Matrix norms: Properties

So, last time we were discussing norms and matrix norms in particular. Today we will continue our discussion on Matrix Norms.

(Refer Slide Time: 00:24)

Just to recall, matrix norm is a mapping from the space of square matrices \mathbb{R} to the n cross n to the real number line \mathbb{R} and we say that this matrix norm, which is denoted by this symbol with three lines around it, this is a matrix norm if for any A and B in \mathbb{R} to the n cross n , it satisfies these four properties. The first is that it is non-negative.

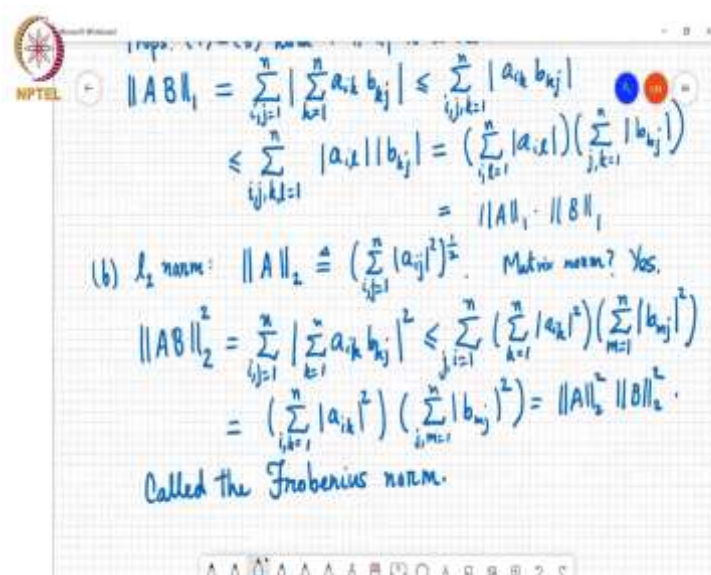

The second is that it is positive, meaning that it can only be equal to 0 if the matrix itself is equal to 0. The third is that it is homogeneous and the fourth is that it satisfies triangle inequality. So basically, any vector norm I start with will satisfy all four of these properties. So, if I think of an n cross n matrix as a big vector containing n squared entries in it and I define a vector norm on that, that will certainly satisfy these four properties.

The only question mark is whether it satisfies this last property, which is called the sub-multiplicativity property or not. So, this is what we will examine today. So, some vector norms are in fact matrix norms when you apply them on \mathbb{R} to the n cross n , whereas others are not. So we will start with the l_1 norm.

So, remember that the l_1 norm of a vector is the sum of the absolute value of all of its entries. If I simply extend that to an n cross n square matrix, then I would define the l_1 norm of a matrix A to be the summation of all of its entries in magnitude. So the question is this a matrix norm or not? So, the answer is, yes.

Of course, this norm as defined here, does satisfy the non-negativity, positivity, homogeneity and triangle inequality by virtue of the fact that it is a l_1 norm in a vector space. So, it directly satisfies those four properties and so we only need to check whether it satisfies this sub-multiplicativity property or not. So, I will just write that here. 1 to 3 hold because it is already a vector norm. So, now about sub-multiplicativity?

(Refer Slide Time: 03:22)

Handwritten mathematical derivation on a grid background:

$$\|AB\|_1 = \sum_{i,j=1}^n \left| \sum_{k=1}^n a_{ik} b_{kj} \right| \leq \sum_{i,j,k=1}^n |a_{ik} b_{kj}|$$

$$\leq \sum_{i,j,k=1}^n |a_{ik}| |b_{kj}| = \left(\sum_{i,k=1}^n |a_{ik}| \right) \left(\sum_{j,k=1}^n |b_{kj}| \right)$$

$$= \|A\|_1 \cdot \|B\|_1$$

(b) l_2 norm: $\|A\|_2 = \left(\sum_{i,j=1}^n |a_{ij}|^2 \right)^{\frac{1}{2}}$. Matrix norm? Yes.

$$\|AB\|_2^2 = \sum_{i,j=1}^n \left| \sum_{k=1}^n a_{ik} b_{kj} \right|^2 \leq \sum_{i,j=1}^n \left(\sum_{k=1}^n |a_{ik}|^2 \right) \left(\sum_{m=1}^n |b_{mj}|^2 \right)$$

$$= \left(\sum_{i,k=1}^n |a_{ik}|^2 \right) \left(\sum_{j,m=1}^n |b_{mj}|^2 \right) = \|A\|_2^2 \|B\|_2^2$$

Called the Frobenius norm.

