

Matric Theory
Professor. Chandra R. Murthy
Department of Electrical Communication Engineering
Indian Institute of Science, Bangalore
Course introduction and properties of matrices

So, good morning again everyone, we will start now. So, welcome to E2-212, this is Matrix Theory. So, before we begin some general guidelines are let us keep our videos off. I will switch off my video in a minute, I turned it on so you can see me during the first class and turn it off in a minute or two and also keep your microphones muted, this will avoid noise into the class and if you have a question please raise your hand and but if I do not see your hand raised, just unmute yourself and you can start speaking and I will answer your question.

So, before we begin let us maybe discuss the organization of the course. This is a new experience for all of us to attend a class online and so we will probably have to be a bit flexible and make things up as we go along.

(Refer Slide Time: 1:22)

E2-212 (Matrix Theory)

Course Description: In this course, we will study the basics of matrix theory, with applications to engineering. The focus will be two-fold: on the beautiful mathematical theory of matrices, and their use in solving engineering problems.

Course Instructor: Chandra Murthy: SPW1.03, ECE Dept.
Webpage: <https://ece.iisc.ac.in/~cmurthy/doku.php?id=courses%20e2-212-index>

TA: Chirag Ramesh and Nagabhushan S. N.
Office hours: TuW 5-6pm; Problem solving session: Saturday 9-10am.

Grading (Tentative plan):

- Quizzes/assignments: 25%
- Midterm – 1: 16 Nov. 2020, in class. 25%
- Midterm – 2: 28 Dec. 2020, in class. 25%

But roughly this is the outline that I have thought for this course. So, this file itself has been shared with you in the teams, so specifically I will show it to you in my teams. So, if you go to teams, and you click on the class scheme and you go to files and then class materials, then there are two things here one is this file that I am showing you, which is the course outline and the other is the textbook by Horn and Johnson, which is the primary textbook I will be using for this course.

And you will incidentally find posts and other things related to the course out here under posts. And some crucial announcements in the announcements tab so that you can have you can have them all the announcements related to the course in one place.

Final: TBD. 25%

Policy in case you miss an exam:

The only reason you might miss an exam is due to extenuating health reasons. You will need to turn in a letter from a registered medical practitioner in case you miss a test. In case you miss one test, your marks from the other two tests will be used to prorate your marks for the one you missed. In case you miss two or more tests, you might fail the course if you do not drop it.

Homeworks:

Homeworks will be assigned approximately once in two weeks. The homeworks need not be turned in, but we will announce a quiz/assignment approximately every week that will comprise of problems very similar to the homework problems. These assignments will be announced in-class, and you will need to turn in your solution within a specified time period (typically 1-2 hours). We will use the best 10 assignment scores to determine your overall score on the homeworks.

Tentative Course Outline:

S. No.	Topics	# Lectures
1	Fundamental ideas – vector spaces, matrices, determinant, rank, etc.	4
2	Norms, error analysis in linear systems	4
3	Eigenvalues and eigenvectors	3
4	Canonical, Symmetric and Hermitian forms, matrix factorizations	6
5	Variational characterizations, the quadratic form	4
6	Location and perturbation of eigenvectors	4
7	Least-squares problems, generalized inverses	4
8	Miscellaneous topics	3
Total		32

So coming back to the course outline, so this is E2-212 Matrix Theory and in this course basically we will study the basics of Matrix Theory and I will also talk about some applications to engineering. This is the course webpage and typically I will try to mirror all the announcements that are put up on teams on the webpage but just to avoid confusion for you all the announcements related to the course will be available on teams, so that you do not really need to go out.

Looks like I lost internet connection for a few minutes. Can somebody confirm if you are able to hear me now?

Student: Sir, we can hear you now.

Professor: Thank you. So, incidentally if I lose internet connection do not panic just wait, hopefully the internet will resume after a minute or two and I will be able to reconnect with you. So, coming back to the course outline, the two TAs Chirag and Nag Bhushan. Chirag you are here, would you like to say hello?

TA: Yes, sir. Hello everyone, I am Chirag; I will be a TA of your course.

