Thm. [Fundamental properties of normal matrices]

If $A \in \mathbb{C}^{n \times n}$ has EVals $\lambda_1, \dots, \lambda_n$, the foll. are equivalent:

- (a) A is normal
- (b) A is unitarily diagonalizable
- (c) $\sum_{i,j=1}^n |a_{ij}|^2 = \sum_{i=1}^n |\lambda_i|^2$
- (d) There is an orthonormal set of n EVecs of A .

Recall that matrix is normal if $A A^H$ equals $A^H A$. It commutes with its Hermitian and we saw that it is a generalization of unitary, real symmetric and Hermitian matrices. And we saw a simple 2 cross 2 example of a matrix that is normal but not unitary, Hermitian or skew Hermitian. We also defined unitary diagonalizability. So, a matrix is said to be unitarily diagonalizable if it is unitarily equivalent to a diagonal matrix. So, the similarity transform that will take the matrix to a diagonal matrix is in fact a unitary matrix.

So, this is the theorem which gives us some fundamental properties of normal matrices. So, if the matrix A which is of size n cross n has eigenvalues λ_1 to λ_n then these four properties are equivalent. First is that A is a normal matrix. Second is that A is unitarily diagonalizable. And the third is that the sum of the squares of all the entries of A which is also the Frobenius norm square of the matrix A is equal to the sum of the squares of its eigenvalues. And the fourth is that there is an orthonormal set of n eigenvectors of A that is n has a full set of eigenvectors which are orthonormal to each other.

(Refer Slide Time: 01:53)

Proof: Let $T \in (\nabla)_{n \times n}$ s.t. $U^H A U = T$.

T is unitarily equivalent to A .

(a) is equivalent to normality of T .

$AA^H = A^H A$
 $TT^H = T^H T$

(a) \Rightarrow (b): A normal $\Rightarrow T$ is normal.

$$\begin{pmatrix} \nabla \end{pmatrix} \begin{pmatrix} \nabla \end{pmatrix} = \begin{pmatrix} \nabla \end{pmatrix} \begin{pmatrix} \nabla \end{pmatrix}$$

$T^H \quad T \quad T \quad T^H$

(1,1)th elem: $\Rightarrow t_{11} t_{11}^* = t_{11} t_{11}^* + \sum_{j=2}^n t_{1j} t_{1j}^*$
 $\Rightarrow \sum_{j=2}^n |t_{1j}|^2 = 0 \Rightarrow t_{1j} = 0, j=2, \dots, n.$

(2,2)th elem $\Rightarrow t_{2j} = 0.$

$$\begin{pmatrix} \nabla \end{pmatrix} \begin{pmatrix} \nabla \end{pmatrix} = \begin{pmatrix} \nabla \end{pmatrix} \begin{pmatrix} \nabla \end{pmatrix}$$

$T^H \quad T \quad T \quad T^H$

(1,1)th elem: $\Rightarrow t_{11} t_{11}^* = t_{11} t_{11}^* + \sum_{j=2}^n t_{1j} t_{1j}^*$
 $\Rightarrow \sum_{j=2}^n |t_{1j}|^2 = 0 \Rightarrow t_{1j} = 0, j=2, \dots, n.$

(2,2)th elem $\Rightarrow t_{2j} = 0, j=3, 4, \dots, n$

Proceeding this way, $t_{ij} = 0, j > i, i=1, \dots, n$
 $t_{ij} = 0, j < i, i=1, \dots, n (\because T \nabla)$

$\Rightarrow T$ is diagonal \Rightarrow (b) holds.

So, we will see have to show this. So, if, so the starting point is again Schur's unitary triangularization theorem. So, let T be upper triangular of size n cross n such that U Hermitian A U equals T . So, this means that T is unitarily equivalent to A . That means that this when we say A is normal then that is the same as saying that T must be normal. So, that is something that you can immediately verify that. So, A , normality of A is equivalent to normality of T . So, you can easily check that if A is normal then T is normal. And this is an if and only if condition, so...

Student: Sir.

Professor: Yes, go ahead please

Student: Sir what is normality of A and normality of T?

Professor: Normality is the property that a matrix commutes with its conjugate transpose. So, normality of A is the property that $AA^H = A^H A$. The normality of T is the property that $TT^H = T^H T$. So, if A is normal then T is normal. But T is upper triangular. So, if I look at upper triangular matrix and I write out this condition $TT^H = T^H T$. That looks like this.