So, what I need to show is that if I take any two matrices and I find AB , l_1 , this is going to be less than or equal to the l_1 norm of A times the l_1 norm of B , that is what I need to show. Now this quantity $\|AB\|_1$ is the sum of the magnitude of the entries of AB which is equal to $\sum_{i,j=1}^n$. So, this is the sum over all the entries of this product matrix.

But each entry in the product is the inner product between a row and a column of A and B respectively. So, I will write that like this. So if you remember we discussed this different ways of writing out a matrix product. This is the way by which we write out every entry of the product matrix a_{ik} times b_{kj} . This is the i, k th entry of this product matrix AB .

Now this quantity itself, I can upper bound by taking the magnitude inside the summation, this is less than or equal to summation. Now because the summation will go over i, j and k , I

will just write them together $\sum_{j,k=1}^n a_{i,j} b_{k,j}$. This in turn is less than or equal to. What I will do is, say here it is index k and then there is k repeating here, I will just replace this k with an l and take the summation l going from 1 to n as well.

What I am doing there is I am introducing a whole bunch of non-negative terms into the summation and so that can only increase its value, it cannot decrease it. So, I will write this says $\sum_{j,k=1}^n a_{i,j} b_{k,j}$. So, this is a double summation over two indices, just make this a little neater $\sum_{j,k=1}^n a_{i,j} b_{k,j}$.

Now, this is just a , so notice that in the first term, it depends on i and l , it has no j and k in it, the next term has j, k in it, but no i or l . So, this is actually equal to the product of these two terms, $\sum_{l=1}^n a_{i,l}$ times $\sum_{j,k=1}^n b_{k,j}$ and this is nothing but by our definition here, this is nothing but the l_1 norm of a times the l_1 norm of b .

And thus $\|AB\|_1$ is less than or equal to the l_1 norm of A times the l_1 norm of B . So, it satisfies sub-multiplicativity and hence, this $\|A\|_1$ as defined here is indeed a matrix norm. So, we can go to the next possibility. So, we did l_1 now we can look at l_2 .

Student: Sir?

Professor: Yeah.

Student: The notation for matrix norm will have three vertical bars. Why have you ignored the one, one of the bars?

Professor: Yeah, good question. So, it turns out that I am going to define the l_1 matrix norm a little differently in a few minutes. Once we discuss something called induced norms. So, it turns out that this is not quite the definition of the matrix l_1 norm that I am interested in and so I have used a different notation.

So, for these norms that I am discussing here, I will use only two bars to distinguish this norm from another notion of l_1 norm on matrices that I am going to define momentarily.

Student: Okay, sir.

Professor: So, the l_2 norm also, I am going to denote it with two bars, because again, this is not quite the l_2 norm on matrices that I am going to later be interested in. But I will define this to be.

TA: Sir, there is another question.

Professor: Yeah.

Student: Sir, in the previous one, you have written like a_{ik} , b_{ik} and you have introduced a i . So, what does it mean? I mean, for every a_{ik} , you are replacing it with bunch of a_{il} ? I mean, you are adding a i .

Professor: Yeah.

Student: So, a_{ik} and you are adding some other like a_{il} is it?

Professor: Yeah, there are many a_{il} . I am adding n into $n - 1$ terms into the summation, which will only increase its value, but they are all in magnitude. So, none of them is negative. So, it can only increase the value.

Student: I got it, thank you.

Professor: So, the l_2 norm I defined like this. So, it is so just like the vector l_2 norm, which is the square root of the sum of the squares of all the entries, I defined the l_2 norm to be the sum of the squares of all the entries in the matrix and then you take the square root. So, is this a matrix norm.

