Lecture - 34
Wave Equation 5

(Refer Slide Time: 00:20)

Telegraph Equation

A general 2nd order eqn in one space variable:

$$u_{tt} - c^2 u_{xx} + \alpha u_x + \beta u_t + \gamma u = 0$$

α, β, γ are constants. $x \in \mathbb{R}, t > 0$

Put $v(x,t) = \exp(ax+bt) u(x,t)$

$$v_t = \exp(ax+bt)(bu + u_t)$$

$$v_{tt} = \exp(ax+bt)(b^2u + 2bu_t + u_{tt})$$

Hello everyone, welcome back we continue discussion on wave equation in more than one dimension. In this lecture we discuss another interesting application of method of descent to the so called telegraph equation. So, now we are going to descent from 2; dimensional wave equation; to a second order equation in one space dimensions. So, let me start with the problem. So, let me start with the general second order equation. So, the principal part that is the terms containing the highest derivative tilde wave operator.

And now, we add these lower order terms $\alpha u_x + \beta u_t + \gamma u = 0$, where all α, β, γ are constants. So, we make some simplifications. Some simplifications are possible here. So, we can get rid of certain terms by simple change of variables. So, for that purpose so, we put V of x, t is equal to exponential of $ax + bt$ into u of x, t . So, u satisfied this given equation and now we will see what this V satisfies if we choose appropriate constants a and b so, a and b are constants. So, simple differentiation, so product rule and Leibniz rule.

(Refer Slide Time: 02:30)

$$u_{tt} - c^2 u_{xx} + \alpha u_x + \beta u_t + \gamma u = 0$$

α, β, γ are constants. $x \in \mathbb{R}, t > 0$

Put $V(x,t) = \exp(ax+bt) u(x,t)$

$$V_t = \exp(ax+bt) (bu + u_t)$$
$$V_{tt} = \exp(ax+bt) (b^2 u + 2bu_t + u_{tt})$$
$$V_x = \exp(ax+bt) (au + u_x)$$
$$V_{xx} = \exp(ax+bt) (a^2 u + 2au_x + u_{xx})$$
$$V_{tt} - c^2 V_{xx} = \exp(ax+bt) \{ u_{tt} - c^2 u_{xx} + b^2 u + 2bu_t - a^2 c^2 u - 2ac u_x \}$$

So, we find these derivatives of V with respect to t and x . So, they are very easily computable. So, here are the expressions for the first and second derivatives of V in terms of those of u . And now, let us form this $V_{tt} - c^2 V_{xx}$. So, looking at the expressions here, so, this exponential factor is common. So, you take that exponential term outside and then inside you have $u_{tt} - c^2 u_{xx} + b^2 u + 2bu_t - a^2 c^2 u - 2ac u_x$ coming from the second derivatives. So, V_{tt} there is u_{tt} here, there is u_{xx} here, so that is fine.

But they also contain lower order terms u and u_t , so those are added here. So, we have $b^2 u + 2bu_t - a^2 c^2 u - 2ac u_x$. So, these constants a and b are at our disposal. So, we can choose them. So, here we make the choice. So, you choose $2b = \beta$. So, β is in the given equation. So, α, β, γ are in the given equation.

(Refer Slide Time: 04:12)

$$\begin{aligned}
 V_{tt} &= \exp(ax+bt)(b^2u + 2bu_t + u_{tt}) \\
 V_x &= \exp(ax+bt)(au + u_x) \\
 V_{xx} &= \exp(ax+bt)(a^2u + 2au_x + u_{xx}) \\
 V_{tt} - c^2V_{xx} &= \exp(ax+bt)\{u_{tt} - c^2u_{xx} \\
 &\quad + \underbrace{b^2u + 2bu_t}_{=\beta} - \underbrace{a^2c^2u - 2ac^2u_x}_{=-\alpha}\} \\
 &= \exp\{ax+bt\} \underbrace{(b^2 - a^2c^2 - \gamma)}_{=-\lambda} u \\
 &= -\lambda V
 \end{aligned}$$

$$V_{tt} - c^2V_{xx} + \lambda V = 0$$

So, this coefficient of the first derivative of u with respect to t , so that is β there. So, you choose this $2b = \beta$. And similarly, this $2ac^2 = -\alpha$. So, we this choice. So, now, since you satisfy this equation, so let us do that. So, $u_{tt} - c^2u_{xx} + \alpha u_x + \beta u_t = -\gamma u$ and that is what I have written here. And these 2 things are coming from this change of variable. So, there are u terms also here. So, $b^2 - a^2c^2 - \gamma$. And let us call this constant the coefficient of u as $-\lambda$.

