LU Decomposition with Pivoting

(Refer Slide Time: 00:14)

So, the last time we looked at LU decomposition by a gaussian elimination and we outlined the procedure and I also showed you an example and towards the end of the last class I told you about some numerical issues that arise in the LU decomposition.

Namely, that if there is a very small number that appears as a pivot element then inverting that when you compute it using a finite precision machine can lead to incorrect answers.

And so that motivates us to look at LU decomposition with pivoting. So, pivoting is the process by which you try to stabilize the LU decomposition process and the way we do that is through the use of these permutation matrices. So, just very briefly a permutation matrix this, there are many types of permutation matrices but for the purposes of this discussion we will discuss about permutation matrices where a pair of rows or a pair of columns are getting exchanged.

So, we have notation P and π , P is the identity matrix with two rows say row i and j being permuted are exchanged. And π is the identity matrix with columns i and j being permuted or exchanged. Then if you define P and π this way then if you

consider PA for any matrix A it exchanges the i th and j th rows of A and $A\pi$ similarly exchanges the i th and j th columns of A .

(Refer Slide Time: 01:58)

Handwritten notes on a whiteboard:

- π : Identity matrix w/ cols 2 and 3 permuted
- Then: PA : Exchanges rows i & j in A
- $A\pi$: " cols i & j in A
- Other properties of permutation matrices:
 - $P^T = P^{-1}$ real orthogonal
 - The product of permutation matrices is a permutation matrix
 - Exchange permutation: Swapping 2 rows or cols of I_n . $P^2 = I$ or $P = P^T$
- Suppose $(k-1)$ stages of GE are done:
- $A^{(k-1)} = M_{k-1} P_{k-1} \dots M_1 P_1 A \pi_1 \pi_2 \dots \pi_{k-1}$

So, I mean permutation matrices have many properties including these and also so I will just say. Other properties of permutation matrices. So, for example P transpose equals P inverse so it is a real orthogonal matrix and the product of permutation matrices is another permutation matrix. So, and these permutations that I discussed here are called exchange permutations which basically exchanges exactly two rows or two columns of the matrix it involves swapping two rows or columns of the n cross n identity matrix.

And such matrices have the property that P squared equals P A equals identity matrix. So, basically if you exchange two columns and then you exchange them back you get back the original matrix so if you apply P twice with an exchange permutation you will get the original matrix back.

So, P squared is the identity matrix or P equals P transpose because P so this means P is its own inverse but P inverse equals P transpose P transpose for any permutation matrix. So, P equals P transpose for such matrices so in other words if I take the n cross n identity matrix and exchange any two rows or any two columns I will still get a symmetric matrix.

And that matrix is its own inverse that is special property of exchange permutations. So, now to connect this to the gaussian elimination based LU decomposition procedure so like the previous development suppose k minus 1 stages of the gaussian elimination have

been done and we will describe how to proceed with the k th stage and from if you start with k equal to 1 2 up to n minus 1 then you get the entire LU decomposition.

So, suppose k minus 1 stages of gaussian elimination are done that is to say we have got this matrix A_{k-1} which is equal to M_{k-1} earlier I had M_{k-1} all the way down to M_1 times A is what I had as A_{k-1} it was a pre-multiplication by these gauss transforms.

But, now I can, I will have a potential permutation that was done at the k minus 1 stage P_{k-1} all the way up to $M_1 P_1 A$ and then the second stage I may have to do another column exchange that is π_2 up to π_{k-1} . So, these are the exchanges that I have done so far.

So, I have not told you how to do these exchanges but it will become clear as soon as I tell you what exchange will do with the A_{k-1} matrix to get the A_k matrix.

(Refer Slide Time: 06:41)

columns of I_n . $P^2 = I$ or $P^{-1} = P^T$

Suppose $(k-1)$ stages of GE are done:

$$A^{(k-1)} = M_{k-1} P_{k-1} \dots M_1 P_1 A \Pi_1 \Pi_2 \dots \Pi_{k-1}$$

$$= \begin{bmatrix} \overbrace{A_{11}^{(k-1)} \dots A_{1n}^{(k-1)}}^{\text{upper triangular}} \\ \hline 0 \quad \underbrace{A_{22}^{(k-1)} \dots A_{nn}^{(k-1)}}_{n-k+1} \end{bmatrix} \begin{matrix} \} k-1 \\ \\ \} n-k+1 \end{matrix}$$

$$A_{22}^{(k-1)} = \begin{bmatrix} a_{kk}^{(k-1)} & \dots & a_{kn}^{(k-1)} \\ \vdots & \ddots & \vdots \\ a_{nk}^{(k-1)} & \dots & a_{nn}^{(k-1)} \end{bmatrix}$$

