Eigenvalues: Majorization theorem and proof

(Refer slide Time: 0:15)

$(B_r)_{ij} = u_i^H A u_j, \quad B_r \in \mathbb{C}^{r \times r}$
 If EVs of A and B_r are arranged in $\uparrow$ order,

$$\lambda_k(A) \leq \lambda_k(B_r) \leq \lambda_{k+n-r}(A), \quad k=1, 2, \dots, r$$

Proof: If $r < n$, choose $(n-r)$ additional vecs $u_{r+1}, \dots, u_n$ s.t.
 $\{u_1, \dots, u_n\}$ are an orthonormal set. $U \triangleq [u_1, \dots, u_n] \in \mathbb{C}^{n \times n}$.
 U is unitary $\Rightarrow \text{Evals}(U^H A U) = \text{Evals}(A)$
 $\Rightarrow B_r$ is a principal submatrix of $U^H A U$, obtained by
 deleting the last $(n-r)$ rows and cols. Now use prev. result. $\square$

Some of the eigenvalues. So, there is a close connection or appears to be a close connection between the diagonal entries of a matrix and the eigenvalues. What is the precise relationship between these two? Or can we be a bit more specific, other than saying that they are both real valued and they have the same sum, can we be more specific about the relationship between these two sets of real numbers and this notion is what is called majorization. So, we will define this notion now.

(Refer Slide Time: 0:49)

$\Rightarrow B_r$ is a principal...
 deleting the last $(n-n)$ rows and cols. Now use prev. result.

Defn. [Majorization]: Let $\alpha \in \mathbb{R}^n$ and $\beta \in \mathbb{R}^n$ be given.
 If their elements are arranged in increasing order:
 $\alpha_{j_1} \leq \alpha_{j_2} \leq \dots \leq \alpha_{j_n}$
 $\beta_{m_1} \leq \beta_{m_2} \leq \dots \leq \beta_{m_n}$
 and if $\sum_{i=1}^k \beta_{m_i} \geq \sum_{i=1}^k \alpha_{j_i} \quad \forall k=1, 2, \dots, n$
 and if equality is satisfied at $k=n$, then
 β is said to **majorize** α .

By the way, the word majorization also appears in the context of optimization, but that is a different notion do not get confused this is a notion of majorization that we are defining here in linear algebra. So, let alpha in $\mathbb{R}^n$ and Beta in $\mathbb{R}^n$ be given. If their elements are arranged in increasing order meaning that alpha j_1 less than or equal to alpha j_2 less than or equal to less than or equal to alpha j_n .

So, these are the indices where the j_1 is the index in alpha for which the corresponding entry in alpha has the smallest value and j_n is the index for an entry in alpha where the corresponding entry of alpha has the largest value and similarly beta. So, beta say m_1 less than or equal to beta m_2 less than or equal to beta m_n and if the summation i equal to 1 to k beta m_i is greater than or equal to sigma i equal to 1 to k alpha j_i for every k equal to 1, 2, up to n and if equality is satisfied at k equal to n , then beta is said to majorize alpha.

The vector beta majorizes alpha in the sense that it is, we say that beta is kind of greater than or equal to alpha, if the sum of the k smallest entries in beta is greater than or equal to the sum of the k smallest entries in alpha. And this holds for k equal to 1, 2 all the way up to n minus 1, and the sum of the entries are equal.

NPTEL

$\begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \end{bmatrix}$ majorizes $\begin{bmatrix} 0 \\ 1 \\ 2 \\ 7 \end{bmatrix}$; $\begin{bmatrix} 3 \\ 1 \\ 2 \end{bmatrix}$ majorizes $\begin{bmatrix} 2 \\ 7 \\ 0 \end{bmatrix}$

Thm. $A \in \mathbb{C}^{n \times n}$ Herm. The vec. of diag entries of A majorizes the vec. of Evals of A .

Proof: Induction. $n=1$ nothing to prove.
 Suppose the result holds for all $A \in \mathbb{C}^{k \times k}$, $k \leq n-1$.
 Let $A \in \mathbb{C}^{n \times n}$ Herm. be given.
 Let $A_1 \in \mathbb{C}^{(n-1) \times (n-1)}$ be obtained by deleting the row & col of A corresp. to its largest diag. entry.

NPTEL β is said to majorize κ .
 Ex. $\begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \end{bmatrix}$ majorizes $\begin{bmatrix} 0 \\ 1 \\ 2 \\ 7 \end{bmatrix}$; $\begin{bmatrix} 4 \\ 3 \\ 1 \\ 2 \end{bmatrix}$ majorizes $\begin{bmatrix} 2 \\ 7 \\ 0 \end{bmatrix}$.