Professor: Nag Bhushan are you around? So, both are excellent students, so you can ask your questions and doubts to them also. There are going to be two office hours, which is going to be Tuesdays and Wednesdays, 5 to 6 pm and problem session, solving session which will be on Saturday 9 to 10 am. So, the formal material of the course will be covered during these classes, these are additional times where you can get some help for your course.

But it is not mandatory to attend these sessions, but of course, if you have doubts this is a good time to get them clarified from the TAs and also the problem solving session, there just will not be enough time to do a lot of problem solving in class for this course and so if you want to see some example problems being solved you should attend the problem solving session.

For the grading of this course I currently have a tentative plan of having two midterms and a final in addition to quizzes and assignments and all four parts will have equal weightage. I am also debating whether to have one midterm and final and have a higher weightage for the quizzes and assignments that depends on how easy it is to administer and grade an exam, so we will decide that in a few weeks' time.

But meanwhile, this is the tentative plan that your quizzes and assignments will be worth 25 percent of your grade and the two midterms and the final will all be worth 25 percent of your grade. Now one thing I realize is that given the pandemic situation, it is necessary to plan for the possibility that some of you may fall sick unfortunately during the time which we have fixed for the exam and so this is going to be my policy.

I do not want to have re-exams and so if you miss an exam because of health reasons, then you do need to submit a letter showing that you were indeed sick and that is why you had to miss a test and in case you miss one test, then your points from the other two tests will be used to prorate your marks for the test you missed.

But if you miss two or more tests then you will get a 0 on the test, the test that you missed and we will prorate based on the tests that you have taken but then your overall grade may be very poor. Homeworks are resigned roughly once in two weeks, these homeworks will not be graded and you do not need to turn them in, but we will have a quiz or assignment approximately once every week, which will have a problem, 1 or 2 problems which are very similar to the homework problems.

These will be announced in class and you will have to turn in your solution within 1 or 2 hours after the class. So, and then there will be a series of assignments. We will choose the best ten course to determine your score on these homeworks. Textbooks, I have listed 4 textbooks here. The first textbook is by Horn and Johnson, it is Matrix Analysis, this is the textbook I will be following fairly closely.

And the other textbooks, depending on the part, for some part of the course I will for example, use Golub and Van Loan, some computational aspects are covered better there and Gilbert Strang is listed because it is a good undergraduate level textbook, so if you find Horn and Johnson a bit difficult, it is a good idea to go back and forth between Horn and Johnson and Gilbert Strang.

There are also a series of very excellent video lectures at an undergraduate level on linear algebra, so I very strongly encourage all of you to take time to go over these video lectures and in fact for the most part I am assuming that you are comfortable with the material in these video lectures. This is a graduate level class, so I will basically summarize things that you should know from your undergraduate linear algebra modules.

Almost every undergraduate program that I am aware of does have a part on linear algebra, so I am assuming that you are aware of this and you are completely clear with it and we will take go forward from there.

TA: Sir, we lost audio again sir.

Student: You mic is muted.

TA: Sir, you are muted.

Professor: I do not know how my mic got muted. How long ago did I get muted?

TA: Just 10 seconds.

Professor: So, I was basically done. I was just saying that the last part is the course outline which you can look at on your own. Those are the topics that we will be covering in the course.

SP
Comm.
- Beautiful mathematics
- Topic of active research
- Solve complex problems/prove powerful results using simple ideas.

What is it about?

Two equations : $Ax = b$; $Ax = \lambda x$

Caution:

- Important to spend time outside class hours from day 1

What is it about?

Two equations : $Ax = b$; $Ax = \lambda x$

Caution:

- Important to spend time outside class hours from day 1
- Class notes are NOT enough
- Solve problems. Sometimes, standard procedures don't work
- Like learning a new language
 - Get comfortable making mathematical arguments

With this prelude, let's begin!

So, the first question to ask is why should we study linear algebra? There are two, there are a few primary reasons that I put here and I had be curious to know, so I guess I have already written the answers here. One obvious reason is that this is required. So, for example, if you are an M. Tech signal processing student, then you have to take Matrix Theory, but it is also useful. I mean, after Calculus and Probability or in addition to Calculus and Probability, this is probably the most useful mathematics that you can possibly learn.