So, I will write TT^H . So, T^H would be a lower triangular matrix and T is an upper triangular matrix. T^H , so this is T^H , this is T and that is the same as TT^H . And now if you see what happens when you equate the entries of these two products. What I am going to argue is that if T is normal and upper triangular then it must be diagonal.

So, if I take the 1, 1 element of both the left and side and the right hand side here then what we get is the 1, 1 element of this is going to be $t_{11} \bar{t}_{11}$. And so that will be $|t_{11}|^2$ and the 1, 1 element here would be this column times this row which is $t_{11} \bar{t}_{11}$ plus the summation $j=2$ to n $t_{1j} \bar{t}_{1j}$.

So, now this is $|t_{11}|^2$ and it cancels with this $|t_{11}|^2$. And this is $\sum_{j=2}^n |t_{1j}|^2$. So, this means that $\sum_{j=2}^n |t_{1j}|^2 = 0$, which in turn means that, these are all non negative quantities, so if you add up all of these and you are still getting 0 every one of them must be 0. So, $t_{1j} = 0$, $j=2$ through n .

So, basically other than the 1, 1 element all other entries in the first row must be equal to 0. Similarly if you equate the 2, 2 entry what you will get is that $t_{2j} = 0$ for $j=3, 4$ up to n . And so on. So, just proceeding this way we get $t_{ij} = 0$ for $j > i$ and i going from 1 to n . And of course $t_{ij} = 0$ for $j < i$ and i going from 1 to n because T is upper triangular. So, for all $j < i$ the entries are always equal to 0. So, this means that T is diagonal, which means that A is unitarily diagonalizable.

(Refer Slide Time: 8:35)

$\Rightarrow T$ is diagonal $\Rightarrow (b)$ holds.
 $(b) \Rightarrow (a)$ Diagonal matrices are normal
 Unitary equivalence preserves normality
 $\therefore (b) \Rightarrow (a)$.
 $(b) \Rightarrow (c)$: A unitarily diagonalizable \Rightarrow Diag. entries are λ_i
 Unitary equivalence preserves Frobenius norm.
 $\Rightarrow \sum_{i,j=1}^n |a_{ij}|^2 = \text{tr}(A^H A) = \sum_{i=1}^n |\lambda_i|^2$
 $(\exists \text{ diag. } D \text{ and unitary } U \text{ st } D = U^H A U)$
 $\Rightarrow \sum_{i=1}^n |\lambda_i|^2 = \text{tr}(D^H D) = \text{tr}(U^H A^H U U^H A U) = \text{tr}(U^H A^H A U)$
 $= \text{tr}(A^H A) = \sum_{i,j=1}^n |a_{ij}|^2$.

The other way is actually much simpler. So, T implies A . So, what we need to show is if A is unitarily diagonalizable then A is a normal matrix. So, basically any diagonal matrix is already normal. For any normal matrix D , D Hermitian D just contains mod d_i squared around the diagonals. And so that is equal to $D D^H$ Hermitian for any diagonal. So, all diagonal matrices are normal. And unitary equivalence preserves normality. So, basically therefore b implies a . So, a and b are done.

Now, if you want to show b implies c what we need to show is that if A is unitarily diagonalizable then summation of mod a_{ij} square equals the summation of λ_i square. If A is unitarily diagonalizable then the resulting diagonal matrix will have the eigenvalues λ_i on the diagonal, because I have told it is a similarity transform and if you are using a similarity transform to get a diagonal form then the diagonal entries must be λ_i .

So, and further, I will just show this in a second, unitary equivalence is a property that preserves Frobenius norm. So, that means that $\sum_{i,j=1}^n |a_{ij}|^2$ is equal to the trace of $A^H A$ which is equal to $\sum_{i=1}^n |\lambda_i|^2$. So, to see this, I mean this is simple.

Basically if A is unitarily diagonalizable then there exists a diagonal D containing eigenvalues of A and unitary u such that $D = u^H A u$. And then so then summation of λ_i squared, which is equal to the trace of $D^H D$ which is equal to the trace of, I will substitute for D , $u^H A u$ which is equal to the trace of, this is

just the identity matrix, so $u^H A u$ is Hermitian. And this trace is the similarity invariant and this $u^H A u$ is a similarity transform. And so you have trace of A which is equal to $\sum_{i=1}^n \lambda_i$.