To annihilate the 1st col below 1st row of $A_{22}^{(k-1)}$ in a stable way, choose $\tilde{P}_k, \tilde{\Pi}_k$ of size $(n-k+1) \times (n-k+1)$

Now, this matrix by construction has the form it has A_{11} k minus 1 at the top left and this is upper triangular and I have A_{12} k minus 1 and then 0 here and A_{22} k minus 1. And this is k minus 1 rows and this is n minus k plus 1 rows and similarly this is k minus 1 columns and n minus k plus 1 columns.

And now in order to describe what I want to do next I will consider the entries of A_{22} k minus 1. So, let us call them it starts with index k a_{kk} of k minus 1 a_{kn} because this is the first row of A_{22} k minus 1 is the k th row of this matrix A_{k-1} . So, this k minus

1 and a_{nk} of $k-1$ and $k-1$. So, this what we will call the entries of this matrix.

So, basically when I apply M_k what should happen is this entry will remain as it is and everything else below this will become zero. But, we want to do this in a stable way meaning that among all these entries here we want to get the largest magnitude entry and place it as the top left entry.

Because, we are going to be dividing all these entries by that entry and then doing row operations to make zeros appear in the below the, below the diagonal below this entry. So, to annihilate the first column below the first row of $A_{22}^{(k-1)}$ in a stable way choose we will call it \tilde{P}_k and $\tilde{\Pi}_k$ of size $(n-k+1) \times (n-k+1)$.

So basically, the point is that suppose some entry over here is the largest entry then what you have to do is you have to exchange these two rows so that this entry goes up here and then you should exchange these two columns so that that entry ends up over here right. So, if I do one row exchange in one column exchange I can take whatever entry I find to be the biggest and make it appear as the top left entry.

(Refer Slide Time: 10:36)

To annihilate the 1st col below 1st row of $A_{22}^{(k-1)}$ in a stable way, choose $\tilde{P}_k, \tilde{\Pi}_k$ of size $(n-k+1) \times (n-k+1)$ s.t. the top-left entry of $\tilde{P}_k A_{22}^{(k-1)} \tilde{\Pi}_k$ has the largest abs. value among all elements of $A_{22}^{(k-1)}$.

Then find M_k as before. Then we have $\xrightarrow{k \times k, \text{ upper triangular}}$

$$A^{(k)} = M_k P_k A^{(k-1)} \Pi_k = \begin{bmatrix} A_{11}^{(k)} & A_{12}^{(k)} \\ 0 & A_{22}^{(k)} \end{bmatrix}$$

$$P_k = \begin{bmatrix} I_{k-1} & 0 \\ 0 & \tilde{P}_k \end{bmatrix}, \quad \Pi_k = \begin{bmatrix} I_{k-1} & 0 \\ 0 & \tilde{\Pi}_k \end{bmatrix}$$

So, you do this such that the top left entry of $P_k A_{22}^{(k-1)} \Pi_k$ has the largest absolute value among all elements of $A_{22}^{(k-1)}$. Then we find M_k as before. So, we saw the last time that we will find M_k by, it will be a matrix with ones along the diagonal zeros above the diagonal and minus l_k plus one comma k up to minus l_k and

below the main diagonal of the k th column with l_k chosen to be equal to $A_{i,k}$ of k minus 1 divided by $a_{k,k}$ of k minus 1.

So, all this we discussed the previous time so then we will have A_k is equal to $M_k P_k A_k$ minus 1 times p_i which will be of the form A_{11} k which is now k cross k A_{12} and upper triangular 0 and A_{22} k . And of course a P_k is related to this P_k tilde just by slapping on an identity matrix of size k minus 1 like this P_k is equal to I_{k-1} , 0 0 P_k tilde k .

And similarly p_i k is I_{k-1} , 0 0 by tilde k this just ensures that the first k minus 1 rows and columns of A_k minus 1 remain untouched. So, keep in mind that the exchanges are happening over entries columns and rows of A_k so this when I multiply this P_k times A_k minus 1 it is going to exchange rows of A_k minus 1 but it will exchange rows starting from the k th row up to the n th row it will not touch the first k minus 1 rows of A_k minus 1.