And again so if I take that λ out so this product is precisely v . So, with this change of variables, so this function V satisfies this second order equation.

(Refer Slide Time: 05:24)

$$\begin{aligned}
 V_{tt} - c^2V_{xx} &= \exp(ax+bt)\{u_{tt} - c^2u_{xx} \\
 &\quad + \underbrace{b^2u + 2bu_t}_{=\beta} - \underbrace{a^2c^2u - 2ac^2u_x}_{=-\alpha}\} \\
 &= \exp\{ax+bt\} \underbrace{(b^2 - a^2c^2 - \gamma)}_{=-\lambda} u \\
 &= -\lambda V
 \end{aligned}$$

$$V_{tt} - c^2V_{xx} + \lambda V = 0$$

Telegraph equation (also v replaced by v_t)

$$\text{IVP: } u_{tt} - c^2u_{xx} + \lambda u = 0$$

So there is, so it is not wave equation but it is there is a term lambda V comes in there. And this is called the telegraph equation. In the literature you also find that so, is this you replace this V by V t that is also called telegraph equation in some textbooks. In either case now, just now we have learned that even if it is V t, we can always transform that equation to an equation of this form. So, since a general second order equation of this form can always be reduced to the telegraph equation. We now consider the initial value problem for this telegraph equation. So, just remember here, so, this is the x is in r.

(Refer Slide Time: 06:35)

$= -\lambda v$

$$v_{tt} - c^2 v_{xx} + \lambda v = 0$$

Telegraph equation (also v replaced by v_t)

IVP: $u_{tt} - c^2 u_{xx} + \lambda u = 0$
 $u(x,0) = \varphi(x), u_t(x,0) = \psi(x)$

Write $x_1 = x$; consider $(x_1, x_2, t) = u(x_1, t) c_{(c^2)}$

So, this is one space domain. Just remember that. So, the only difference between wave equation and this is that we have a lower order term namely $\lambda u = 0$. And since your second order equation, so, we prescribe 2 initial conditions. So, this is the initial value problem. Now, try to obtain a formula for the solution using the method of descent.

(Refer Slide Time: 07:18)

Telegraph equation

2/10

IVP: $u_{tt} - c^2 u_{xx} + \lambda u = 0$

$x \in \mathbb{R}$
 $t > 0$

$u(x, 0) = \varphi(x), u_t(x, 0) = \psi(x)$

Write $x_1 = x$; consider $(\lambda > 0)$

$V(x_1, x_2, t) = u(x_1, t) \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right)$

$V_{tt} = u_{tt} \cdot \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right), V_{x_1 x_1} = u_{x_1 x_1} \cdot \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right)$

$V_{x_2 x_2} = -\frac{\lambda}{c^2} \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right) u(x_1, t)$

So, for that purpose so, just write the $x_1 = x$ and consider this function so, first assume that this coefficient lambda is positive. So, if lambda equals to 0 this is just one dimensional wave equation and we already know that D'Alembert's formula gives us this solution. So, first assume this lambda is positive. And consider this function of 2 space variables now, V of $x_1 \times x_2 \times t$ which is equal to u of $x_1 \times t$. So, again u is solution of that equation into \cos root lambda by $c \times x_2$. So, this is you can say separated when you see x_1 and x_2 are separated here.