So once again, by virtue of the fact that it is, this is the l_2 norm of the vectorised version of the matrix. This is this will satisfy the non-negativity positivity, homogeneity and triangle inequality. Again, the only thing we need to look at is whether it satisfies the sub-multiplicativity property or not and again for this norm, it turns out the answer is yes. So, we will see that very quickly.

So, once again if I take the l_2 norm of a product, AB , this is equal to $\sum_{i,j=1}^n$, so I will consider the square so that I do not have to keep writing square roots. So, this AB squared, if I show that this is less than or equal to l_2 norm of A squared times l_2 norm of B squared, that is also good enough for me. So, this is $\sum_{i,j=1}^n$, I have to take a mod square of this term here.

So, I will just write the same term here, $\sum_{k=1}^n a_{ik} b_{kj}$ square and now this is actually the square of the inner product between the i th row of A and the j th column of B and I can use Cauchy Schwarz inequality here and write this as less than or equal to $\sum_{k=1}^n a_{ik}^2 \sum_{m=1}^n b_{mj}^2$. This is just from Cauchy Schwarz inequality.

Then notice that when I take this, if I take this the, if I look at these two terms, this term has a summation over k , but it has no dependence on j and this term has a summation over m but it has no dependence on i . So, I can write this as, this is equal to $\sum_{k=1}^n a_{ik}^2 \sum_{m=1}^n b_{mj}^2$.

These two are exactly equal, just another way of writing this double summation with the summation inside of it and so this is equal to $\|A\|_2^2 \|B\|_2^2$. So, it does satisfy this, sub-multiplicativity property. This particular matrix norm is actually called the Frobenius norm. So, I will maybe mentioned just one property of this norm and the property is that this particular norm is invariant to left or right multiplication by a unitary matrix.

(Refer Slide Time: 14:03)

Called the Frobenius norm.

$$\|A\|_2^2 = \text{tr}(A^T A)$$

Diagram illustrating the trace operation: $\text{tr}(A^T A) = a_{11}^2 + a_{21}^2 + a_{31}^2 + \dots + a_{n1}^2 + a_{12}^2 + a_{22}^2 + a_{32}^2 + \dots + a_{n2}^2 + \dots + a_{1n}^2 + a_{2n}^2 + a_{3n}^2 + \dots + a_{nn}^2$

If $A = [a_1, a_2, \dots, a_n]$

$$\|A\|_2^2 = \|a_1\|_2^2 + \|a_2\|_2^2 + \dots + \|a_n\|_2^2$$

If U is unitary, $\|Ux\|_2 = \|x\|_2$.

Hence, $\|UA\|_2^2 = \|Ua_1\|_2^2 + \|Ua_2\|_2^2 + \dots + \|Ua_n\|_2^2$

$$= \|a_1\|_2^2 + \|a_2\|_2^2 + \dots + \|a_n\|_2^2 = \|A\|_2^2$$

Similarly, can st. $\|UAV\|_2^2 = \|A\|_2^2$ if U, V unitary.

So, one useful trick in this in this direction is that this norm $\|A\|_2^2$ is actually equal to the trace of $A^T A$. So, if you think about the entries of $A^T A$ along the diagonals, you will get the sum of the squares of each column, the entries of each column of A . So, I will because we are doing this online.

I just maybe show you that very easily, very quickly. If I have $a_{11}, a_{12}, a_{21}, a_{22}$ and if I take its transpose and left multiply it, that would be $a_{11} \ a_{21} \ a_{12} \ a_{22}$ and then if I look at the diagonal entries, they will be the first diagonal entries will be a_{11}^2 plus a_{21}^2 . The second diagonal entry will be a_{12}^2 plus a_{22}^2 and so if I take the trace of this matrix, this is $\text{A}^T \text{A}$.

So, if I take the trace of this, this is equal to a_{11}^2 plus a_{12}^2 plus a_{21}^2 plus a_{22}^2 and so it is exactly this Frobenius norm as we defined it here. So, this is one useful formula. Now, what I wanted to say though, is that if you have a matrix A and I write out its columns, a_1 up to a_n , then if I look at what this a_i^2 squared is, this is actually equal to the sum of the squares of all the entries in this matrix.