And similarly write multiplying by p_i k will exchange columns starting from the k th column to the n th column it would not touch the first k minus 1 columns of A_k minus 1. So, we will come back to that point later so I will put a star over here. So, this is basically fine so we can execute this and at the end what will happen is that since A_k is of this upper triangular form if I do n minus 1 steps of this kind of thing I will get an upper triangular matrix out here.

So, but then I need to still show that this matrix which is the pre-multiplying matrix is of the form l which is a lower triangular matrix so that when I do when I pre multiply by l inverse then I get a is equal to $L u$ where L is a lower triangular matrix and this u that I have over here is an upper triangular matrix. So, we still need to discuss how that matrix will end up becoming lower triangular.

(Refer Slide Time: 16:02)

$A^{(k)} = M_k P_k M_{k-1} P_{k-1} \dots M_1 P_1 A \pi_1 \pi_2 \dots \pi_k$

Using $P_i^2 = I$,

$$A^{(k)} = M_k P_k M_{k-1} \underbrace{(P_k P_k)}_I P_{k-1} M_{k-1} P_{k-1} P_k P_{k-1} P_{k-2} M_{k-2} \dots$$

$$\dots P_2 M_1 (P_2 P_2 \dots P_k P_{k-1} \dots P_2) P_1 A \pi_1 \pi_2 \dots \pi_k$$

$$= M_k \cdot P_k M_{k-1} P_k \cdot P_k P_{k-1} M_{k-2} P_{k-1} P_k \cdot P_k P_{k-1} P_{k-2} M_{k-3} P_{k-2} P_{k-1} \dots$$

$$\dots P_2 M_1 P_2 \dots P_k \cdot P_k P_{k-1} \dots P_2 P_1 A \pi_1 \pi_2 \dots \pi_k$$

Let $M'_i = P_k P_{k-1} \dots P_{i+1} M_i P_{i+1} \dots P_k$

So in the kth stage what we have is A_k is equal to I am just copying from here $M_k P_k$ but A_{k-1} itself is $M_{k-1} P_{k-1} A_{k-2}$ which is $M_{k-2} P_{k-2}$ etcetera so this keeps going so I have $M_k P_k$ and $k-1$ P_{k-1} all the way down to $M_1 P_1 A$.

And then there is a P_k but when I substitute for A_{k-1} I would have got $M_{k-1} P_{k-1}$ all the way down to $M_1 P_1 A$ $P_1 P_2$ all those things will follow. So, this $P_1 P_2$ up to P_k . So, this is the structure of A_k this is how it is obtained now because these P_i are exchange matrices we have that P_i^2 is equal to the identity matrix so using this we have A_k is equal to I will still keep $M_k, M_k P_k$ and then M_{k-1} .

What I will do is before I write P_{k-1} I will write $P_k P_k P_{k-1}$. So, $P_k P_k$ is the identity matrix and then I have M_{k-1} and so on all the way down to so maybe just to illustrate this thing I will just write one more term here so this will be clear.

So, there is $P_k P_k$ times so this is the identity matrix, so this is the identity matrix P_{k-1} and then I have M_{k-1} and then instead of writing $M_{k-2} P_{k-2}$, I will write $P_{k-1} P_k$ then I will multiply again by $P_k P_{k-1}$ and then I will write P_{k-2} and so on.

So, what I am doing here is notice that this has this structure $P_{k-1} M_{k-1} P_{k-1}$ and then I have P_k sorry if I combine this together as well then I get this form $P_k P_{k-1} M_{k-1} P_{k-1} P_k$. Here, I have $M_k P_{k-1} P_k$ and then

the next term will be P^k minus, $P^k P^{k-1} P^{k-2}$, M^{k-3} and then there will be a $P^{k-2} P^{k-1} P^k$ so all of this things becomes like a symmetric product.

And so this will go all the way down to just before the last term I will have like a $P^2 M^1$ then instead of writing $M^1 P^1 A$, I will write it as $P^2 P^3$ up to P^k times $P^k P^{k-1} P^{k-2} P^{k-1} A$. And then I still have my $\pi_1 \pi_2$ up to π_k . So, I will just rewrite this so that it is clear how I am splitting this product. So, I will write this as M^k times these three times together $P^k M^{k-1} P^k$ times $P^k P^{k-1} M^{k-2} P^{k-1} P^k$ times just one more term for the sake of completeness $P^k P^{k-1} P^{k-2} M^{k-3} P^{k-2} P^{k-1} P^k$ and so on.