So, since I am assuming lambda positive so, the root lambda is also positive. And again simple computations so, x_2 comes only here. So, the second, derivative of V with respect to t same as second derivative of u with respect to t into this cosine factor. And similarly, the second derivative with respect to x_1 variable so x_2 is only there so, get $u_{x_1 x_1}$ into \cos of this variable. What about $V_{x_2 x_2}$ the second derivative of V with respect to x_2 variable and that is all you have to differentiate this cosine function.

So, if we differentiate cosine function place we get back again cosine function with a negative sign. Of course, this constant also will produce a constant here that is λ / c^2 .

(Refer Slide Time: 09:27)

$$v_{x_2 x_2} = -\frac{\lambda}{c^2} \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right)$$

$$\therefore v_{tt} - c^2 (v_{x_1 x_1} + v_{x_2 x_2}) = 0$$

$$= \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right) \{u_{tt} - c^2 u_{x_1 x_1} + \lambda u\}$$

$$= 0$$

$$\therefore v_{tt} - c^2 \Delta_2 v = 0 \rightarrow \text{2D wave eqn}$$

$$v(x_1, x_2, 0) = \varphi(x_1) \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right)$$

$$v_t(x_1, x_2, 0) = \psi(x_1) \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right)$$

And now, you see that compute this wave operator on V . So, $V_{tt} - c^2 (V_{x_1 x_1} + V_{x_2 x_2}) = 0$. So, this is nothing but in our earlier notation, so, temporary notation. So, this is the Laplacian in 2 dimensions. And you plug in these computations. So, again this cosine factor is everywhere so that comes out and in the bracket you have $u_{tt} - c^2 u_{x_1 x_1} + \lambda u$ and u since you satisfy the given equation. So, that is 0 so u satisfy the telegraph equation then with this change of variables V satisfies the wave equation. So, this is 2D wave equation.

So, what about the initial conditions so, they are also very easy to compute. So, only t appears in this factor there is no t there. So, this $u(x_1, 0)$ is just φ of x_1 and $u_t(x_1, 0)$ is ψ of x_1 and that just multiplies by this cosine factor. And important to notice again just look at this transformation we are using so, we get back

(Refer Slide Time: 11:18)

$$= \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right) \left\{ u_{tt} - c^2 u_{x_1 x_1} + \lambda u \right\}$$

$$= 0$$

$\therefore \begin{cases} v_{tt} - c^2 \Delta_2 v = 0 \rightarrow \text{2D wave eqn} \\ v(x_1, x_2, 0) = \varphi(x_1) \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right) \\ v_t(x_1, x_2, 0) = \psi(x_1) \cos\left(\frac{\sqrt{\lambda}}{c} x_2\right) \end{cases}$

Once v is found, we can recover u by

$$u(x_1, t) = v(x_1, 0, t)$$

Once we know, once V is found we can recover u by this way very simple thing. So, V of x_1 you put there 0. So that cosine factor when you put $x_2 = 0$ produces 1 and we get back our original function. And now, since V satisfies 2 dimensional wave equation we can use Kirchhoff formula we have already derived and then in the solution which just substitute $x_2 = 0$, then we get back our required solution u .

(Refer Slide Time: 12:43)

Kirchoff's formula:

$$V(x_1, x_2, t) = \frac{1}{2\pi c} \iint_{B_{ct}(x)} \frac{\psi(y_1) \cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{\sqrt{c^2 t^2 - r^2}} dy_1 dy_2$$

$$+ \frac{\partial}{\partial t} \left\{ \dots \right\}$$

$$r^2 = (x_1 - y_1)^2 + (x_2 - y_2)^2$$

First integrate w.r.t. y_2 & then w.r.t. y_1 :

$$\iint \psi(y_1) \cos\left(\frac{\sqrt{\lambda}}{c} y_2\right) dy_1 dy_2$$

So, by Kirchhoff formula so, this is Kirchhoff formula gives us 2 dimension. So, V of $x_1 \times x_2 \times t$ is $1/2\pi c$ double integral over this ball of radius ct centered at x into the initial condition comes into picture. So, initial conditions are here ψ for V_t . So, ψ of $y_1 \cos$ of $\sqrt{\lambda} y_2 / c$ square t square - r square root $dy_1 dy_2$ just recall. So, this we derived in the previous class and

then the second term coming from the other data file. So d/dt , so same term except that ψ replaced by ϕ and here again r^2 is $x_1^2 + y_1^2 + x_2^2 + y_2^2$.