Thm. $A \in \mathbb{C}^{n \times n}$ Herm. The vec. of diag entries of A majorizes the vec. of Evals of A .

Proof: Induction. $n=1$ nothing to prove.
 Suppose the result holds for all $A \in \mathbb{C}^{k \times k}$, $k \leq n-1$.
 Let $A \in \mathbb{C}^{n \times n}$ Herm. be given.
 Let $A_1 \in \mathbb{C}^{(n-1) \times (n-1)}$ be obtained

So, for example, this vector 1, 2, 3, 4 majorizes 0, 1, 2, 7. So, this number is bigger than this number, 1 plus 2 is 3 is bigger than 0 plus 1, 1 plus 2 plus 3 is 6 is greater than 0 plus 1 plus 2, which is 3. But the sum of all these guys is 10. And the sum of all these guys is also equal to 10.

So, equality is met when you add up all the entries together. But I do not need these to have been arranged in increasing order like this. If I had written it like this 4, 3, 1, 2 this majorizes. And I do not need this to have been written in increasing order 1, 2, 7, 0. I can write it like this also. So, these two vectors, but of course, it is possible that two vectors that have the same sum still do not majorize each other.

This is a very special structure not all vectors can be ordered like this. So, this is the notion of majorization. So, we have the following result. So, A is in C to the n cross n Hermitian. Then the vector of diagonal entries of A majorizes the vector of eigenvalues of A . That means that if I take the smallest diagonal entry of A , that will still be greater than or equal to the smallest eigenvalue of A , if I take the sum of the two smallest diagonal entries of A that will be greater than or equal to the sum of the two smallest eigenvalues of A and so on. So, let us quickly prove this.

So, you can see this is very interesting and again what I consider a very counter intuitive result. That you will be able to find such a very interesting relationship between the diagonal entries of A matrix and the eigenvalues of A matrix. So, the proof goes by induction. So, induction meaning will look at the size of the matrix and use induction over the size of the matrix. When I take n equals 1 the if you take a scalar that is equal to the diagonal entry is also equal to the eigenvalue and so there is nothing to prove.

Now suppose this result holds for all matrices of size k cross k and k going up to n minus 1. I know we need to show that the result holds for k equal to n . Now, we need to show that this result holds for n . So, A be a n cross n matrix. We are given matrix. Now, consider the matrix A_1 which is obtained by deleting a row and column and for A_1 this result holds by our induction hypothesis, how do I get A_1 .

I get it by be obtained by deleting the row and column. Corresponding to its largest diagonal. So, find out which is the largest diagonal entry of A and that row and column I delete and I call the matrix A_1 . So, now if you are (())(09:46), you are already seeing how this proof will go. So now the A_1 is obtained by deleting a row and column and so we will use the interlacing result.

(Refer Slide Time: 09:57)

$\lambda_1 \leq \dots \leq \lambda_n$ be the Evals of A
 $\lambda'_1 \leq \dots \leq \lambda'_{n-1}$ " " " " A_1
 $a_{i_1 i_1} \leq a_{i_2 i_2} \leq \dots \leq a_{i_n i_n} : \text{diag}(A).$
 By the induction hypothesis, $\sum_{i=1}^k a_{ijij} \geq \sum_{j=1}^k \lambda'_j, k=1, \dots, n-1$
 By the interlacing thm, $\lambda_1 \leq \lambda'_1 \leq \lambda_2 \leq \lambda'_2 \leq \dots \leq \lambda'_{n-1} \leq \lambda_n.$
 $\sum_{j=1}^k \lambda'_j \geq \sum_{j=1}^k \lambda_j, k=1, \dots, n-1$
 $\Rightarrow \sum_{j=1}^k a_{ijij} \geq \sum_{j=1}^k \lambda_j, k=1, \dots, n-1$
 And = holds at $k=n \because \text{trace} = \sum \text{Evals}.$ $\square$

So let $\lambda_1 \leq \dots \leq \lambda_n$ be the eigenvalues of A and $\lambda'_1 \leq \dots \leq \lambda'_{n-1}$ be the eigenvalues of A_1 . Now, by the induction hypothesis. First of all, let us say $a_{i_1 i_1} \leq a_{i_2 i_2} \leq \dots \leq a_{i_n i_n}$ be the diagonal entries of A .

We obtained A_1 by deleting the row i_n , row and column of the matrix A . Now, by the induction hypothesis $\sum_{i=1}^k a_{ijij} \geq \sum_{j=1}^k \lambda'_j$. So, the diagonal entries arranged in increasing order of the matrix A is the same as the diagonal entries of the matrix A_1 arranged in increasing order. So, I can write a_{ijij} here.