And down, all the way down to the last term will be $P^2 M^1$ times $P^2 P^3$ up to P^k times $P^k P^{k-1}$ down to $P^1 A$ and I still have π_1 by π_k . And so now what I will do is I will let M_i dash be equal to

Student: Sir.

Professor: Yeah.

Student: In the first line where you wrote A_k after $(())(22:19)$ how P^k times P^k is coming because at that place P^{k-1} is there so it maybe P^{k-1} times P^{k-1} that is.

Professor: No see I can insert a p^k times p^k wherever I want, it is the identity matrix. So, I am inserting it here.

Student: Okay, got it sir.

Professor: So, $P^k P^{k-1}$ up to P^{i+1} times $M_i P^{i+1}$ up to P^k . So, I will define this to be m_i dash.

(Refer Slide Time: 23:13)

$$A^{(n-1)} = M_k P_k P_{k-1} \dots P_{i+1} M_i P_{i+1} \dots P_k A \Pi_1 \Pi_2 \dots \Pi_k$$

$$= M_k \cdot P_k M_{k-1} P_k \cdot P_k P_{k-1} M_{k-2} P_{k-1} P_k \cdot P_k P_{k-1} P_{k-2} M_{k-3} P_{k-2} P_{k-1} P_k \dots$$

$$\dots P_2 M_1 P_2 P_3 \dots P_k \cdot P_k P_{k-1} \dots P_2 P_1 A \Pi_1 \Pi_2 \dots \Pi_k$$

Let $M'_i = P_k P_{k-1} \dots P_{i+1} M_i P_{i+1} \dots P_k$

then, after $(n-1)$ stages,

$$A^{(n-1)} = M'_{n-1} M'_{n-2} \dots M'_1 P A \Pi = U$$

where $P = P_{n-1} P_{n-2} \dots P_1$
 $\Pi = \Pi_1 \Pi_2 \dots \Pi_{n-1}$

$$k=n-1:$$

$$M'_i = P_{n-1} \dots P_{i+1} M_i P_{i+1} \dots P_{n-1}$$

$$M'_{n-1} = M_{n-1}$$

$$M'_{n-2} = P_{n-1} M_{n-2} P_{n-1}$$

$$\vdots$$

$$\times P_{i+1} \dots P_{n-1}$$

Then after n minus 1 stages what we have is that A^{n-1} which is an upper triangular matrix is equal to $M_{n-1} \dots M_{n-2} \dots$ all the way down to M_1 times. So, I have all this together till here that will give me M_1 and this product which will be $P_{n-1} \dots P_1$ I will call that P and then this is A and then this product π_1 through π_{n-1} I will call that π .

And this is an upper triangular matrix U . P is equal to $P_{n-1} P_{n-2} \dots P_1$ and π equals π_1 .

Student: Sir.

Professor: Yes.

Student: Sir, in A^{n-1} should not and $A M_{n-1}$ be multiplied because in A_k there was M_k being multiplied.

Professor: Can you say that again what is the question?

Student: In A_k sir the term is $M_k P_k M_{k-1} P_k$ so in A^{n-1} there should be an A , M_{n-1} there right?

Professor: There will be an M_{n-1} correct. So, you are right it will be M_{n-1} and that is why M_{n-1} is defined to be so I think you can, I understand your confusion so if I want, so in the, so notice that the first so this thing is true for i being

less than k . At i equals k these matrices would not be there I cannot go to so if I take, oops, yeah so let us maybe clarify this point, oops.

So, if I take if I take k equal to n minus 1 because I want A n minus 1 so then I will write over here k equal to n minus 1 then I have M_i dash is equal to P n minus 1 all the way up to P i plus 1 times M_i times P i plus 1 all the way up to P n minus 1. And so notice that if I take i equal to n minus 1 then I will get M_{n-1} dash and I have M_{n-1} here but this should be P n minus 1 plus 1 which is P n . but, there is no matrix P n that we are using in this process so these matrices will not be there for the M n minus 1 dash.

So, M n minus 1 dash is actually equal to M n minus 1 there is no matrices multiplying these. But, if I take M n minus 2 dash that is going to be equal to P n minus 1 M n minus 2 P M n minus 1 and so on. Does that clarify your question?

Student: Yes sir, thank you sir.

