Lecture-31
Wave Equation-2

Hello everyone, welcome back, we will continue the discussion how the wave equation in higher dimensions. So, last time we obtained a solution of the wave equation in three dimensions, n equal to 3 looking for radial solutions, when initial data itself is radial. So, it is natural to look for a solution which is also radial. And that motivated us to look for spherical mean function of a given function.

(Refer Slide Time: 01:13)

Darboux equation: $\frac{1}{r^{n-1}} \left[\frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial M_h(x,r)}{\partial r} \right) \right] = \Delta_x M_h(x,r)$

Back to wave eqn: $u_{tt} - c^2 \Delta u = 0$

Consider the spherical mean fn $M_u(x,r,t)$:

Darboux eqn \Rightarrow

$r^{n-1} \Delta_x M_u(x,r,t) = \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial M_u}{\partial r} \right)$

So, we will continue the discussion of the spherical mean function.

(Refer Slide Time: 01:20)

Change of variables:

$$(i) M_h(x, r) = \frac{1}{\sigma_n} \int_{|\xi|=1} h(x+r\xi) dS_\xi$$

Defined for all $r \in \mathbb{R}$, $M_h(x, r) = M_h(x, -r)$

and $h(x) = \lim_{r \rightarrow 0} M_h(x, r)$

$M_h(x, 0) = h(x)$

So, again just I will recall the definition of the spherical mean function and this we already seen in the discussion of Laplace and Poisson equations, so a very useful tool.

(Refer Slide Time: 01:42)

Spherical mean: $h: \mathbb{R}^n \rightarrow \mathbb{R}, C^2$ for

Define M_h as mean value of h over a sphere of radius r , centered at x

$$M_h(x, r) = \frac{1}{\sigma_n r^{n-1}} \int_{|x-y|=r} h(y) dS_y$$

$\sigma_n =$ surface area of the unit sphere in \mathbb{R}^n

$$= \frac{2\pi^{n/2}}{\Gamma(n/2)}$$

So, that is just given any function from \mathbb{R}^n, \mathbb{R} you just define this spherical mean function by taking the mean of the given function h over the balls around a given point x . Sometimes it is also useful to write thinking this as an operator, so instead of M_h , so you think M as an operator. So, that is equal, I will write it.

(Refer Slide Time: 03:06)

Spherical mean: $h: \mathbb{R}^n \rightarrow \mathbb{R}, C^2$ fcn

Define $M_h = M(h)$

mean value of h over a sphere of radius r , centered at x

$$M_h(x, r) = \frac{1}{\sigma_n r^{n-1}} \int_{|x-y|=r} h(y) dS_y$$

$\sigma_n =$ surface area of the unit sphere in \mathbb{R}^n

$$= \frac{2\pi^{n/2}}{\Gamma(n/2)}$$

So, we will write this M sub h as M of h thinking that M is also an operator, it will be useful sometimes. So, given any function h , so this mean value operator M produces another function with one extra independent variable R .

(Refer Slide Time: 03:43)

over a sphere of radius r , centered at x

$$\sigma_n = \text{surface area of the unit sphere in } \mathbb{R}^n$$

$$= \frac{2\pi^{n/2}}{\Gamma(n/2)}$$

$x \in \mathbb{R}^n, r > 0$

Change of variables:

(i) $M_h(x, r) = \frac{1}{\sigma_n} \int_{|\xi|=1} h(x+r\xi) d\xi$

(Refer Slide Time: 03:46)

Change of variables:

$$(1) \quad M_h(x, r) = \frac{1}{\sigma_n} \int_{|\xi|=1} h(x+r\xi) dS_\xi$$

Defined for all $r \in \mathbb{R}$, $M_h(x, r) = M_h(x, -r)$
 and $h(x) = \lim_{r \rightarrow 0} M_h(x, r)$ $M_h(x, 0) = h(x)$
 $\frac{\partial}{\partial r} M_h(x, 0) = 0$

From (1):

And then by change of variable rewrote the spherical mean function and so some important properties we discussed.