This is greater than or equal to $\sum_{j=1}^k \lambda'_j$ and this is true for k equal to 1 through $n-1$ this is just directly from the induction hypothesis. Now, from the interlacing theorem, we have that $\lambda_1 \leq \lambda'_1 \leq \lambda_2 \leq \lambda'_2 \leq \dots \leq \lambda'_{n-1} \leq \lambda_n$.

So, that means that if I am taking the first k guys here. Instead, if I add a λ_1 through λ_k , I will get a each of these $\lambda'_1 \geq \lambda_1, \lambda'_2 \geq \lambda_2$ and so on. So, I can write $\sum_{j=1}^k \lambda'_j \geq \sum_{j=1}^k \lambda_j$ and this is true for k equal to 1 all the way up to $n-1$.

And so, this inequality continues to hold with λ_j this summation j equal to 1 to k λ_j sitting here. So, $\sum_{j=1}^k a_{ij} i_j$ is greater than or equal to $\sum_{j=1}^k \lambda_j$. And this is true for k equal to 1 through n minus 1. But equality certainly holds because the trace equals the sum of the eigenvalues. So, that is it.

So, the what we have shown is that the vector of diagonal entries of a matrix A majorizes the vector eigenvalues of a matrix A and this, we use this interlacing property. It is an essential ingredient in showing such results.

(Refer Slide Time: 14:39)

And = holds at $k=n \because \text{trace} = \sum \text{evals.}$

Recall: $\lambda_k(A) + \lambda_1(B) \leq \lambda_k(A+B) \leq \lambda_k(A) + \lambda_n(B)$

If $B \geq 0$, $\lambda_k(A) \leq \lambda_k(A+B)$

$\lambda_{j+k-n}(A+B) \leq \lambda_j(A) + \lambda_k(B).$

Thm. $A, B \in \mathbb{C}^{n \times n}$ Herm.

Let $\lambda(A) = [\lambda_i(A)]$, $\lambda(B) = [\lambda_i(B)]$.

$\lambda(A+B) = [\lambda_i(A+B)]$ denote col vecs in $\mathbb{R}^n$

w/ components = evals of $A, B, A+B$ arranged in $\uparrow$ order

Now, majorization is actually very useful in expressing the relationship between the eigenvalues of the sum of a matrix and the individual components. So, for example, if you recall, we have seen results like λ_k of A plus λ_1 of B is less than or equal to λ_k of A plus B is less than or equal to λ_k of A plus λ_n of B .

So, the k th eigenvalue of the matrix A plus B is at least equal to the k eigenvalue of A plus the smallest eigenvalue of B and at most equal to the k th eigenvalue of A plus the largest eigenvalue of B and if B is positive semi definite then this is non-negative, so, we have λ_k of A is less than or equal to λ_k of A plus B and you also have that λ_j plus k minus n of A plus B is less than or equal to λ_j of A plus λ_k of B .

So, these are some results that we have seen earlier. So, in this context we have two more results that am just going to state because we do not have time to do the proofs right now, but these are

results that talk about majorization type relationships between eigenvalues of the summands to the eigenvalues of the sum of the of two matrices. So, the first result is the following.

So, A, B are n cross n Hermitian symmetric matrices So, let λ of A be a vector and its entries are λ_i of A and λ of B be the another vector whose entries are λ_i of B . Similarly, λ of A plus B is a vector with λ_i of A plus B as its entries and so, these denote column vectors in $\mathbb{R}$ to the n with components equal to the eigenvalues of A B and A plus B arranged in increasing order. This is very important. They are arranged in increasing order.

(Refer Slide Time: 17:56)

Then the vector λ of A plus B majorizes λ of A plus λ of B and so, that is one result. So, it talks about more precise relationship between the eigenvalues of A plus B and the eigenvalues of A and the eigenvalues of B , but what you have to do is to arrange the eigenvalues of A and B in increasing order and then add them together then this vector of eigenvalues of A arranged in increasing order majorizes the vector of λ of A plus λ of B then we also have the following Converse result.

So, let n be at least equal to 1 and let a_1 less than or equal to a_2 less than or equal to up to a_n and λ_1 less than or equal to λ_2 λ_n . So, imagine that these are some diagonal entries and these are some eigenvalues and suppose that this vector majorizes vector λ which has λ_i as its entries then there exists a real symmetric matrix A equal to a_{ij} being its

entries in R to the n cross n such that a_{ii} equal to a_i , i equal to 1 to n . So, it has a_i as its diagonal entries. And λ_i is the set of eigenvalues of A .

So, given a set of numbers real numbers, which where one set of real numbers, majorizes the other set of real numbers then you can find a matrix A such that the vector A are the contains, the vector A forms diagonal entries of this matrix and the vector λ forms the eigenvalues of this matrix. So, there is always such a matrix that you can find. So, that is all I wanted to say today. We will continue on Monday.