(Refer Slide Time: 28:28)

Assume $M'_{n-1} M'_{n-2} \dots M'_1 = L^{-1} = \text{Lower \(\Delta\)} \text{ular}$

$\Rightarrow \boxed{LU = PA^T}$

Suffices to show that M'_i is unit Δ

$M_i = \begin{bmatrix} 1 & & 0 \\ & \ddots & \\ 0 & x & \\ & & \ddots & \\ & & & 0 & 1 \end{bmatrix}$

$P = \begin{bmatrix} 1 & 0 & 0 & 0 \\ a & 1 & 0 & 0 \\ b & 0 & 1 & 0 \\ c & 0 & 0 & 1 \end{bmatrix}$

P : Exchanges rows of M_i w/ rows $> i$

largest abs. value among ...
 then find M_k as before. Then we have $k \times k$, upper triangular

$$A^{(k)} = M_k P_k A^{(k-1)} \Pi_k = \begin{bmatrix} A_{11}^{(k)} & A_{12}^{(k)} \\ 0 & A_{22}^{(k)} \end{bmatrix}$$

$$P_k = \begin{bmatrix} I_{k-1} & 0 \\ 0 & \tilde{P}_k \end{bmatrix}, \quad \Pi_k = \begin{bmatrix} I_{k-1} & 0 \\ 0 & \tilde{\Pi}_k \end{bmatrix}$$

k^{th} stage:

$$A^{(k)} = M_k P_k M_{k-1} P_{k-1} \dots M_1 P_1 A \Pi_1 \Pi_2 \dots \Pi_k$$

$$P_i^2 = I,$$

$$A^{(k)} = M_k P_k M_{k-1} (P_k P_k) P_{k-1} M_{k-1} P_{k-1} P_k P_k P_{k-1} P_{k-1} M_{k-2} \dots$$

$$\dots P_2 M_1 (P_2 P_2 \dots P_k P_k P_{k-1} \dots P_2) P_1 A \Pi_1 \Pi_2 \dots \Pi_k$$

Professor: So, basically what we have then is so we have this product of all these matrices that times $PA \pi$ is an upper triangular matrix. So, for a moment let us assume $M_{n-1} \dots M_2 M_1$ is equal to L inverse and which is a lower triangular matrix.

Just for a moment imagine that this is true I will show you why this is true in a minute but assume that this is lower triangular. Then what we have is if I multiply by L inverse or if I multiply by L on both sides then I will have L times u is equal to P times A times π . So, it is an LU decomposition not of A but it is the LU decomposition the product of L and u gives you a row and column permuted version of A .

But, I still need to show that this product is going to be lower triangular. Now, the point is that if each of these matrices were lower triangular then of course their product would also in fact they are all matrices which we defined the original M_k s that we defined had were unit lower triangular.

So, we will end up showing that these matrices are also unit lower triangular. So, it is sufficient to show that M_i is unit lower triangular and the, but then this is simple because these permutation matrices like I mentioned at that star the permutation matrices only touch the rows and columns corresponding to so in the $k-1$ th stage they will only exchange rows and columns corresponding to the $A_{22}^{(k)}$ part that is they are not touching the top $k-1$ cross $k-1$ entry.

So, in other words so for example if you take the original M_i if you remember the original M_i was of this form, was of this form where I had ones along the diagonal but in

the k so M_i right so i th column so in the i th column I had a 1 here and then I had some let me just go back here in my notes yeah it was minus L_k plus 1 or L_i plus L_i like that.

I plus 1 comma it is too difficult to write so I will just say here the sum star here and some star here whatever these entries were non-zero only below this thing everywhere else it was zeros but only these entries were non-zero. And now what I am doing in the k th stage is that I am applying an exchange matrix which is exchanging rows and columns corresponding to this part of the matrix.

So, if I exchange rows and columns corresponding to this part then let us see so what happens is that P matrix so let us see, so let me put it this way suppose I take this matrix with ones along the diagonal and then non-zeros only here. So, maybe it is even easier if I take a slightly more concrete thing so let me write it as $1 \ a \ b \ c$ and then $0 \ 1 \ 0 \ 0 \ 0 \ 1 \ 0$ and $0 \ 0 \ 0 \ 1$.

And suppose I had exchanged some two rows let is say these two rows and then say, so I need to bring the largest element to the top left so what yeah so it will be, it would not be like this. So, I have to look at A_{22} of k minus 1 and I will be trying to bring the largest element over here.