(Refer Slide Time: 03:57)

From (1):

$$\frac{\partial}{\partial r} M_h(x, r) = \frac{1}{\sigma_n} \int_{|\xi|=1} \sum_i \frac{\partial h(x+r\xi)}{\partial x_i} \xi_i dS_\xi \leftarrow \text{surface integral}$$

Green's formula

$$= \frac{r}{\sigma_n} \int_{|\xi|<1} \Delta_x h(x+r\xi) d\xi \leftarrow \text{vol. integral}$$

$$= \frac{r}{\sigma_n} \Delta_x \int_{|\xi|<1} h(x+r\xi) d\xi$$

$\int_{\partial\Omega} \Delta u \, d\tau = \int_{\partial\Omega} \frac{\partial u}{\partial \nu} \, dS$
 $= \int_{\partial\Omega} \frac{\partial u}{\partial \nu} \, dS$
 $\Delta u \, d\tau$

(Refer Slide Time: 03:59)

$$\therefore r^{n-1} \frac{\partial}{\partial r} M_h(x, r) = \Delta_x \int_0^r \xi^{n-1} M_h(x, \xi) d\xi$$

$$\Rightarrow \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial}{\partial r} M_h(x, r) \right) = r^{n-1} \Delta_x M_h(x, r)$$

Darboux equation: $\frac{1}{r^{n-1}} \left[\frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial}{\partial r} M_h(x, r) \right) \right] = \Delta_x M_h(x, r)$

Back to wave eqn: $u_{tt} - c^2 \Delta u = 0$

So, the important property is this Darboux equation that connects the Laplacian of the spherical mean function with a second order derivative of the same mean value function with respect to their extra variable r . So, that is an important thing and now we will see how that can be exploited in the study of this wave equation.

(Refer Slide Time: 04:30)

Back to wave eqn: $u_{tt} - c^2 \Delta u = 0$

Consider the spherical mean fn $M_u(x, r, t)$:

Darboux eqn \Rightarrow

$$r^{n-1} \Delta_x M_u(x, r, t) = \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial}{\partial r} M_u \right)$$

Therefore, M_u satisfies the eqn.

So, before coming to this wave equation let us compute do some computation.

(Refer Slide Time: 04:43)

$$u(x, t)$$

$$M_u(x, r, t) = \frac{1}{\sigma_n} \int_{|\xi|=1} u(x+r\xi, t) dS_\xi$$

$$\frac{\partial^2}{\partial t^2} M_u(x, r, t) = \frac{1}{\sigma_n} \int_{|\xi|=1} u_{tt}(x+r\xi, t) dS_\xi$$

In all these things computations are bit lengthy but they are straight forward. So, now we are given a function of 2 variables x and t , x is in \mathbb{R}^n and t is positive. And now we form it is spherical mean function, so now this will be a function of x, r, t . So, we are taking the spherical mean only with respect to the x variable, so this is just let me write it again. So, $\int_{|\xi|=1} u(x+r\xi, t)$, so this is surface integral on the hemisphere.

So, as such if you notice here this integration with respect to ξ variable, so if u is smooth, so I can simply take this Δ_x by Δ_t directly let me take that, $M_u(x, r, t)$. So, this is simply $\frac{1}{\sigma_n} \int_{|\xi|=1} u_{tt}(x+r\xi, t)$, so you simply take the differentiation under the integral side. And similarly if you notice at the x variable, this x variable and ξ variable that is variable of the integration they are also not coupled.