So that is the notation for this. And since this double integral and more or less the variables y_1 and y_2 are separated, they are still together here but at least in the numerator they are separated. So, let us write this double integral as iterated integral first integrating with respect to y_2 and then with respect to y_1 . That is what I have written here.

(Refer Slide Time: 14:43)

The slide shows the following handwritten work:

$$B_{ct}(x) = \iint \frac{\psi(y) \cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{\sqrt{c^2 t^2 - r^2}} dy_1 dy_2$$

$$= \int_{x_1-ct}^{x_1+ct} \psi(y_1) dy_1 \left\{ \int_{x_2-s}^{x_2+s} \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{\sqrt{c^2 t^2 - r^2}} dy_2 \right\}$$

$S = \sqrt{c^2 t^2 - (x_1 - y_1)^2}$. Put $x_2 = 0$

Inner integral:

$$\int_{-s}^s \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{(s^2 - y_2^2)^{1/2}} dy_2 = 2 \int_0^s \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{(s^2 - y_2^2)^{1/2}} dy_2$$

So, this double integral we are writing as iterated integral first with respect to y_2 variable and then with respect to y_1 variable. So, it is easy to calculate the limits in the integral of both variables y_1 and y_2 . And again some notation here. So, this S is $c^2 t^2 - x_1^2 - y_1^2$. So, just writing the double integral as it gets. Now comes the important part. So, we are not interested in this solution V in the entire $x_1 \times x_2$ plane but you are just interested in the line $x_2 = 0$. So, that will give us just remember that $u = x_1 t$ and that is what we want.

So, if you put $x_2 = 0$ the inner integral just look at the inner integral here. So that becomes $\int_{-s}^s \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{(s^2 - y_2^2)^{1/2}} dy_2$ and put the half. So, this one now we have written slightly different here. So, taken this $x_1^2 + y_1^2$ separately in that S and only y_2 there. And you will see that this integral is an even function of y_2 and this is symmetric

interval about the origin. So, we can write this as 2 times integral 0 to s and this form suggests that to use a change of variable.

(Refer Slide Time: 17:06)

$$\int_{-s}^s \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{(s^2 - y_2^2)^{1/2}} dy_2 = 2 \int_0^s \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{(s^2 - y_2^2)^{1/2}} dy_2$$

Change of variable: $y_2 = s \cdot \sin \theta$

$$= 2 \int_0^{\pi/2} \cos\left(\frac{\sqrt{\lambda}}{c} s \sin \theta\right) d\theta$$

$$= 2 \cdot \frac{\pi}{2} J_0\left(\frac{\sqrt{\lambda}}{c} s\right)$$

Bessel's fn

$$J_0(z) = \frac{2}{\pi} \int_0^{\pi/2} \cos(z \sin \theta) d\theta, \quad z \in \mathbb{R}$$

Very simple change of variable namely $y_2 = s \sin \theta$ and that removes this new denominator and we get a very simple looking formula namely integral 2 times that remains the 0 to $\pi/2$ cosine root λ/c $s \sin \theta$ $d\theta$. So, we are using this change of variable here. So, $y_2 = s \sin \theta$. So, when y_2 is s you get $\pi/2$. So, that changes and this one this integral is again Bessel and that is related to the Bessel function of order 0 of the first kind.