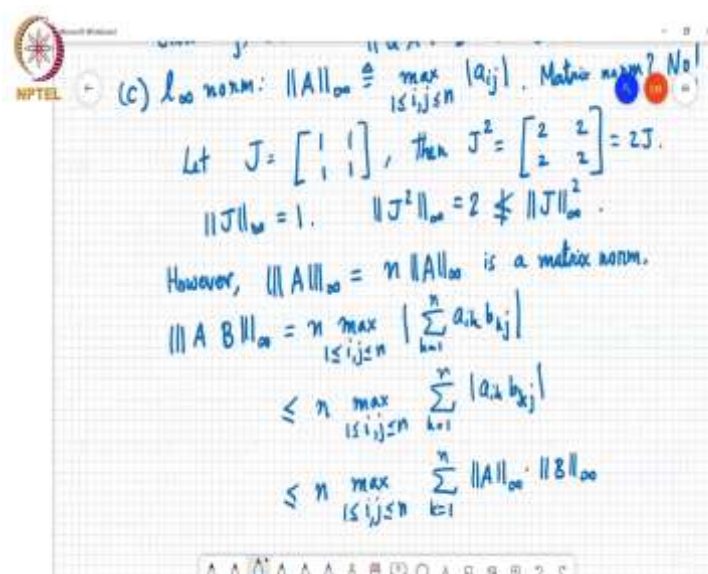

But I can also write that as $\|a_1\|_2^2$ norm squared, which is a sum of the squares of the entries in the first column of A plus $\|a_2\|_2^2$ norm square plus plus $\|a_n\|_2^2$ norm squared. This is another way of writing it. Now, the ℓ_2 norm by itself is unitary invariant meaning that if I have, if U is unitary then $\|\text{U}x\|_2$ norm is equal to the ℓ_2 norm of x itself.

The way to see this immediately is that recall again that the ℓ_2 norm square in the vectors for vectors the ℓ_2 norm square is equal to $x^T x$. So, if I take the ℓ_2 norm of $\text{U}x$ that is equal to $x^T \text{U}^T \text{U} x$ and $\text{U}^T \text{U}$ is the identity matrix. So, that is the same as $x^T x$. So, this is true for any unitary matrix and for the ℓ_2 norm.

So, we have that if I take the ℓ_2 norm of U times A square then that is equal to by using this formula here it is equal to $\|\text{U}a_1\|_2^2$ norm square plus $\|\text{U}a_2\|_2^2$ norm square plus etc plus $\|\text{U}a_n\|_2^2$ norm square. So, now, I am using the column view of matrix multiplication, when I multiply U with a matrix A the columns of the product are equal to the multiplication of U with each of the individual columns of A .

And so this is because this is equal to a_1^2 square plus, this is equal to $\|a_1\|_2^2$ norm of a_1 square, this is equal to the ℓ_2 norm of a_2 square plus etc plus the ℓ_2 norm of a_n square, which is equal to the ℓ_2 norm of A square. So, this Frobenius norm is invariant to left multiplication by a unitary matrix. You can similarly show that if I have, if I take you $\|\text{U} \text{A} \text{V}\|_F^2$ norm square this is equal to $\|\text{A}\|_F^2$ norm square when or I will say if you U, V are unitary. So, basically this Frobenius norm is invariant to left or right multiplication by a unitary matrix.

(Refer Slide Time: 19: 47)

(c) l_∞ norm: $\|A\|_\infty \triangleq \max_{1 \leq i, j \leq n} |a_{ij}|$. Matrix norm? No!

Let $J = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$, then $J^2 = \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix} = 2J$.

$\|J\|_\infty = 1$. $\|J^2\|_\infty = 2 \not\leq \|J\|_\infty^2$.

However, $\|AB\|_\infty = n \|A\|_\infty \|B\|_\infty$ is a matrix norm.

$$\|AB\|_\infty = n \max_{1 \leq i, j \leq n} \left| \sum_{k=1}^n a_{ik} b_{kj} \right|$$

$$\leq n \max_{1 \leq i, j \leq n} \sum_{k=1}^n |a_{ik} b_{kj}|$$

$$\leq n \max_{1 \leq i, j \leq n} \sum_{k=1}^n \|A\|_\infty \|B\|_\infty$$

So, the next thing I want to consider is the l_1 norm and l_2 and l_∞ . So, we are basically covering most of these l_p norms for p not equal to 1, 2 or infinity, it is a little more difficult to figure out what is going on. So, we do not and usually in applications, you do not encounter those norms.

