} d\xi d\tau$$

$$= \frac{1}{r^{n+1}} \iint_{E(r)} \underbrace{\left(\sum_{i=1}^n \frac{\partial u}{\partial y_i}(y,s) y_i \right)}_A \frac{|y|^2}{s^2} dy ds$$

$$+ \frac{1}{r^{n+1}} \iint_{E(r)} 2 \frac{\partial u}{\partial s} \frac{|y|^2}{s} dy ds$$

So, that involves some computation.

(Refer Slide Time: 02:48)

$E(r)$

$$= \frac{-1}{r^{n+1}} \iint_{E(r)} \left(4n \frac{\partial u}{\partial s} \psi + \frac{2n}{s} \sum y_i \frac{\partial u}{\partial y_i} \right) dy ds - A$$

$\left(\frac{\partial u}{\partial s} = \Delta_y u \right)$
 $\Delta = \Delta_y$

$$\therefore \frac{dx}{dr} = A + B$$

$$= \frac{-1}{r^{n+1}} \iint_{E(r)} \left(4n \psi \Delta u + \frac{2n}{s} \sum y_i \frac{\partial u}{\partial y_i} \right) dy ds$$

integrate by parts w.r.t. u

And only in the last part of the proof we use that u satisfies the heat equation. So, this $\text{del } u$ by $\text{del } s$ is replaced by Laplacian u .

(Refer Slide Time: 03:09)

$$= A + B$$

$E(r)$
 B

Let $\psi(y, s) = \frac{|y|^2}{4s} - \frac{n}{2} \log(-4\pi s) + n \log r$

$\psi = 0$ on $\partial E(r) = \{(y, s) : K(y, s) = \frac{1}{r^n}\}$

Observe: $\frac{\partial \psi}{\partial y_i} = \frac{2y_i}{4s} \Rightarrow \sum \frac{\partial \psi}{\partial y_i} y_i = \frac{1}{2} \frac{|y|^2}{s}$

$$\therefore B = \frac{2}{r^{n+1}} \iint_{E(r)} \frac{\partial u}{\partial s}(y, s) \frac{|y|^2}{s} dy ds$$

And proof mainly relied on divergence theorem and this important function coming from the nature of the set a heat ball $E(x, t, r)$.

(Refer Slide Time: 03:27)

$$\therefore \chi(r) = \text{constant} = \chi(0)$$

Consider $\chi(r) = \lim_{\rho \rightarrow 0} \chi(\rho)$

$$\frac{\chi(\rho)}{4} = \frac{1}{4\rho^n} \iint_{E(\rho)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

$$= \frac{1}{4\rho^n} \iint_{E(\rho)} (u(y,s) - u(0,0)) \frac{|y|^2}{s^2} dy ds$$

So, once we know that chi is a constant function, so this chi of r = limit chi rho 0 tends to 0.

(Refer Slide Time: 03:35)

$$\text{Consider } \chi(r) = \lim_{\rho \rightarrow 0} \chi(\rho)$$

$$\frac{\chi(\rho)}{4} = \frac{1}{4\rho^n} \iint_{E(\rho)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

$$= \frac{1}{4\rho^n} \iint_{E(\rho)} (u(y,s) - u(0,0)) \frac{|y|^2}{s^2} dy ds$$

$$+ u(0,0)$$

$$\rightarrow u(0,0) \text{ as } \rho \rightarrow 0$$

$$\therefore u(0,0) = \frac{\chi(0)}{4} = \frac{1}{4r^n} \iint_{E(r)} u(y,s) \frac{|y|^2}{s^2} dy ds$$

But then we can write this chi rho by 4 = 1 by 4 to the n this integral over E rho and then you add and subtract this u 0, 0 and because of that integral is 1, so this is just 1. And by continuity of u the first integral goes to 0 as rho tends to 0, so we are just left with u 0, 0 and that is what we wanted to prove.