It is also very beautiful and I will try my best to give you a sense of that over the duration of this course and it is a topic of active research in its own right, so building the background in linear algebra, if you are interested in doing research and mathematics, then certainly you need this background to even get started. And finally, it allows you to solve very complex problems you or prove very powerful results using simple ideas.

So, these are some of the reasons why you might want to take this course. So, what is it about? So, finally if I had to distill down the contents of this course down to what it is all about? It is just about these two equations $Ax = b$ and $Ax = \lambda x$. So, from your undergraduate linear algebra, you will recognize $Ax = b$ is what we call a linear system of, system of linear equations.

And the $Ax = \lambda x$ is the eigenvalue eigenvector equation. So, it is really about understanding these two equations and everything that you can say about this pair of equations and that is what this course is all about. So, but then it turns out to, you can actually say a lot about these two equations and what I will, in fact, cover in this course is going to be a small sample of what you can say about these two equations.

It still will not be anywhere near being exhaustive. So, there are a few caveats I want to point out um right off the bat. So one thing is that in any mathematical course during the class when arguments are presented to you, it looks very simple, I can assure you of that or it looks fairly simple and you feel like you understand everything, but it is very important to spend time outside of class from day one.

You should look at the textbook, you should look for other material, you should try to solve problems, the class notes are not going to be enough and when you solve problems you will realize that sometimes standard procedures do not work and problems end up requiring you to look for some special way to handle some corner cases and in some ways it is also like learning a new language where we get comfortable making mathematical arguments.

Now the textbook for this course Horn and Johnson is a graduate level textbook, it is a fairly dense textbook. It is actually not easy to read, but nonetheless it has a very extensive collection of results in the area and one of my goals in this course is to get you to be comfortable with Horn and Johnson because it has so many useful results and tomorrow in your research if you need more advanced results from linear algebra, you should not have to hesitate to open the textbook and look for a result that you could possibly use.

And that comfort is really what I am, that is really my goal is to get you to be comfortable enough for the textbook that you can open it up and look at it whenever you need to.

E2-212 Matrix Theory

Review of basic concepts:

Matrix: Rectangular array of symbols
(real or complex numbers)

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix} \in \mathbb{R}^{m \times n} \text{ or } \mathbb{C}^{m \times n}$$

$A=B$ all entries equal

$A+B$ entry-wise sum

$A=B$ all entries equal

$A+B$ entry-wise sum

λA

Proposition:

$$A+B = B+A$$

$$(A+B)+C = A+(B+C)$$

$$\lambda(A+B) = \lambda A + \lambda B$$

$$(\lambda_1 + \lambda_2)A = \lambda_1 A + \lambda_2 A$$

$$\lambda_1 \lambda_2 A = \lambda_1 (\lambda_2 A)$$

Multiplication:

So, let us begin. So, I will begin with a review of some basic concepts. Again these are concepts that you should already know and so if you are not comfortable with the things that

I am talking about now, then you should check whether this is really a course that you want to take or not. So a matrix is a rectangular array of symbols, in the context of this course it is always going to be real or complex numbers.

So, I can write a matrix a as a collection like this containing a_{11} as its first entry, a_{12} as its second entry, a_{1n} as its n th entry in the first row, a_{21} a_{22} up to a_{2m} , a_{m1} , a_{m2} and a_{mn} in the last row. And so this is what we call an m cross n matrix and we write that this is in the space $\mathbb{R}^{m \times n}$ or $\mathbb{C}^{m \times n}$ if depending on whether these a_{ij} s are real valued or complex valued.

So, always when we write the i is going to represent the row index and j is going to represent the column index. Now, we say $a = b$ if all entry wise all the entries of the two matrices match, so all the entries should be equal. When you do $a + b$ you can only do it if the two matrices are of the same size and it is an entry wise sum of the two matrices; that is the ij th entry of $a + b$ is the ij th entry of a plus the ij th entry of b .