(Refer Slide Time: 18:17)

$$\int_{-s}^s \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{(s^2 - y_2^2)^{1/2}} dy_2 = 2 \int_0^s \frac{\cos\left(\frac{\sqrt{\lambda}}{c} y_2\right)}{(s^2 - y_2^2)^{1/2}} dy_2$$

Change of variable: $y_2 = s \cdot \sin \theta$

$$= 2 \int_0^{\pi/2} \cos\left(\frac{\sqrt{\lambda}}{c} s \sin \theta\right) d\theta$$

$$= 2 \cdot \frac{\pi}{2} J_0\left(\frac{\sqrt{\lambda}}{c} s\right)$$

Bessel's fn

$$J_0(z) = \frac{2}{\pi} \int_0^{\pi/2} \cos(z \sin \theta) d\theta, \quad z \in \mathbb{R}$$

of order 0 and of first kind

$$\therefore u(x,t) = u(x,0) = V(x,0,t)$$

So, Bessel function has different representations and one such representation is this given by this integral. So, this Bessel functions of order 0 and of first kind. So, some material regarding this Bessel function so, we have been using given heat equation and it has again cropped up in this solution of the telegraph equation. So, that those things will be written down and provided for your reading. So finally, so just so the same inner integral that we have computed now, so thus is in terms of the Bessel function, so now we just put together so, we get the required solution.

(Refer Slide Time: 19:39)

$$\begin{aligned} \therefore u(x,t) &= u(x_1,t) = v(x_1,0,t) \\ &= \frac{1}{2c} \int_{x_1-ct}^{x_1+ct} J_0\left(\frac{\sqrt{\lambda}}{c}s\right) \psi(y_1) dy_1 \\ &\quad + \frac{\partial}{\partial t} \left(\right) \end{aligned}$$

$J_0(0) = 1$

$s^2 = c^2 t^2 - (x_1 - y_1)^2$

So, again go back to the original variable u of x t so that temporarily we put it as x_1 and this one is given by $v(x_1,0,t)$ and that is just now computed. It is $1/2c$ $x_1 - ct$ to $x_1 + ct$ J_0 root λ S \sin ψ and same thing comes here if ψ replaced there by ϕ . I am noticed that if λ is 0 this J_0 of 0. In our definition is to solve a normalized to be 1. So, if λ is 0 the telegraph equation reduces to the wave equation. So, if λ is 0 it reduces to the wave equation and that you can see given in this formula.

So, when λ is 0 this is just one so this is presiding what is there in the D'Alembert's formula. So, this formula now involves some additional term in the integral unknown function. That is important so this Bessel function of order 0 it is very well studied and all these properties are recorded. Now what about the situation, so here we started with λ positive. So, what if is negative or less.

(Refer Slide Time: 21:44)

The case of $\lambda < 0$

$$u_{tt} - c^2 u_{xx} - \lambda u = 0, \lambda > 0$$

$$x_1 = x,$$

$$v(x_1, x_2, t) = u(x_1, t) \cosh\left(\frac{\sqrt{\lambda}}{c} x_2\right)$$

Cosine hyperbolic for $\frac{\lambda + \lambda^2}{2}$

$$v_{x_2 x_2} = u(x_1, t) \cosh\left(\frac{\sqrt{\lambda}}{c} x_2\right) \cdot \frac{\lambda}{c^2}$$

$$v_{tt} - c^2 \Delta_2 v = 0$$

So, the case is very simple again. So, now write the equation $u_{tt} - c^2 u_{xx}$, so instead of writing plus lambda you are assuming lambda positive so you just write 0. And now again you write $x_1 = x$ and consider the function V of x_1, x_2, t is equal to same thing. So, now we will just instead of cos you just use cos hyperbolic $\sqrt{\lambda} / c \cdot x_2$ that is the only difference. So, all the computations are same. The only difference now is if you compute the second derivative with respect to x_2 variable of this function V .

So, this is just cos. So, this will not change the sign. Earlier we had since we had only cos, so second to produce a minus cos, but for hyperbolic function so this is cosine hyperbolic function. So, just recover what that is, so same computations. So, now you see that this again this function V satisfies the 2 dimensional wave equation. And now the initial conditions on u get transform to V with the additional factor of cosine hyperbolic.