(Refer Slide Time: 13:40)

$(c) \Rightarrow (b): \lambda_i, i=1, \dots, n \text{ are diag. entries of } T.$
 $\Rightarrow \sum_{i,j=1}^n |a_{ij}|^2 = \text{tr}(A^H A) = \text{tr}(u^H T^H u u^H T u)$
 $= \text{tr}(u^H T^H T u) = \text{tr}(T^H T)$
 $= \sum_{i=1}^n |\lambda_i|^2 + \sum_{i,j=1}^n |t_{ij}|^2$
 $\Rightarrow \sum_{i,j=1}^n |t_{ij}|^2 = 0, \quad \begin{matrix} t_{ij} = 0 & i < j \\ t_{ij} = 0 & i > j \end{matrix} \because T \text{ is } \nabla$
 $\Rightarrow T \text{ is diagonal.} \Rightarrow (b).$

To go the other way, so to show the other way, so specifically that we want to show that if summation of λ_i^2 equals summation of λ_i squared then A is unitarily diagonalizable. So, when we use the Schur's triangularization theorem to find a unitary transform such that $u^H A u = T$, λ_i going from 1 to n are the diagonal elements of T or will be the diagonal elements of T . So, that is basically how the eigenvalues are related to the matrix A . So, there exist a u such that $u^H A u = T$ and the diagonal entries of T are these λ_i .

So, basically if somebody told us that summation, so $\sum_{i=1}^n \lambda_i^2$ is equal to $\sum_{i=1}^n \lambda_i$ squared. So, if we were to try to compute this, this is equal to the trace of $A^H A$ which is in turn equal to, I will just write it. so that its clear... Trace of $A^H A$ and I will substitute for u and I will write this as trace of $u^H T^H u u^H T u$, which is equal to trace of $u^H T^H T u$, which is equal to trace of $T^H T$, because trace is unitarily invariant that are invariant to this kind of a similarity transform.

This is a similarity transform on T Hermitian T , and the trace is invariant to similarity transformation, so this is the same as trace of $T^H T$, which I can write since the diagonal

entries are λ_i . So, the trace of T Hermitian T can be written as $\sum_i \lambda_i$, it is the sum of the mod of all the entries in T , mod square of all the entries in T . And I keep the diagonal entries separate, $\sum_i \lambda_i^2 + \sum_{i < j} |t_{ij}|^2$. This, these two, this equality is coming because of c. So, we are assuming c is true and we are trying to show that the matrix must be unitarily diagonalizable.

So, this immediately implies that, or sorry, we put it this way. This, this quantity here and this quantity here are equal because of our assumption that $\sum_{i,j} |t_{ij}|^2 = \sum_i \lambda_i^2$. So, that immediately implies that $\sum_{i < j} |t_{ij}|^2 = 0$ or $|t_{ij}|^2 = 0$ for $i < j$. And of course $|t_{ij}|^2 = 0$ for $i > j$ because T is upper triangular.

So, if the row index is bigger than the column index all these entries are always 0. So, T is diagonal. So, that means that the upper triangular matrix we got by applying a unitary transformation of A through the Schur's triangularization theorem is in fact diagonal. So, which implies that a, matrix A is unitarily diagonalizable which is the statement b.

(Refer Slide Time: 18:45)

Handwritten mathematical proof on a grid background:

$$\begin{aligned} \text{tr}(T) &= \text{tr}(U^H T U) = \text{tr}(T^H T) \\ &= \sum_{i=1}^n |\lambda_i|^2 + \sum_{i < j} |t_{ij}|^2 \\ &\quad \left[\text{Eqn. (c)} \right] \\ \Rightarrow \sum_{i < j} |t_{ij}|^2 &= 0, \quad \begin{matrix} t_{ij} = 0 & i < j \\ t_{ij} = 0 & i > j \end{matrix} \therefore T \text{ is } \Delta \\ \Rightarrow T &\text{ is diagonal. } \Rightarrow (b). \\ (b) \Rightarrow (d): &\exists U \text{ s.t. } U^H A U = \Lambda = \text{diag}(\lambda_1, \dots, \lambda_n) \\ \Rightarrow A U &= U \Lambda \Rightarrow \exists n \text{ orthonormal Evecs of } A. \\ (d) \Rightarrow (a): &\exists n \text{ orthonormal Evecs of } A, A U = U \Lambda \\ \Rightarrow U^H A U &= \Lambda \Rightarrow A \text{ is unitarily diagonalizable. } \square \end{aligned}$$

Then b implies d. So, if A is unitary diagonalizable we want to show that there is an orthonormal set of n eigenvectors of A . So, if A is unitarily diagonalizable then it means there exists a U such that $U^H A U = \Lambda$ which is equal to this diagonal matrix containing λ_1 through λ_n . That so if I take U to the other side or rather multiply U on both sides I will get

$Au = u\lambda$. Or each of these columns of u are actually, so this λ is a diagonal matrix. So, it means that $Au_i = \lambda_i u_i$. Or there exists n orthonormal eigenvectors of A .