So, the exchange will be of the form where I would exchange maybe these two rows and then I have to exchange some pair of columns but of course I am trying to bring it bring the largest entry over here so maybe it is an exchange of these two columns. Now, if I exchange these two rows what will happen is I will get b okay let us write that $b \ 0 \ 1 \ 0$ out here and then $a \ 1 \ 0 \ 0$ here and then $1 \ 0 \ 0 \ 0$ here and $c \ 0 \ 0 \ 1$ here.

And now let is say I exchange these two columns then I will end up with yeah so I will put this here 1 if I exchange these two columns I will end up with no this is not how you go one second this is not correct.

Let me write it in a different way. So, the P matrix it exchanges rows of M_i with I think I understood the point is that M_i dash is yeah so I, yeah my example was what I was doing was not correct. So, maybe we will come back to that with rows greater than I and so basically let me let me put it like this. Suppose, I start with this matrix $0 \ 0 \ 0 \ a \ 1 \ 0 \ 0 \ b \ 0 \ 1$ 0 and $c \ 0 \ 0 \ 1$.

Then remember that the M_i dash is obtained by doing $P A$, $P M_i$ times P_i so if you go back here notice that the core structure is something like this P_i plus 1 M_i P_i plus 1 that kind of thing and P_i plus 1 is going to exchange rows in M_i corresponding to some pair of rows which are greater than i . So basically, what you do is here in this structure what it will do is you pick two rows the it is the same matrix P_i and P_i plus 1 that is going on the left and right.

(Refer Slide Time: 37:32)

Handwritten notes on a Microsoft Whiteboard:

P : Exchanges rows of M_i w/ rows $> i$

Suppose P_{i+1} exchanges rows $k, m > i$

Then $P_{i+1} M_i P_{i+1}$ is the same as M_i , but with elements L_{kx} and L_{mx} exchanged.

$P_{i+1} M_i P_{i+1}$ is unit Δ .

All M_i are unit Δ

L^{-1} is unit $\Delta \Rightarrow L$ unit Δ .

Two matrices are shown:

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ b & 0 & 1 & 0 \\ a & 1 & 0 & 0 \\ c & 0 & 0 & 1 \end{bmatrix}$$

Arrows indicate the exchange of rows 2 and 3, and columns 2 and 4.

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ c & 0 & 1 & 0 \\ b & 0 & 0 & 1 \\ a & 0 & 0 & 1 \end{bmatrix}$$

So, suppose you exchange these two columns then you will also be exchanging the first and third column you will be exchanging the first and third row.

If I do this let is see what happens when I exchange the first and third row I will get $b \ 0 \ 1 \ 0$ $a \ 1 \ 0 \ 0$ and $1 \ 0 \ 0 \ 0$ and $c \ 0 \ 0 \ 1$ here and now if I exchange these two columns then this column appears here. I will have so I still have the same just a second what am I doing wrong here?

I have to correct myself again anyway let us see so the exchange is going to be among rows of M_i with indices greater than i so this part is not going to get touched, it is going to be a pair of rows and columns among these. So, if I take let is say these two rows and I exchange them then let is see what I get I will get a matrix $1 \ 0 \ 0 \ 0$ $c \ 0 \ 0 \ 1$ and then $b \ 0 \ 1 \ 0$ and $a \ 1 \ 0 \ 0$.

And now, I have to exchange the same columns because it is P_i plus 1 M_i P_i plus 1. So, I have to exchange the same second and fourth column of this matrix if I exchange these two then what I will get is the matrix $1 \ c \ b \ a \ 0 \ 1 \ 0 \ 0 \ 0 \ 1 \ 0$ and $0 \ 0 \ 0 \ 1$ exactly. So, this

is the idea so all that happened by this $P_{i+1} M_i P_i$ is that the entries a and c got exchanged.

Otherwise, the structure is exactly retained so that is the basic idea here. So, for example suppose P_{i+1} exchanges rows l and m which are both greater than i then $P_{i+1} M_i P_i$ is the same as M_i but with elements l and m exchanged, so, this is a bad notation because I had written l and m to be the entries of this matrix M_i but anyway it is l and m so let me say this is M_i' .

Then l and m are exchanged. Or in other words this matrix $P_{i+1} M_i P_i$ is unit lower triangular and that means that all M_i' are unit lower triangular and this means that L^{-1} is unit lower triangular which implies that L is also unit lower triangular.

So, that completes this discussion to say that this process even with pivoting gives you an LU decomposition not of A but of PA where P is a permutation, P and P_i are permutation matrices.