(Refer Slide Time: 07:02)

$$M_u(x, r, t) = \frac{1}{\sigma_n} \int_{|\xi|=1} u(x+r\xi, t) dS_\xi$$

$$\frac{\partial^2}{\partial t^2} M_u(x, r, t) = \frac{1}{\sigma_n} \int_{|\xi|=1} u_{tt}(x+r\xi, t) dS_\xi$$

$$\Delta_x M_u = M_{u_{tt}} = M(u_{tt})$$

So, this we immediately obtained, so this let me stress now $M u$ before that let, so this is nothing but the spherical mean function of u_{tt} . So, if we think this as an operator, so this will write this as. So, the second derivative with respect to t variable of the spherical mean function is same as the spherical mean function of the second derivative of u with respect to t , so that is what it says.
(07:51)

(Refer Slide Time: 07:53)

$$\frac{\partial^2}{\partial t^2} M_u(x, r, t) = \frac{1}{\sigma_n} \int_{|\xi|=1} u_{tt}(x+r\xi, t) dS_\xi$$

$$= M_{u_{tt}} = M(u_{tt})$$

($\frac{\partial^2}{\partial t^2}$ & M commute)

$$\Delta_x M_u(x, r, t) = \frac{1}{\sigma_n} \int_{|\xi|=1} \Delta_x u(x+r\xi, t) dS_\xi$$

$$= M(\Delta_x u)$$

So, this in other words we write this as, so this operator of differentiation and this M they commute, whether you first operate M and then take the derivative that is what is left hand side or you take the derivative first and then take the spherical mean function they are same. And same thing happens with the x variable, so this just let me stress that $M u(x, r, t)$ which is nothing

but (\cdot) (09:04) if x and X_i were coupled, so we cannot do this. But since in the integrand x and X_i are not coupled we can do this and that is same thing as $M \Delta_x u$. So, the importance of the Darboux equation now comes into play. So, Darboux equation relates the Laplacian of the spherical mean function with respect to x with this operator.

(Refer Slide Time: 10:12)

$$\Delta_x M_u(x, r, t) = \frac{1}{\sigma_n} \int_{|\xi|=1} \Delta_x u(x+r\xi, t) d\xi$$

$$\downarrow = M(\Delta_x u)$$

By Darboux eqn,

$$= \frac{1}{r^{n-1}} \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial}{\partial r} M_u \right)$$

$$= \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u$$

So, now you apply the Darboux equation, so this one by Darboux equation. So, this equals to $\frac{1}{r^{n-1}} \frac{\partial}{\partial r} (r^{n-1} \frac{\partial}{\partial r} M_u)$. So, if you perform the differentiation and expand it but this simplifies to $(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r}) M_u$. So, this operator second order operator acting on M .

(Refer Slide Time: 11:28)

$$= \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u$$

Suppose $u_{tt} - c^2 \Delta_x u = 0$

Take spherical mean:

$$M(u_{tt}) - c^2 M(\Delta_x u) = 0$$

$$\rightarrow \frac{\partial^2}{\partial t^2} M_u - c^2 \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u = 0$$

2 variables: t & r $\rightarrow x$ plays the role of r

So, now suppose u is a solution now, the wave equation suppose $u_{tt} - c^2 \Delta u = 0$, so let me just stress that dependence, so this is only with respect to x variables. And now you take spherical mean on both sides of this entire thing. So, spherical, so since this is just an integral, so it is a linear operator, so this is just M of $u_{tt} - c^2 \Delta u$, that is a constant M of $\Delta x u$. And now look at the computations we have done and this is just d^2 by $d t^2$ $M u - c^2$ square d^2 by $d r^2 + n - 1$ by r $d r M u = 0$.

So, if u is a solution of the wave equation then its spherical mean satisfies this equation, so this is our first observation. And in this equation notice that, so x plays only a role of a parameter. So, the spherical mean function now satisfies again a second order equation but in only 2 variables. So, that is what we want because we somehow want to reduce the whole analysis again to one dimensional wave equation, so again we can apply D'Alembert's formula and other things.

So, that is our goal, so we have achieved now, so this look at here, so the spherical mean function of u satisfies a second order equation but only 2 variables, so that is important, t and r . So, what about the initial condition? So, initial conditions are prescribed on the solution u at $t = 0$ and again taking the mean value. So, they transform to initial values for the spherical mean function and that is what I have written here.