And the other way is also exactly the same. If there exists n orthonormal eigenvectors, so if there exists n orthonormal, all these steps are reversible, so basically it follows... of A , then $Au = u\lambda$ where λ is a diagonal matrix containing the eigenvalues of A . So, that implies $u^H Au = u^H u \lambda$, since these eigenvectors are orthonormal $u^H u = I$, or $u^H Au = \lambda$, which equals the identity matrix. So, if I do $u^H Au$, if I multiply u^H on the left then I get $u^H Au = \lambda$ which is a diagonal matrix, so which means that A is unitary diagonalizable.

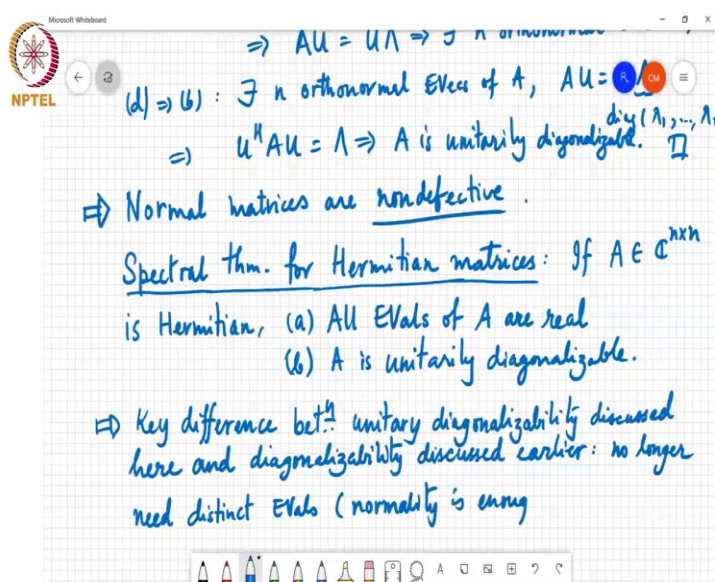

Student: Sir

Professor: Yeah

Student: Sir, these $\lambda_1, \lambda_2, \dots, \lambda_n$, how are they saying that there are distinct always?

Professor: They are not. That is a crucial point actually. So, this is the main, one of the main differences between what we said earlier and what we are saying now. Earlier for diagonalizability one of the conditions was that, one of the sufficient conditions was that the eigenvalues need to be distinct. We do not need that here.

(Refer Slide Time: 21:48)

So, the important consequence of this is that normal matrices are non defective. They are always diagonalizable, and the algebraic multiplicity equals the geometric multiplicity of the matrix. So, we have seen that Hermitian matrices are a special case of normal matrices. If A is Hermitian then it means $A = A^H$. And therefore $A A^H = A^H A$ which is both equal to A^2 .

And so Hermitian matrices are normal and for Hermitian matrices we can say one small extra thing which is known as the Spectral theorem for Hermitian matrices. So, if A in $\mathbb{C}^{n \times n}$ is Hermitian then all eigenvalues of A are what, what can we say about the eigenvalues of?

Student: Real

Professor: Real, exactly. And b, A is unitarily diagonalizable. See this is useful because all covariance matrices are Hermitian symmetric, by definition. Covariance matrix is the expected value of $x x^H$ where x is a vector. And so since covariance matrices are Hermitian symmetrical matrices all eigenvalues of covariance matrix are real and any covariance matrices unitarily diagonalizable. Now, the statement b here immediately follows from the fact that the matrix is, any Hermitian matrix is a normal and a normal matrix we just showed this, that any normal matrix is unitarily diagonalizable.

Now, the point is that the eigenvalues are real follows because if a matrix, any diagonal and Hermitian symmetric matrix must be real. And so, and unitarily, I mean this unitarily equivalence preserves Hermitian symmetry. And so if I find the matrix that it is unitarily equivalent to matrix A and it is diagonal then the matrix T which is unitarily equivalent to A must be Hermitian symmetric as well.

And if it is Hermitian symmetric and diagonal it is the real valued matrix. So, all the eigenvalues are real. Between unitary diagonalizability here and diagonalizability that we discussed earlier which was through similarity transforms is that we no longer need distinct eigenvalues. In other words normality is enough.
