## Matric Theory Professor. Chandra R. Murthy Department of Electrical Communication Engineering Indian Institute of Science, Bangalore Lecture No. 04 Linear transforms

(Refer Slide Time: 0:14)

Linear Transforms Say, have U, V VS over a field F. 00 Thus,  $f: U \rightarrow V$  is said to be a linear map if (i)  $f(u_1+u_2) = f(u_1) + f(u_2) + u_1, u_2 \in U$ (ii)  $f(\lambda u) = \lambda f(u) + \lambda \in F$ ,  $u \in U$ .  $(f(a,u,+a,u_2) = a, f(u,)+a, f(u,) + a, a_2 \in \mathbb{F}, u, u, eth)$ . The values taken by f on some basis of U completely determines f. · O always maps to O · Muy A & R man is a linear transform from R -> R" and via versa. AAAAAA M98 ? \* determines f. . O always maps to O. . Any A G R man is a linear transform from R -> R" and via versa. . Matrix multiplication connerponds to a compretition of LTD Sup U has basis  $\{u_1, \dots, u_n\}$   $v_1 = f(u_1), v_2 = f(u_2), \dots, v_n = f(u_n)$ Any  $u \in U$  can be written as  $u = u_1u_1 + \dots + u_n$  un By linearity, f(u) = f(x, u, + ... + x, un) = x, f(u,)+...+x, f(un) 

So, the next topic is Linear Transforms. So, suppose we have u and v, these are two vector spaces over a field f, then a mapping from u to v is said to be a linear map if two conditions hold or a transform if 1, f of u1 plus u2 equals f of u1 plus f of u2 for all u1, u2 in this first vector space and the second is that f of lambda u is equal to lambda f of u for all lambda belonging to this field and u belonging to this set u, vector space v.

So, these are the two conditions that define a linear transform. Often this is written compactly as f of a1, u1 plus a2, u2 is equal to a1 f of u1 plus a2 f of u2 for all a1, a2 in this field f and u1, u2 in this vector space u. But this is just another way of writing it, so you may or may not agree that this is a more compact way, to me this is a slightly more intuitive way of writing it.

Some properties of a linear transform are that the values of f over, on some basis of u completely defines f, that is because every u in this vector space capital U is a linear combination of the basis and f is a linear transform, so if you can write it as a linear combination, then if you know what values f takes on the basis, then you can find its value for any other u that belongs to this vector space capital U.

Second thing is that 0 always maps to 0. So, one way to see it is if you just substitute lambda equals 0 here you have lambda times f of u, whatever f of u is this is 0 and lambda times u is always the 0 vector and, so one very important property is that any A in R to the m by n is a linear transform from R to the n to R to the m and vice-versa.

And another property is that matrix multiplication, this is something I mentioned in the previous class also, matrix multiplication is the corresponds to a composition of linear transforms.

Student: Sir, one doubt this...

Professor: Yes, please tell me.

Student: The previous property you told that the linear transform from Rn to Rm and vice-versa, what is meant by that vice-versa part, means Rm to Rn?

Professor: No.

Student: Can you explain that?

Professor: So, that is a good question. So, any matrix A is a linear transform from Rn to Rm and vice-versa means that any linear transform from Rn to Rm can be represented as a matrix A.

Student: Thank you.

Student: Sir, can you please explain that part again the value taken by f on some basis of u completely determines f?

Professor: So, suppose this u has a basis, u1 through un, and f of un, so suppose I know these n vectors, then any u and capital U as u equal to alpha 1 u1 plus less alpha, and we have seen that this representation is unique, there is a unique linear combination, which gets u to u, when u1 to un is the basis for vector space capital U.

So, by linearity f of u is f of alpha 1 u1 plus alpha n un which is equal to alpha 1 f of u1 plus alpha n f of un, which is equal to alpha 1 V1 plus alpha and Vn, so this is what I mean by saying that the values taken by f on the basis completely determines f on all vectors in capital U. Is it clear?