(Refer Slide Time: 04:09)

Heat ball : $E(x, t; r)$
 $x \in \mathbb{R}^n, t \in \mathbb{R}, r > 0$
 $E(x, t; r) = \left\{ (y, s) \in \mathbb{R}^n \times \mathbb{R} : s \leq t \text{ \& } K(x, t; y, s) \geq \frac{1}{r^n} \right\}$
 If $(y, s) \in E(x, t; r) \Leftrightarrow$
 $s \in [t - \frac{r^2}{4\pi}, t]$
 $\& \quad |x - y|^2 \leq 4(t - s) \left[\log \frac{\sqrt{4\pi}}{r} + \right]$

So, again let me just recall this heat ball $E(x, t, r)$. So, x is in \mathbb{R}^n , t is a real number and r is a positive real number. So, if what is $E(x, t, r)$? So, let me just again recall that, so this is set of all (y, s) in \mathbb{R}^n cross \mathbb{R} such that s is less than or equal to t and this is the heat kernel, so $K(x, t, y, s)$ bigger than or equal to $\frac{1}{r^n}$. So, if (y, s) belongs to $E(x, t, r)$, so using the expression for the heat kernel we saw that this is equivalent to, so s lies in the closed interval $t - r^2$ by 4π to t .

And then y it lies in the ball and $|x - y|^2$, so y lies in the ball with centre x and radius square is given by this number $\log \sqrt{4\pi}$, you can check that, this is oh some end is missing, so let me somehow is missing, so it is here only, let me just go there and stop rewriting it, it is here.

(Refer Slide Time: 08:20)

$$(r > 0, E(r) \subset \mathbb{Q})$$

$$E(r) = (y, s), \quad s \in \left[-\frac{r^2}{4\pi}, 0\right]$$

$$\rightarrow |y|^2 \leq (-4s) \left[n \log r - \frac{n}{2} \log(-4\pi s) \right]$$

$$\text{Let } \chi(r) = \frac{1}{r^n} \iint_{E(r)} u(y, s) \frac{|y|^2}{s^2} dy ds$$

$$\text{Put } y = r\xi, \quad s = r^2\tau$$

$$dy = r^n d\xi, \quad ds = r^2 d\tau$$

So, this is for 0 otherwise you will get x - y square and so here I have taken this x = 0 and t = 0 but that just translates.

(Refer Slide Time: 08:55)

$$E(x, t; r) = \{(y, s) \in \mathbb{R} \times \mathbb{R} : s \leq t \text{ and } |x - y|^2 \leq \frac{r^2}{4\pi} - s\}$$

$$\text{If } (y, s) \in E(x, t; r) \Leftrightarrow$$

$$s \in \left[t - \frac{r^2}{4\pi}, t\right]$$

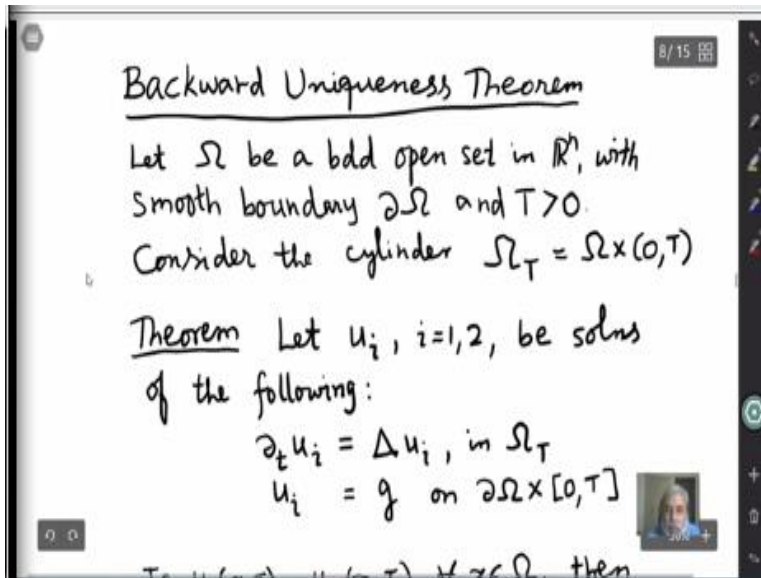

$$\& \quad |x - y|^2 \leq 4(t - s) \left[n \log r + \left(-\frac{n}{2}\right) \log 4\pi(t - s) \right]$$