(Refer Slide Time: 25:25)

$V_{tt} - c \Delta_2 V = 0$

$u(x, t) = v(x, 0, t)$

Bessel's fn of order 0 & of second kind:

$$I_0(z) = \frac{2}{\pi} \int_0^{\pi/2} \cosh(z \sin \theta) d\theta$$

And again important thing is so we recover this; our function just by putting $x^2 = 0$. So that is you want easy recovery of original function. It is important. And if you do the same computation again so V satisfies now this V everything is same except that now you get instead of \cos you get \cosh . That the only difference and that is also called a Bessel function of the second kind of order 0 and of second kind.

So, the second I_0 it is denoted by I . So, the first kind denoted by J , so the only difference in just replace this by \cos . So, I just want you to there this in mind because we will be considering similar problems but the Laplace equation and may be one path heat equation. So, what we have shown here is just is telegraph equation. But it is more like an Eigenvalue problem.

(Refer Slide Time: 28:05)

$$u_{tt} - c^2 u_{xx} + \lambda u = 0$$
 There is a soln for all $\lambda \in \mathbb{R}$

So, what we are shown is there is a solution that is unique for all lambdas. If you think this as wave operator and so we are showing that so each real number is an Eigenvalue on that operator. So, I want to just comment on that. So again, then we will come back to Laplace equation, we have occasion to recall this. So that is fine. So, just so far what we have done.

(Refer Slide Time: 29:29)

- Method of spherical means
- Euler-Poisson-Darboux eqn
- $n=3$
- Method of descent: $n=2$
- Telegraph eqn

So, just introduce the method of spherical means, just summarize. And then we derived this Euler-Poisson dot equation and with that help you could obtain solution case $n = 3$ by simple transformation and reducing the whole problem again to one dimensional wave equation and then by method of descent. So, we obtained the formula for the $n = 2$ case and using again the method of descent. So, we also form for the telegraph equation.

(Refer Slide Time: 31:08)

What about $n > 3$?

IVP: $u_{tt} - c^2 \Delta u = 0, x \in \mathbb{R}^n, t > 0$
+ I.C.

Spherical mean fn: $M_u(x, r, t)$:

$$\frac{\partial^2}{\partial t^2} M_u - c^2 \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u = 0$$

And what about other n ? That is our next question. So, at least we should answer little bit regarding that, I will just explain and we will continue next time discussion on that. So, this is the IVP for the wave equation. So, this is actually \mathbb{R}^n and t positive plus initial condition, let me not bother about that now and what we did was you this method your spherical means, so, that spherical mean function $M_u(x, r, t)$ and that satisfies Euler-Poisson dot wave equation. So, this is again the second order equation but only in 2 variables equal to 0.

So, this is Euler-Poisson dot wave equation, so when $n = 3$ by simple transformation by multiplying this spherical mean function M_u / r we could reduce that to one dimensional wave equation. So, when n is bigger than 3 certainly that will not work. So, we have to look for a different kind of transformation. So, what we look for is an operator?

(Refer Slide Time: 33:33)

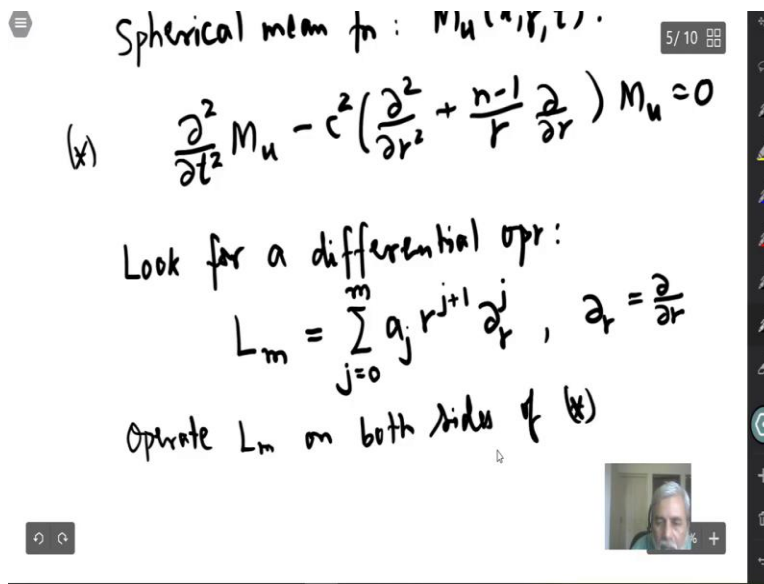

Spherical mem fn: $M_u(t, r, \theta)$

(*) $\frac{\partial^2}{\partial t^2} M_u - c^2 \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u = 0$