Student: Yes sir, thank you.

Student: Sir, is there any relation between bases of you, basis of p and the function? Suppose if u and v are of same dimension?

(Refer Slide Time: 9:04)

(1) Range space / cd. space:  $A \in \mathbb{R}^{m \times n}$  $\mathcal{R}(A) = \{y \in \mathbb{R}^{m} | y = Ax, x \in \mathbb{R}^{n} \}$ = Span (Cole of A) Share R<sup>m</sup>  $\dim(\mathcal{R}(A)) \leq \min\{m, n\}$ dim (R(A)) is also called rank of A.  $A = \begin{bmatrix} 1 & 5 & 3 \\ 2 & 4 & 3 \\ 3 & 3 & 3 \end{bmatrix}; \mathcal{R}(A) = Set of LCs of any 2 cds of A$ 

dim ( K(A)) ; R(A) = Set of any 2 c 2 4 3 3 3 3 T Show: R(A) is a subspace of R  $N_1 \in \mathbb{R}^n$ ,  $N_2 \in \mathbb{R}^m$ , can always find  $A \in \mathbb{R}^{m \times n}$  $\Gamma(v) = v$ ETR' and NI, ..., VE E RM, can we A A A A A A A B M Q B ? «

Professor: So, that is what I am going to talk about now, vector spaces associated with a linear transform. So, you might have heard this rank nullity theorem and this is closely related to that, so I am going to talk about that now. Before that maybe I will make a couple of remarks, so one thing is that the way I define this linear transform here, it is a transform from u to v and it satisfies these properties.

Now, it is possible that there are some points in v which are not reachable as f of u for any value of u. What I am trying to say is that the way it is defined here u and v are two arbitrary vector spaces and f of, and not every small v in this vector space capital V needs to be, is required to be reachable by taking f of u for some u in capital U. So, that is one point.

Another point is that as you can see from here, if u has this basis, u1 through un and I take V1 through Vn, then any u in capital U can be written as a linear combination of these vectors and so if I consider only the points that can be, that have an inverse map in capital U, so as I mentioned not every point in capital V needs to have an inverse map small u.

But if I only consider the points in capital V that do have an inverse map small u, that you can show is also a vector space and now that vector space, you can see already that any point in that vector space can be written as a linear combination of V1 to Vn, but now it is not clear that, of course, it is clear that u1 through un are linearly independent. There are basis for capital U, but it is not clear that V1 to Vn are going to be linearly independent.

Moreover any v which is reachable from this vector space u can always be written as a linear combination of V1 to Vn, so V1 to Vn certainly span this set of vectors that are reachable from this set U under this linear map f, but this could be an over complete set; in other words

it is possible that there is a subset of these vectors which span that space but it cannot be more than n.

So, the dimension of the space that can be spanned by this u under this linear map f can be at most n if n is the dimension of u. You cannot increase dimension by using a linear map. But it is possible that you end up decreasing dimension.

Student: So, does this mean that the v is need not be a basis?

Professor: V1 to Vn need not be a basis for the space spanned by u under this transformation f, that is correct.

Student: Thank you.

Professor: So, the first space associated with the linear transform is what is called the range space or the column space. So, now I am going to refer to these linear transforms as matrices because this particular thing is easier stated using matrices. So, and because any matrix can be viewed as a linear transform and any linear transform can be viewed as a matrix, we can also discuss about matrices.

So, range space which is also known as the column space, so that is defined as R of A which is the set of all vectors in R to the m, so let me say A is in R to the m by n, y is equal to Ax, x in Rr to the n. It is the span of the columns of A. It is a subset of R to the m, every vector here belongs to R to the m, in fact, it is a vector space.

Now the dimension of the range space of A is less than or equal to min of m and n. Why is that? Because it is a subspace of R to the m, it is a subset of R to the m so it can have dimension at most m and this matrix A has only n columns and so if you write y equal to Ax with n columns you can have at most n linearly independent vectors in the span of the columns of A. This line of the range space of A is also called what?