$$\Rightarrow \text{not difficult to evaluate}$$

$$\frac{1}{4r^n} \iint_{E(x, t; r)} \frac{|y|^2}{s^2} dy ds$$

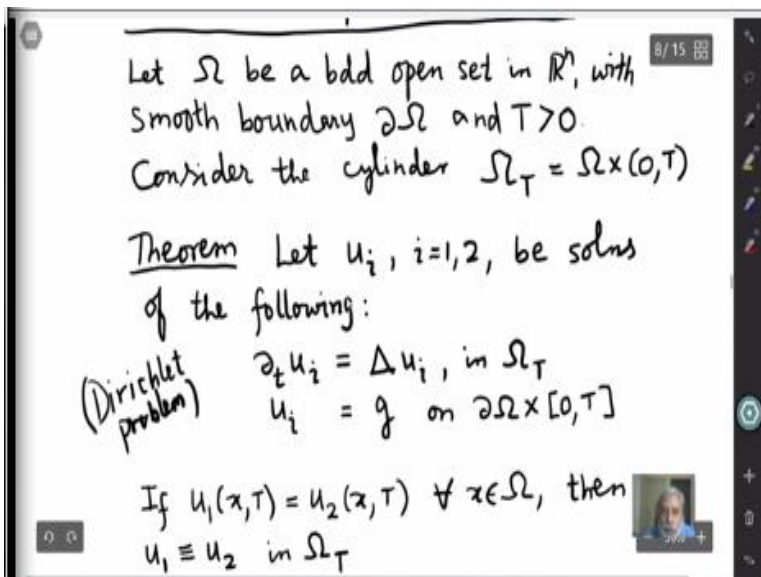

So, this is $n \log r + -$ let me write it here n by $2 \log 4 \pi t - s$. So, using this domains for s and y , so it then easy to, so not difficult to evaluate, if this integral 1 by 4 into r with n which is $n + 1$ dimensional integral mod y square + S square dy by ds . So, since the integrand is, now negative we can integrate as an iterated integral. So, first one integrates with respect to y using this bound and then you integrate with respect to S . And even integration with respect to y , so since this is a radial function, so we can use spherical coordinates.

(Refer Slide Time: 11:43)

So, with this we move to another interesting property of the solution of the heat equation and this is referred to as backward uniqueness theorem. So, let me first take the theorem and then I will remark on its interesting properties. So, again let Ω be a bounded open set in \mathbb{R}^n with smooth boundary $\partial\Omega$ and t is any positive number and consider this cylinder. So, this smooth boundary is required just because we want to integrate the parts and the divergence theorem should be valid, only for that reason we are assuming that smooth boundary.

(Refer Slide Time: 12:35)

Let u_1 and u_2 be the solutions of the following heat equations, so $\partial_t u_i = \text{Laplacian } u_i$ in Ω and $u_i = g$ on $\partial\Omega \times [0, T]$. So, this is a Dirichlet boundary value problem. So, the

important thing here is both u_1 and u_2 satisfy the same boundary condition g , so g is not changed.

(Refer Slide Time: 13:19)

(Dirichlet problem) $\partial_t u_i = \Delta u_i, \text{ in } \Omega_T$
 $u_i = g \text{ on } \partial\Omega \times [0, T]$

If $u_1(x, T) = u_2(x, T) \forall x \in \Omega$, then
 $u_1 \equiv u_2 \text{ in } \Omega_T$

- No assumptions on the initial conditions are made
- No assumption on growth of u_i is made.

Proof: Uses energy method

Then the statement of the theorem is if $u_1(x, T) = u_2(x, T)$ for all x in Ω then u_1 is identically equal to u_2 in Ω_T . So, that is why it is called uniqueness theorem, it is backward because at a positive time the condition is given, so namely that u_1 and u_2 are equal. And the conclusion is that u_1 and u_2 remain same for all T less than T . So, the importance of this theorem is that no assumptions on the initial conditions on u_1 and u_2 are made in the statement of the theorem.

So, there is no statement regarding the initial conditions on u_1 and u_2 . And we have already seen for the initial value problem to obtain a uniqueness result we have to make some growth assumptions on the solution. And in this theorem no such assumption on the growth of u_1 and u_2 is made. And yet this uniqueness statement is made in the results, so that is why it is interesting and also important with all site minimal data we are claiming the uniqueness of the problem.

(Refer Slide Time: 15:09)

8/15

Proof: Uses energy method

Put $u = u_1 - u_2$. Then, $u_t = \Delta u$ in Ω_T
 $u = 0$ on $\partial\Omega \times [0, T]$

Let $E(t) = \int_{\Omega} u^2(x, t) dx$

If $E(T) = 0$, suffices to prove $E(t) = 0 \forall t < T$

So, the proof uses energy method and this energy method we also use in wave equations. And this heat equation also enjoys some energies, energy estimate we can derive on them. So, for some again reduction since the problem is linear, so linear equation and linear boundary condition, so put $u = u_1 - u_2$ then u satisfy the heat equation in Ω_T . And since g is same so $u = 0$ on the boundary $\partial\Omega \times [0, T]$, this is the boundary of the cylinder.