Look for a differential opr:

$$L_m = \sum_{j=0}^m a_j r^{j+1} \partial_r^j, \quad \partial_r = \frac{\partial}{\partial r}$$

Operate L_m on both sides of (*)

Look for a differential operator I denoted by L_m . So, this is $j = 0$ to m a j r to the power $j + 1$ $d r$ j . So, this operator $d r$ is essentially an ordinary differential operator because only r variable there but since we are also dealing with t . So, let me denote it by the partial derivative. So, what we want to do is this operate L_m so if you call this star there. So, operate L_m on both sides of star, so what we get is just write that and then continue next time.

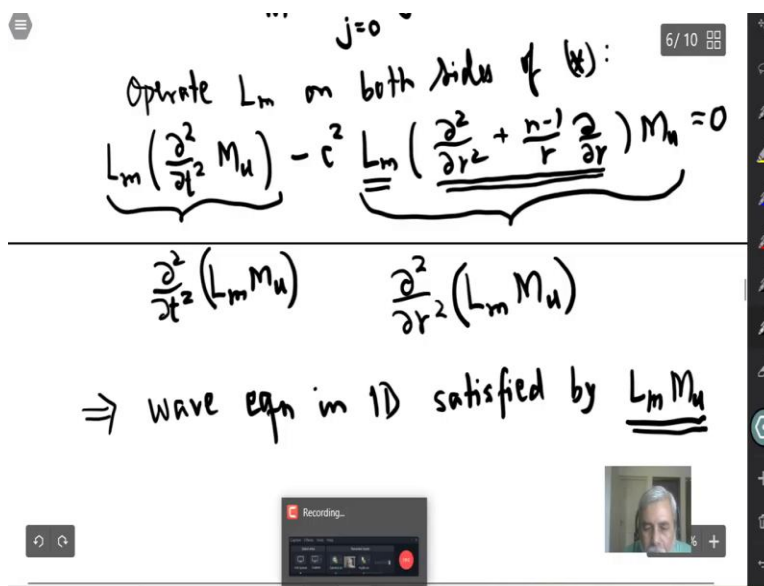

(Refer Slide Time: 35:11)

Operate L_m on both sides of (*):

$$L_m \left(\frac{\partial^2}{\partial t^2} M_u \right) - c^2 \underbrace{L_m \left(\frac{\partial^2}{\partial r^2} + \frac{n-1}{r} \frac{\partial}{\partial r} \right) M_u}_0 = 0$$

$$\frac{\partial^2}{\partial t^2} (L_m M_u) \quad \frac{\partial^2}{\partial r^2} (L_m M_u)$$

\Rightarrow wave eqn in 1D satisfied by $L_m M_u$

So, this L_m so that is a linear operator. So, given star is also a linear equation. So, there is absolutely no problem. So, the L_m this operator, there is absolutely no problem here this will just become $\text{del}^2 / \text{del} t^2$ because this t variable and that is r variable. So, there is no problem so $L_m M_u$. But this is also a differential operator containing r derivatives and this is

also differential operator in r variables, so in general, there will not be commutativity, so I cannot just push this $L m$ inside just like I did here. So, there will be some extra terms that will crop up.

And that somehow you want to reduce it to remember this is our work $L m M u$. So, if we succeed in doing that, so, when I operate the $L m$ on this operator, I should get this $\Delta^2 / \Delta r^2 L m M u$ and then we get wave equation in 1 D satisfied by $L m$. So, the first task is to find this $L m$. And then we have to also get back our original function u from all these operations, so that should that process of getting back u also should be simpler. And we will discuss these things in detail in the next class. Thank you.