(Refer Slide Time: 15:16)

Darboux eqn \Rightarrow

$$r^{n-1} \Delta_x M_u(x, r, t) = \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial}{\partial r} M_u \right)$$

Therefore, M_u satisfies the eqn:

$$\frac{\partial^2}{\partial t^2} M_u - c^2 \frac{\partial}{\partial r} \left(r^{n-1} \frac{\partial}{\partial r} M_u \right) r^{-n} = 0$$

Or

$$\frac{\partial^2}{\partial t^2} M_u - c^2 \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u = 0$$

So, taking the spherical mean function of the solution u .

(Refer Slide Time: 15:23)

Therefore, M_u satisfies the eqn:

$$\frac{\partial^2}{\partial t^2} M_u - c^2 \frac{\partial}{\partial r} (r^{n-1} \frac{\partial}{\partial r} M_u) \cdot r^{-n} = 0$$

or

$$\frac{\partial^2}{\partial t^2} M_u - c^2 \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u = 0$$

$\partial_r = \frac{\partial}{\partial r}$

Euler-Poisson-Darboux eqn

We just saw that it satisfy this equation and this has a name, it is called Euler-Poisson-Darboux equation. Again if this term, this first order this is just del r is, so I am mixing that same notation del by del r. So, if this first order derivative were absent then we simply get a wave equation in one dimension. But in the presence of this, so there are some difficulties and that we already seen.

(Refer Slide Time: 16:11)

Case n=3:

initial condns $\left\{ \begin{array}{l} M_u(x, r, 0) = M_\phi(x, r) \quad [u(x, 0) = \phi(x)] \\ \frac{\partial}{\partial t} M_u(x, r, 0) = M_\psi(x, r) \quad [u_t(x, 0) = \psi(x)] \end{array} \right.$

Put $v(x, r, t) = r M_u(x, r, t)$

Then, $v_{tt} - c^2 v_{rr} = 0$

$v(x, r, 0) = r M_\phi(x, r)$

So, again we go back to the case $n = 3$, so the initial conditions at $t = 0$ on u now are transformed to initial conditions for the spherical mean function, so this initial conditions at $u = 0$. So, here sorry let us stream level here, (()) (16:44) so we are given these initial conditions of u and now

we are just transforming them to r . So, again first consider the case $n = 3$, we will come back to the general case of M later. Because the transformation is little more complicated, so for $n = 3$ it is very simple one. So, again you put V of x, r of x , so the function of x, r, t , this r into M of x, r, t .

(Refer Slide Time: 17:29)

Then, $V_{tt} - c^2 V_{rr} = 0$

$$\begin{cases} V(x, r, 0) = r M_\phi(x, r) \\ V_t(x, r, 0) = r M_\psi(x, r) \end{cases}$$

D'Alembert's formula gives

$$V(x, r, t) = \frac{1}{2} \left[(r+ct) M_\phi(x, r+ct) + (r-ct) M_\phi(x, r-ct) \right] + \frac{1}{2c} \int_{r-ct}^{r+ct} \xi M_\psi(x, \xi) d\xi$$

And as we observed earlier, so this V satisfies this wave equation in one dimensions. And what are the initial conditions for V ? They are almost same as this spherical mean function M of x (17:45) out for this factor r so V of $x, r, 0$ is our M mean value of ϕ and the first derivative of V at $t = 0$ is $r M_\psi$. So, again you just observe that x is just a, it is role is only as a parameter. Now V satisfy this wave equation in one dimensional wave equation with these initial conditions. So, we can immediately use the D'Alembert's formula and write down the solution. So, these are the initial conditions, just here.