(Refer Slide Time: 16:02)

9/15

$$\frac{dE}{dt} = 2 \int_{\Omega} u u_t dx = 2 \int_{\Omega} u \Delta u dx$$

$$= -2 \int_{\Omega} |\nabla u|^2 dx \quad (i)$$

$$\frac{d^2 E}{dt^2} = -4 \int_{\Omega} \nabla u \cdot \nabla u_t dx$$

$$= 4 \int_{\Omega} u_t \Delta u dx = 4 \int_{\Omega} (\Delta u)^2 dx$$

And here comes the energy, so E is the energy, so put E of $T = \int_{\Omega} u^2(x, t) dx$. So, you integrate only with respect to x , so this is a function of T alone. So, and this represents the total amount of heat at time t that is in the domain Ω . And now we are given that E of t

0, if you see the hypothesis $u = 0$ at $t = T$, that is given to us.

And we need to prove that $E(t) = 0$ for all t less than T . Because then this integral is positive, so if we prove that this is 0 then this is 0 everywhere and now we proceed to do that. And now we use this energy and so that is a function of t alone, so you differentiate with respect to t . So, just see how the energy varies with t and this very simple thing, so this you get $2 \int u_t \Delta u$ and u satisfy the heat equation.

So, u_t is replaced by Laplacian u and then u integrates by parts, so you get $-2 \int \Omega \text{grad } u \cdot \text{grad } u \, dx$. And there are no boundary condition as $u = 0$ on the boundary of the cylinder, there are no boundary conditions. So, we differentiate one more time, so second derivative of E with respect to t $\frac{d^2 E}{dt^2}$ and again you use the last expression, so you get another 2 there, so $-4 \int \Omega \text{grad } u \cdot \text{grad } u \, dx$.

(Refer Slide Time: 18:24)

Now

$$\frac{dE}{dt} = 2 \int_{\Omega} u \Delta u \, dx$$

$$\Rightarrow \left(\frac{dE}{dt} \right)^2 = 4 \left(\int_{\Omega} u \Delta u \, dx \right)^2$$

$$\leq 4 \left(\int_{\Omega} u^2 \, dx \right) \left(\int_{\Omega} (\Delta u)^2 \, dx \right)$$

$$= E(t) \frac{d^2 E}{dt^2}$$

And again integrate by parts, so you get $2 \int \Omega \text{grad } u \cdot \text{grad } u \, dx$. And again there are no boundary condition as u is 0. And now again you replace u_t by Laplacian u because u satisfy the heat equation, so we will get finally $4 \int \Omega \text{grad } u \cdot \text{grad } u \, dx$. And now we compare this the first derivative of the energy with the second derivative, so some simple

estimate. So, dE by dt is I am just using this expression dE by $dt = 2 \int_{\Omega} u \Delta u$ and when I take square on both sides, so I get 4 this integral whole square.

(Refer Slide Time: 19:29)

$$|dE/dt| \leq 4 \left(\int_{\Omega} u^2 dx \right) \left(\int_{\Omega} (\Delta u)^2 dx \right)$$

$$= E(t) \frac{d^2 E}{dt^2}$$

Suppose, on the contrary, $E(t) > 0$ for some $t < T$

$\exists [t_1, t_2] \subset [0, T]$ such that $E(t) > 0$ for $t \in [t_1, t_2]$ & $E(t_2) = 0$

And here I use (19:31) inequality and this integral is less than or equal to integral u square dx to the half but there is a 2 there, so it becomes 1 and similarly that 1. And now this first integral is nothing but the energy integral, so $E(t)$ is just integral u square dx . So, if I take this 4 inside here then that is precisely $d^2 E$ by dt^2 . So, we have this dE by dt whole square is less than or equal to $E(t)$ into $d^2 E$ by dt^2 .