λ is a scalar here, it could be a real or complex number, λ times A corresponds to multiplying every entry of A with this value λ . Here is a simple proposition. $A + B$ is the same as $B + A$ that is matrix addition commutes and it also is also distributive. $A + B + C$ is the same as $A + B + C$. λ times $A + B$ is the same as, you first multiply A by λ , then you multiply B by λ and then add them together.

Also multiplying A by $\lambda_1 + \lambda_2$ is the same as first multiplying A by λ_1 , then multiplying A by λ_2 and then adding these two matrices together, product also this kind of rule applies.

(Refer Slide Time: 16:11)

Multiplication:

$$a = [a_1 \ a_2 \ \dots \ a_n] \in \mathbb{R}^{1 \times n}$$

$$b = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_n \end{bmatrix} \in \mathbb{R}^{n \times 1}$$

$$ab = \sum_{i=1}^n a_i b_i \quad (\text{scalar})$$

Matrix multiplication: $A \in \mathbb{R}^{m \times n}$, $B \in \mathbb{R}^{n \times p}$

$$(AB)_{ij} = A_i B_j$$

$\uparrow$ $\leftarrow$
 i^{th} row j^{th} col.

$i=1, \dots, m$
 $j=1, \dots, p$

- Composition of linear transforms
- n -step transition probs. of Markov

- NOT commutative in general.

Proposition:

$$(AB)C = A(BC)$$

Scalar multiplication:

$$[a_1 \ a_2 \ \dots \ a_n] \in \mathbb{R}^{1 \times n}$$

$$\begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_n \end{bmatrix} \in \mathbb{R}^{n \times 1}$$

$$ab = \sum_{i=1}^n a_i b_i \quad (\text{scalar})$$

Matrix multiplication: $A \in \mathbb{R}^{m \times n}$, $B \in \mathbb{R}^{n \times p}$

$$(AB)_{ij} = A_i B_j$$

$\uparrow$ $\leftarrow$
 i^{th} row j^{th} col.

$i=1, \dots, m$
 $j=1, \dots, p$

- Composition of linear transforms
- n -step transition probs. of Markov chains

- NOT commutative in general.

Proposition:

$$(AB)C = A(BC)$$

$$A(B+C) = AB + AC$$

Matrix multiplication: $A \in \mathbb{R}^{m \times n}$, $B \in \mathbb{R}^{n \times p}$

$$(AB)_{ij} = A_i B_j$$

$\uparrow$ $\leftarrow$
 i^{th} row j^{th} col.

$i=1, \dots, m$
 $j=1, \dots, p$

- Composition of linear transform
- n -step transition probs. of M

- NOT commutative in general.

Proposition:

$$(AB)C = A(BC)$$

$$A(B+C) = AB + AC$$

$$(A+B)C = AC + BC$$

Identity matrix: $I_n = \begin{bmatrix} 1 & 0 & \dots & 0 \\ 0 & 1 & & \\ \vdots & & \ddots & \\ 0 & & & 1 \end{bmatrix}_{n \times n}$

$A \in \mathbb{R}^{m \times n}$, $AI_n = A$, $I_m A = A$.

In general
 $AB \neq BA$

Next, matrix multiplication, so I will start by talking about vector multiplication. So, if you have a row vector a_1 to a_n and a column vector b_1 to b_n , then the product $a \cdot b$ these are two matrices or two vectors that can be multiplied with each other. So, this a is $1 \times n$ and this b is $n \times 1$ and when I multiply them together that is taking the sum of a_i times b_i , i equal to 1 to n and so this is going to be a scalar.

So, with this we can define matrix multiplication. If I have two matrices a is of size m by n and b is of size n by p , then their product is a matrix of size m by p and it is defined such that its i j th entry is equal to the product of the i th row of a with the j th column of b . So, I will write this here, i goes from 1 to m , 1 to row index, so it goes to m and j goes from 1 to p and matrix multiplication is very useful in many contexts.

It is, at this point I must mention that this is a strange way of defining the multiplication of two matrices. So for example, one could have thought of taking matrices of the same dimension and multiplying them element wise or you could think about a matrix product as you take a given, take every entry of matrix a and multiply it by the whole matrix b .