(Refer Slide Time: 18:34)

$$+\frac{1}{2c} \int_{r-ct}^{r+ct} \xi M_\psi(x, \xi) d\xi \quad \left| \begin{array}{l} M_h(x, -r) \\ = M_h(x, r) \end{array} \right.$$

$(M_h(x, r) \text{ is an even fn of } r)$

$$\therefore M_u(x, r, t) = \frac{1}{2r} [(ct+r)M_\varphi(x, ct+r) - (ct-r)M_\varphi(x, ct-r)]$$

$$+\frac{1}{2cr} \int_{ct-r}^{ct+r} \xi M_\psi(x, \xi) d\xi$$

UAE: $u(x, t) = \lim_{r \rightarrow 0} M_u(x, r, t)$

So, this is first part coming from the initial condition at $t = 0$ and this is the derivative. So, this is just by D'Alembert's formula. Now you want to rewrite this little bit, so here, so recall this the mean value function is any one function of r . So, that we already observed just by the definition, so this $M_\psi(x, r - ct)$ I can write as $ct - r$. So, to keep the same notation here, so I want to write $ct - r$ also here but that produces a negative sign, so that is what I have written here.

So, there is no, this is same as $M_\psi(x, r - ct)$ but this one I write as $ct - r$, so it will be clear why you are writing that. And again same thing, so this is an even function and we are multiplying by an odd function ξ , so this is whole thing is again an odd function. So, if you substitute and do some work, so we can replace this $r - ct$ by $ct - r$, so that is what with the observation. And this r is coming because of this V , V is $r M_u$, so M_u is V by r , so V there is no r , so we just divide by r , so we get this here.

So, we have obtained a formula for the spherical mean function of the solution and from there would like to get a formula for u itself. And this is where again this usefulness of the spherical mean functions come into play. So, if we take the limit as r goes to 0 we get back the original function, so this is what we have to do. So, we have to take limit of this right hand side as r goes to 0 , so there is r in the denominator, so we have to exercise little here there. So, let me just do one by one.

(Refer Slide Time: 21:47)

$$\lim_{r \rightarrow 0} \frac{1}{2r} [(ct+r)M_\varphi(x, ct+r) - (ct-r)M_\varphi(x, ct-r)]$$

$$= \frac{\partial}{\partial t} (tM_\varphi(x, ct))$$

$$f'(x_0) = \lim_{h \rightarrow 0} \frac{f(x_0+h) - f(x_0)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{f(x_0+h) - f(x_0-h)}{2h}$$

So, first let me take that first term, what happened to the limit $\frac{1}{2r}$ of this function $ct + r M_\varphi(x, ct+r) - ct - r M_\varphi(x, ct-r)$. So, what is this? As $r \rightarrow 0$, just we want to convert this into a derivative, so how we can do that? So, if you have any functions, so this is just one variable function. So, we know that the derivative, we simply limit you have found $(\frac{\partial}{\partial t})$ (23:42). So, this is plain definition function of one variable.

So, this is also equal to limit $\frac{f(x_0+h) - f(x_0-h)}{2h}$. And we are in such a situation, so here is our function if you take this ct into $M_\varphi(x, ct)$, you take that as the function. And then you apply this formula for the derivative, so what we get is derivative of t into simply derivative. But, so this is simply just work it out, so this is $\frac{d}{dt}$ of $t M_\varphi(x, ct)$. So, just use this definition of the derivative you will get that. The second one is much easier, so that is the integral. So, here it is just integral, so you get just the mean value of this integral, so this let me write that.

(Refer Slide Time: 26:11)

$$\lim_{r \rightarrow 0} \frac{1}{2cr} \int_{ct-r}^{ct+r} \xi M_\psi(x, \xi) d\xi = \frac{1}{2c} [2ct M_\psi(x, ct)] = t M_\psi(x, t)$$

Thus, the soln of IVP:

$$u_{tt} - c^2 \Delta u = 0 \text{ in } x \in \mathbb{R}^3, t > 0$$

$$u(x, 0) = \varphi(x), u_t(x, 0) = \psi(x), x \in \mathbb{R}^3$$

has the representation:

So, 1 by this only (()) (26:18) as r tends to 0, 1 by 2cr integral ct - r ct + r Xi M psi x, Xi, d Xi = 1 by, so that there is a c there, we write that c, ct M Xi x, t maybe there is a 2 there and that just simply comes to t M Xi x, t. So, as I said computations are bit lengthy but they are straightforward. So, thus the solution of IVP, so finally we can write that u tt - c square Laplacian u = 0, remember we are dealing only in n = 3, so let me just stress that. Because this is not the formula for generally n, so this with initial conditions u of x 0 = pi x u sub t x 0 = psi x in x in R 3 has the representation.