And now to complete the proof we assume on the contrary that $E(t)$ is positive for E is always non negative, so E is positive for some $t < T$. So, we will get a contradiction with that assumption and then by continuity so we try to find the first $t < T$ with this property and that just by continuity there exists a sub interval t_1, t_2 in $[0, T]$. So, t_2 could be T such that $E(t)$ is positive for all t in this semi open interval t_1 to t_2 and $E(t_2) = 0$. So, this t_2 can be t itself that is given to us, so $E(T) = 0$, so certainly there is one such thing.

(Refer Slide Time: 21:31)

10/15

For $t \in [t_1, t_2)$, put $F(t) = \log E(t)$.

Then,
$$\frac{d^2 F}{dt^2} = \frac{E(t) \frac{d^2 E}{dt^2} - \left(\frac{dE}{dt}\right)^2}{E(t)^2} \geq 0$$

Thus, F is a convex fn.

For any $t \in [t_1, t_2)$ and $0 \leq \alpha \leq 1$,
 we have $F(\alpha t_1 + (1-\alpha)t) \leq \alpha F(t_1) + (1-\alpha)F(t)$

$\Rightarrow E(\alpha t_1 + (1-\alpha)t) \leq E(t_1)^\alpha E(t)^{1-\alpha}$

And now since $E(t)$ is positive in this interval, we can take logarithm. So, for t in this semi open interval put $F(t) = \log E(t)$ and now we want to convert this second derivative of F , the second derivative of $E(t)$ and that simple calculation yields us $\frac{d^2 F}{dt^2}$ is equal to, so there is numerator and denominator, denominator is $E(t)^2$ and numerator is $E(t) \frac{d^2 E}{dt^2} - \left(\frac{dE}{dt}\right)^2$.

And that is non negative by the estimate we obtained for $\frac{dE}{dt}$. So, F is a function of one variable such that its second derivative is non negative in this interval. And that is equivalent to F being a convex function. So, then this because of this condition on the second derivative F is a convex function.

(Refer Slide Time: 22:50)

For any $t \in [t_1, t_2)$ and $0 \leq \alpha \leq 1$,
 we have $F(\alpha t_1 + (1-\alpha)t) \leq \alpha F(t_1) + (1-\alpha)F(t)$
 $\Rightarrow E(\alpha t_1 + (1-\alpha)t) \leq E(t_1)^\alpha E(t)^{1-\alpha}$
 Let $t \rightarrow t_2 \Rightarrow \text{rhs} = 0$
 $\Rightarrow E(t) = 0 \quad \forall t \in [t_1, t_2) \quad \times$
 This completes the proof

And by the definition of the convex function we have that for any t in this semi open interval and any α between 0 and 1, we have F of $\alpha t_1 + 1 - \alpha t$ less than or equal to $\alpha F t_1 + 1 - \alpha F$ of t . And if we translate again back to the energy function E of t , so we have to take exponentials, so we take the exponential both sides and that yields this inequality for the energy. So, E of $\alpha t_1 + 1 - \alpha t$ is less than or equal to E of t_1 to the α E of t to the $1 - \alpha$ and this is true for all t in this semi open interval.

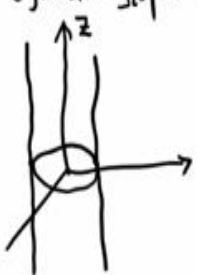

And now on the right hand side you just let t to t_2 , let t goes to t_2 and right hand side gives us 0 and that means we have that E of $t = 0$ for all t in this t_1, t_2 in that semi open interval. And that is a contradiction to our assumption, we have assumed that $E t$ is strictly positive in this semi open interval and that contradiction completes the proof. So, these are the some interesting qualitative properties of the heat equation that is fun.

(Refer Slide Time: 24:52)

Example : Mixed problem 10/15

Physical situation : 3D

circular cylinder: $\Omega = \{x^2 + y^2 \leq a^2, z \in \mathbb{R}\}$

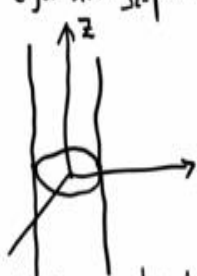

And next we discuss one example again regarding heat equations for this. Example, so let me state the problem and we will discuss the details perhaps in the next class. So, this is a mixed problem, so this is the physical situation, so we have a circular cylinder in three dimensional, 3D circular cylinder. So, $x^2 + y^2 \leq a^2$ and $z \in \mathbb{R}$. So, ideal situation, so this is the z direction, so we have this so infinite slope. So, this is (Ω) (26:59) ω .