If you do that you will get a matrix when you multiply an m by n matrix with an n cross p matrix, you will end up with a matrix of size m by p by newspaper, so that kind of product it turns out, we will see that later also, it is called a Hadamard product and you take the element wise product of a and b , which can only be done if a and b are of the same size, then that is called the Hadamard product. But this is the usual matrix product as defined here.

It is a strange way of defining matrix multiplication and at this point the only small motivation I can give you, but we will see much more later is that it represents a composition of linear transforms. So, as it turns out a matrix as I defined it earlier is a rectangular array of numbers, but a more useful way to think about a matrix is to think of it as defining a linear transform.

So, a matrix a in of size m by n is essentially defining a transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$ and any linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$ can be represented as a matrix A and if you take that viewpoint, then a matrix product AB actually corresponds to a composition of linear transforms.

So, if you, for example, start with a , from a dimension p space that is we start from $\mathbb{R}^p$ to $\mathbb{R}^n$ then multiplication by b corresponds to take going from $\mathbb{R}^p$ to $\mathbb{R}^n$ and then if you go from $\mathbb{R}^n$ space to $\mathbb{R}^m$ space by using another linear transform a which

is another matrix of size m by n , then the joint effect of taking these two transforms one after the other can be represented by this matrix a times b as defined here.

Another motivation I can give you is we will maybe much later in this course look at Markov Chains and it turns out that if you look at associated with the Markov Chains is something called a transition probability. And a Markov Chain is defined by states s_1 to s_n and the probability that you will end up in state j starting from state i in the next step is represented as a matrix whose entries are p_{ij} .

Now, if I ask what is the probability that i end up in state j starting from state i , but not in one step of the Markov Chain, but after say p steps of the Markov Chain, then it turns out that this corresponds to taking the one step transition probability and multiplying it by itself p times, and that multiplication again is defined in this way as defined here.

So, think about it that this way of matrix, defining matrix multiplication is really not intuitive, but it is useful in a variety of scenarios and that is why we define matrix multiplication this way. By the way among the caveats, there is one thing that I wanted to mention which is that a lot of students I have seen have a tendency to think about 2 cross 2 matrices or 3 cross 3 matrices in order to prove results.

So, when they are faced with a result they would say let me take an example and then they take a 2 cross 2 or a 3 cross 3 matrix and show by example that whatever the statement they want to show is in fact true. Such a proof is not acceptable for this class, what we want is that if a statement does not say that it is valid for 2 cross 2 matrices only, then we have to prove it in the general case.

So, cannot show it in a 2 cross 2 or a 3 cross 3 case and consider that we are done. So, this matrix multiplication as written here is not commutative in general, meaning that in general AB is not equal to BA , in fact, AB may be defined, so here as I have defined it here, A is m by n and B is n by p , so I can define AB , but if m is not equal to p , I cannot even define BA , so in general AB is not equal to BA .

Here is another proposition continuing on AB times a matrix C is the same as A times B times C , in other words which matrices you multiply first and which one you multiply later does not matter but it is important to preserve the order of multiplication that is you cannot switch the order you cannot do, instead of doing AB times C you cannot do C times AB or some other order.

Similarly, A times B plus C is the same as A times B plus A times C and A plus B times C is the same as AC plus BC . Notice that again in all of these we are preserving the order in which we are multiplying the matrices, so A times B plus C is not equal to BA plus CA for instance. Another very important matrix will be using in this course is the identity matrix.

This is denoted by I and if this matrix is n cross m and where there may be room for confusion I may write I_n to denote the n cross n identity matrix, it is the matrix that has 1s along the diagonal and 0s everywhere else. And it has the property that A times the identity matrix, if A is m by n , then A times the n cross n identity matrix is equal to A and the m cross m identity matrix times A is also equal to A .

(Refer Slide Time: 24:57)

Handwritten notes on a digital whiteboard. At the top right is the NPTEL logo. The notes are as follows:

Transpose: A^T $(A^T)_{ij} = A_{ji}$
 A^H $(A^H)_{ij} = A_{ji}^*$ Conjugate transpose Hermitian

Prop.: $(A+B)^T = A^T + B^T$
 $(A^T)^T = A$
 $(AB)^T = B^T A^T \leftarrow \text{Show!}$

Trace: Square $A \in \mathbb{R}^{n \times n}$
 $\text{tr}(A) = \sum_{i=1}^n A_{ii}$ Sum of diag entries.