So, we do not worry about too much about those norms. So, this l_∞ norm, if I simply extend the definition, it would be the max $|a_{ij}|$ less than or equal to n , mod $|a_{ij}|$ the l_∞ norm of a vector is the max magnitude entry and so I am extending that and saying the l_∞ norm of a matrix is the max magnitude entry across the matrix. Is this a matrix norm?

So, for this particular example, it turns out that the answer is no. So, there is a, so once again, when you want to show that it is not a matrix, now, all you need to do is to provide one counter example, where it does not work and that is enough. So, if I let the matrix, so if I consider J equal to the all ones 2×2 matrix, then J^2 , what is J^2 equal to it is the $2J$ matrix, which is equal to two times J .

So, if I look at the l_∞ norm of J , as per this definition, it is the max magnitude entry, it is 1, but if I look at the l_∞ norm of J^2 , it is 2 which is not less than or equal to the l_∞ norm of J^2 , this was one of the requirements, I mean this see if sub multiplicativity were to hold, then the l_∞ norm of J^2 must be less than or equal

to the 1 infinity norm of j times the 1 infinity norm of J , which is 1 infinity norm of J squared, but that is equal to 1 here, not bigger than 2 and so, this is as written here.

This is not a matrix norm. However, a slight modification to this norm, if I define, now I am using three bars, to distinguish it from what I wrote about, if I write it to be n times A infinity, n is the dimension of A , if A is an n cross n matrix. This is a matrix norm. So, if I consider, so once again, because it is just a scaled version of a vector norm, the first four properties namely non-negativity positivity, homogeneity and triangle inequality are naturally satisfied by this.

So, the only property we need to check is the sub multiple creativity property. So, if I consider $A B$ infinity, then this is equal to n times the maximum entry in magnitude of the i j th entry of $A B$ and as we wrote above, this is equal to $\sum_{k=1}^n a_{ik} b_{kj}$. Now, first of all, I can, if I read, if I take the modules inside the summation, I cannot decrease the value of the summation.

So, it is less than or equal to $n \max_k |a_{ik}| |b_{kj}|$ less than or equal to n of $\sum_{k=1}^n |a_{ik}| |b_{kj}|$. And that in turn is less than or equal to. So, what I can do is, I can replace all these a_{ik} s with the largest a_{ik} s value the largest magnitude entry in the entire matrix that will only increase the value of this solution, I can replace this b_{kj} s with the largest magnitude entry of the matrix B that will also further only increase the value of this summation.

And so that is less than or equal to $n \max_k |a_{ik}| |b_{kj}|$ less than or equal to n of $\sum_{k=1}^n A$ infinity, where this is the maximum magnitude entry, which is the norm A infinity with two bars as I defined it here times B infinity and now there are n such terms here, so I get an extra factor of n by removing this summation here.

(Refer Slide Time: 25:39)

$\|J\|_{\infty} = 1. \quad \|J^2\|_{\infty} = 2 \neq \|J\|_{\infty}^2.$
 However, $\|A\|_{\infty} = n \|A\|_{\infty}$ is a matrix norm.

$$\|AB\|_{\infty} = n \max_{1 \leq i, j \leq n} \left| \sum_{k=1}^n a_{ik} b_{kj} \right|$$

$$\leq n \max_{1 \leq i, j \leq n} \sum_{k=1}^n |a_{ik} b_{kj}|$$

$$\leq n \max_{1 \leq i, j \leq n} \sum_{k=1}^n \|A\|_{\infty} \cdot \|B\|_{\infty}$$

$$= n \|A\|_{\infty} \cdot n \|B\|_{\infty} = \|A\|_{\infty} \cdot \|B\|_{\infty}.$$

And so this is equal to n times A infinity times n times B infinity which in turn is equal to the norm as I defined here times the norm as I defined here. So, with a small modification to the definition I can get, I can get a definition which is indeed a matrix norm. Any other, Any questions so far.