(Refer Slide Time: 27:05)

Physical situation : 3D 10/15

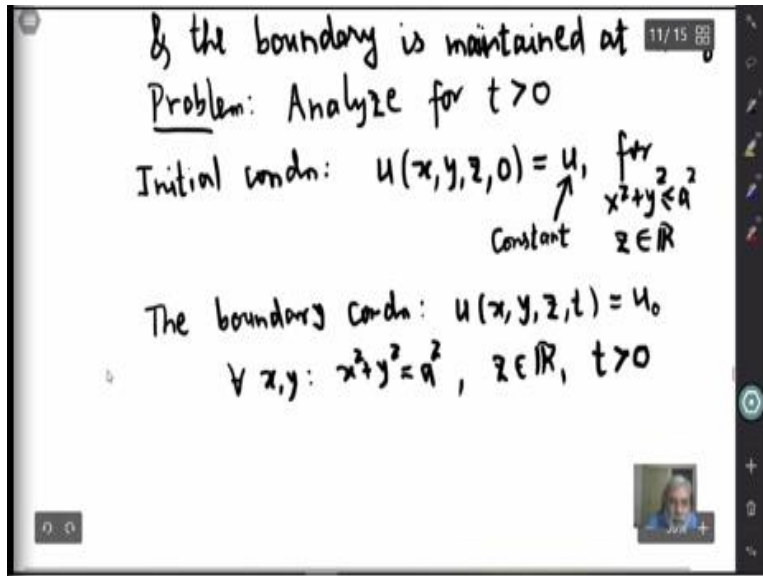

circular cylinder: $\Omega = \{x^2 + y^2 \leq a^2, z \in \mathbb{R}\}$

At $t=0$, cylinder is heated: $u = u_1$

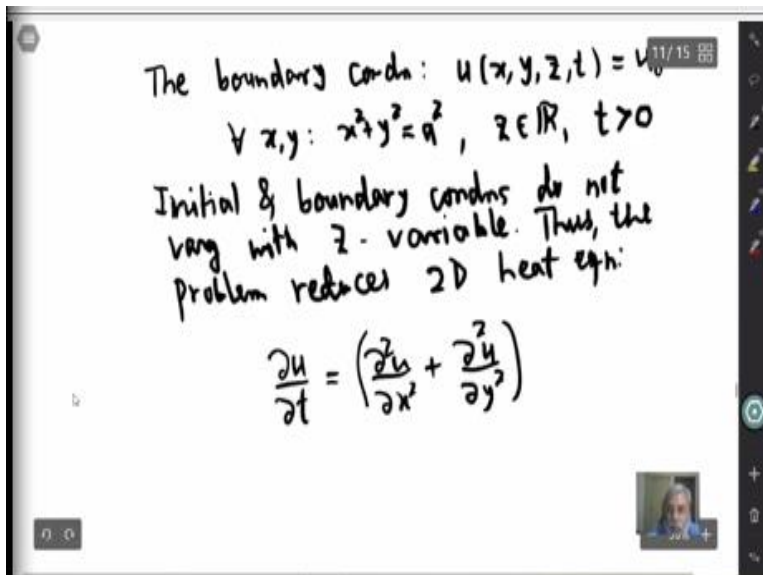

And initially so at $t = 0$, so this metallic cylinder is heated, so assume that $u = 1$.

(Refer Slide Time: 27:40)

And the boundary is maintained at $u = u_0$. So, here I should clarify this one, this initial condition, so let me just say what that is. And then the problem is to analyze what happens for t positive. So, initial condition, so this is just $u(x, y, z, t=0)$ is u_1 for $x^2 + y^2 \leq a^2$ and $z \in \mathbb{R}$, u_1 is just a constant. So, we see that the initial condition and again what is the boundary condition? Boundary condition u of $x, y, z, t = u_0$ for all x, y such that $x^2 + y^2 = a^2$ and again $z \in \mathbb{R}$ and $t > 0$.

(Refer Slide Time: 31:02)

So, we see that this both initial and boundary conditions do not vary with z variable. Thus the problem reduces to two dimensional heating equation. So, $\frac{du}{dt} = \frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2}$. So, here again I am assuming the diffusivity coefficient is 1, so one

can put a number depending on that physical material. So, for simplicity again I am taking this diffusivity constant 1. So, we will continue the analysis of this initial boundary value problem in the next class, thank you.