(Refer Slide Time: 29:55)

$$u(x, t) = t M_\psi(x, ct) + \frac{\partial}{\partial t} (t M_\varphi(x, ct))$$

$$= \frac{t}{4\pi} \int_{|\xi|=ct} \psi(x+ct\xi, ct) \frac{dS_\xi}{d\xi} + \frac{\partial}{\partial t} \left[\frac{t}{4\pi} \int_{|\xi|=ct} \varphi(x+ct\xi, ct) dS_\xi \right]$$

So, let me write that u of x, t = t M psi x ct + d by dt of t M phi x, ct, where M psi and M phi are the spherical mean functions of psi and phi. So, we can express directly in terms of that, so this is

just t by, so in $n = 3$, σ_3 is just 4π , so let me just write that integral mod ct ψ of $x + ct$ X_i ct dX_i and similarly this one. So, d by dt of this big expression t by 4π integral mod $X_i = ct$ ψ of $x + ct$ X_i ct dS_{X_i} . So, these are surface integrals, let us not forget that, so this is dS_{X_i} .

(Refer Slide Time: 32:37)

$$u(x,t) = \frac{1}{4\pi c^2 t} \int_{|y-x|=ct} \psi(y) dS_y$$

$$+ \frac{\partial}{\partial t} \left[\frac{1}{4\pi c^2 t} \int_{|y-x|=ct} \varphi(y) dS_y \right]$$

(n=3)

verification that u is a soln of IVP
requires computations.

So, again by change of variable we can write. So, this is 1 by $4\pi c^2 t$ surface integral $y - x = ct$ ψ of y dS_y , so this is the surface measure on the surface, so y that variable $+ d$ by dt of 1 by $4\pi c^2 t$ $y - x = ct$ φ of y dS_y . So, again just I will stress, so this is the formula for $n = 3$ let remember that. And so even though this looks very simple one, so the verification that u satisfies u is a solution of IVP.

So, that is not straightforward, so it requires some work, require some competition. So, for example even verification of the initial conditions, so straight away we cannot put $t = 0$, so because there is a t in the denominator. So, we have to only take this limit as t go to 0 , so that requires work.

(Refer Slide Time: 35:27)

Thus, the soln of IVP:

$$u_{tt} - c^2 \Delta u = 0 \text{ in } x \in \mathbb{R}^3, t > 0$$

$$u(x, 0) = \varphi(x), u_t(x, 0) = \psi(x), x \in \mathbb{R}^3$$

has the representation:

$$u(x, t) = t M_\psi(x, ct) + \frac{\partial}{\partial t} (t M_\varphi(x, ct))$$

$$= \frac{t}{4\pi} \int_{|x-\xi|=ct} \psi(x+c\xi, ct) \frac{dS_\xi}{|\xi|} + \frac{\partial}{\partial t} \int_{|x-\xi|=ct} \varphi(x+c\xi, ct) \frac{dS_\xi}{|\xi|}$$

So, even just verification of the initial conditions is not straightforward in this case, so in the case of D'Alembert's formula that was very straightforward. But here we have to do some computation, so we have to take the limit. And in the next class we will further analyze what the solution and what are the qualitative properties of the solution? Again domain of dependence, range of influence and we will also come across the Huygens' principle and what does that mean? So, we will discuss all these things in the next class, starting from this representation of the solution in $n = 3$, thank you.