Student: Rank of A.

Professor: Exactly, thank you. So, for example, if I have A equal to 1, 2, 3, 5, 4, 3, and 3, 3, 3, 3, then the range space or the column space of A is the set of all linear combinations of any two columns of A. Notice that if I add these two columns and divide by 2, I get the third column, so these three columns are not linearly independent, so only two of them are, any two of them are linearly independent.

So, you can take the first and second, second and third or first and third, any two columns and the set of all linear combinations of those two columns is the range space of A and its dimension is 2, which in this case is actually strictly smaller than the min of m and n, m is 3 and n is also 3 here, this is a map from R to the 3 to R to the 3 and the dimension of or the rank of this matrix A is 2.

So, here is a small thing you should do on your own is actually, maybe I will say a subspace of R to the n, of R to the m, so in other words it satisfies those two properties we discussed the previous class. It is Hotel California, you can never leave, any two vectors in R of A, if you take their sum that also belongs to R of A and if you scale a vector in R of A that also belongs to R of A. Yes, go ahead.

Student: Sir, I have a small confusion. So, given a two pair of vectors or with a different dimension I can always find a matrix A, which will transform let us say vector B to vector A, so then does it mean that I mean a transformation is always linear in nature?

Professor: So, you are saying that given V1 say in R to the n and V2 in R to the m, you can always find A such that V2 equals A V1.

Student: Yes, sir.

Professor: So, that is correct. So, in fact, you can find many such A's, but so what is the point, what is your confusion?

Student: So, my confusion is that is transformations always linear in nature?

Professor: No, what this means is that you can find a linear transform that maps V1 to V2. It does not mean that you can map V1 to V2 and secondly...

Student: There can be some nonlinear transformation, right?

Professor: I do not want to look for that right now, it may not be easy to find a nonlinear transform, here is an example. Suppose I had V1 equal to 1, 2, 3, and V2 equal to 1, 4, 9, now I can always define a transform f of v equal to, I am going to use MATLAB's notation here, dot power 2. What this is doing is it is taking the square of every element in V. This is a non-linear transform which clearly maps V1 to V2. So, it need not be a linear map.

Student: But at the same time we can find matrix A as well to do this transformation, right?

Professor: Yes, in fact, you can find many such matrices because you only have one constraint, you are giving me one point in R to the n and you are giving one point in R to the m and you are asking me to find a matrix A that will map V1 to V2.

Of course, this is going to map other vectors to some other points, but in fact, I can find an A that will map if you give me say, if you give me a set of vectors in R to the n and another set of vectors in R to the m, I can ask is it possible to find an A that will map the first set of vectors one by one to the second set of vectors. So, to answer that question is not immediate from what we have discussed so far.

So, you should keep that question in your mind and revisit it later, so I will write it here, you can think about it later. So, given say u1 through uk in R to the n and V1 through Vk in R to the m can we find a in Rr to the m by n such that vi is equal to A ui, i equal to 1. So, this is a very basic question, but I do not want to answer it right now. It is something to keep in mind and you can revisit it later.

Student: Okay, sir.

Professor: There are conditions under which this is possible and under some conditions it is not possible.

Student: Okay.

Student: Sir, may I ask a question?

Professor: Yes.

Student: Sir, the thing that you told that the element-wise square operation that you showed as an example of nonlinear transformation...

Professor: Yes.

Student: So, if we want to take any V1 and get to any V2 maintaining the relationship that you told that element-wise square, so it is not possible to find any unique A, because A is not a nonlinear, means A cannot be a nonlinear transformation.

Professor: Of course, this kind of nonlinear transform, first of all you cannot express it as multiplying by a matrix A. So, this can never be written as Av, for some matrix A.

Student: Yes, sir. For generality we cannot find any such A.