Prop.: $\text{tr}(A+B) = \text{tr}(A) + \text{tr}(B)$
 $\text{tr}(\lambda A) = \lambda \text{tr}(A)$
 $\text{tr}(A^T) = \text{tr}(A)$
 $\text{tr}(AB) = \text{tr}(BA)$ (compatible matrices)

Handwritten notes on a digital whiteboard, identical to the previous slide. At the top right is the NPTEL logo. The notes are as follows:

A^H $(A^H)_{ij} = A_{ji}^*$ Conjugate transpose Hermitian

Prop.: $(A+B)^T = A^T + B^T$
 $(A^T)^T = A$
 $(AB)^T = B^T A^T \leftarrow \text{Show!}$

Trace: Square $A \in \mathbb{R}^{n \times n}$
 $\text{tr}(A) = \sum_{i=1}^n A_{ii}$ Sum of diag entries.

Prop.: $\text{tr}(A+B) = \text{tr}(A) + \text{tr}(B)$
 $\text{tr}(\lambda A) = \lambda \text{tr}(A)$
 $\text{tr}(A^T) = \text{tr}(A)$
 $\text{tr}(AB) = \text{tr}(BA)$ (compatible matrices) $\leftarrow \text{Show!}$

Two viewpoints of matrices

Transpose, taking the transpose of the matrix, simply switches the rows and columns, so the ij th entry of a transpose is the same as the j th entry of A . We also define the Hermitian of a matrix or the conjugate transpose of a matrix where not only do you switch the rows and columns, so ij becomes ji , also take the complex conjugate of the matrix. So, A plus B transpose is the same as A transpose plus B transpose.

The transpose of A transpose is the same as A and this is an interesting result and something that you can try to show that is if you want to take the transpose of the product of two matrices that is the same as taking B transpose times A transpose. How would you show such a result? You would take an ij th entry of AB transpose and then you would find the ij th entry of A transpose by considering a general matrix A and B whose entries are a_{ij} and b_{ij} respectively and then you show that the ij th entries of these two matrices are matching.

Another function that you can apply on a matrix is you can find its trace, this is for square matrices, so here it is an n by n matrix, so the trace of A is the sum of its diagonal entries, so another related result is that the trace of A plus B is the same as the trace of A plus the trace of B , this is obvious because the diagonal entries will add and so if you want to take the sum of the diagonal entries.

You can first take the sum of the diagonal entries of A and then the sum of the diagonal entries of B and then add them together that is the same as adding the two matrices and then finding the sum of the diagonal entries when you multiply A by a scalar λ then every entry of the matrix gets multiplied by λ and so does all the diagonal entries and therefore trace of λA is the same as λ times trace of A .

When you take the transpose of a matrix that keeps the diagonal entries where they are, it only switches the off diagonal entries, the rows become columns and columns become rows but then the diagonal entries remain the same, so the trace of A transpose is the same as the trace of A . It is not true for Hermitian, because when you take the Hermitian, you are doing the conjugate transpose. So, unless the diagonal entries are real valued the trace of A Hermitian is not necessarily equal to the trace of A .

Trace of AB , so this is another interesting property that the trace of AB is the same as the trace of BA , for comparison matrices meaning matrices for which you can define both AB and BA , but considering that we are looking at square matrices here. When I define trace of AB , I am assuming, I mean notice that if I want to look at trace of AB , it is not necessary that A and B should be square, but AB needs to be square because trace is defined for square

matrices, so AB is square and BA is also square and it is such that you can find it AB and BA are both defined, then in that case you can write $\text{trace of } AB = \text{trace of } BA$.

Again this is something that is worth as a small exercise for you to try to show and once again the way to show such a result is to simply write out what $\text{trace of } AB$ will be in terms of the entries of AB , here entries of A and entries of B , write out what $\text{trace of } BA$ will be in terms of the entries of A and the entries of B and show that these two things will be equal.
