E2 212 Matrix Theory
Jan. 11, 2021.

Last time: Hoffman Wielandt thm:
 $A, E \in \mathbb{C}^{n \times n}$, A & $A+E$ normal.
 $\lambda_1, \dots, \lambda_n$ Evals of A ; $\hat{\lambda}_1, \dots, \hat{\lambda}_n$ Evals of $A+E$.
Then, \exists a permutation $\sigma(i)$ of integers $1, 2, \dots, n$
s.t. $\sum_{i=1}^n |\hat{\lambda}_{\sigma(i)} - \lambda_i|^2 \leq \|E\|_2^2$.

Today: Singular Value Decomposition

The last time we saw the Hoffman Wielandt theorem, which said that if A and E are matrices such that both A and A plus E are normal matrices and if λ_1 through λ_n are Eigen values of A and $\hat{\lambda}_1$ through $\hat{\lambda}_n$ are Eigen values of A plus E then there is a permutation of the Eigen values of A plus E such that each Eigen value of A plus E is close enough to the corresponding Eigen value of A in the sense that the sum of the squares of these differences is at most the spectral norm squared of E .

(Refer Slide Time: 00: 55)

S.V. $\sum_{i=1}^n |\lambda_{\sigma(i)}|^{-1} = \dots$

Today: Singular Value Decomposition

Rectangular matrices: $A \in \mathbb{C}^{m \times n}$
 - Linear map: $\mathbb{C}^n \rightarrow \mathbb{C}^m$

Lemma: $A \in \mathbb{C}^{m \times n}$. Then EVals ($A^H A$) are non-negative.

Proof: $A^H A v = \lambda v \Rightarrow \underbrace{v^H A^H A v}_{\text{real, } \geq 0} = \underbrace{\lambda v^H v}_{\text{real, } > 0} \Rightarrow \lambda \geq 0. \square$

Defn. $A \in \mathbb{C}^{m \times n}$. The singular values (SVals) of A are $\sigma_1, \dots, \sigma_n$, where $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n \geq 0$ and $\sigma_1^2, \sigma_2^2, \dots, \sigma_n^2$ are the EVals of $A^H A \in \mathbb{C}^{n \times n}$. $\text{rank}(A) = \text{rank}(A^H A)$

$\sigma_1, \dots, \sigma_n$, where $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n \geq 0$ and $\sigma_1^2, \sigma_2^2, \dots, \sigma_n^2$ are the EVals of $A^H A \in \mathbb{C}^{n \times n}$.

Lemma: $A \in \mathbb{C}^{m \times n}$. Then $\text{rank}(A) = \text{rank}(A^H A) = \text{rank}(A A^H)$.

Proof: Exercise.

Remark: If $\text{rank}(A) = r$, $r \leq \min(m, n)$, then the first r SVals of A will be > 0 & all of the others will be $= 0$.

Remark: If $A \in \mathbb{C}^{n \times n}$, λ is a nonzero Eval of $A^H A$ iff λ is a nonzero Eval of $A A^H$.

Remark: A and A^H have the same set of nonzero SVals, but if $m \neq n$, one of them will have more zeros occurring as SVals.

Theorem (Th. Singular Value Decomposition)

So, today we start on another topic, which is the singular value decomposition. So, far we have focused our attention on square matrices. So, now, we start discussing about rectangular matrices. Suppose, so basically these are matrices where of size m by n and m may not be equal to n . So, one can view this as a linear map from the \mathbb{C} to the n space to the \mathbb{C} power m space that is it maps an n dimensional vector to another m dimensional vector in the complex space.

We have a few sort of preliminary or precursor lemmas and then we will go to the main theorem. Now, there is one thing I want to mention, which is actually not here. So, remember that when

we will be working with the induced spectral norm that is specifically A_2 which is the max over $\|x\|_2 = 1$ of $\|Ax\|_2$. Now, we know that induced norms satisfy sub-multiplicativity.

Now, when it comes to, so, this is for square matrices we had defined this for square matrices, but we can always define something like this for rectangular matrices also. Because after all you can compute the Euclidean norm of any vector and Ax is a vector only thing is that this constraint space is over the space C to the n or x belongs to C to the n whereas, the objective is being evaluated on a vector that is sitting in C to the m .

So, it is perfectly okay to define the norm A_2 to be a quantity like this even if the matrix A is rectangular. Now, we know that these induced norms satisfy the sub-multiplicativity property and that extends also to rectangular matrices. So, specifically this kind of norm it satisfies the property that $\|AB\|_2$ is less than or equal to $\|A\|_2$ times $\|B\|_2$, of course, here A and B are matrices that can be multiplied together.

So, for example, this could be m by n and this could be n by k or something, then this is still true where these norms are evaluated as given above. So, this is one property and this is easy to show it prove lies is exactly the same as the proof of the, we showed our result that said that induced norms satisfied the sub-multiplicativity property and the proof of this is exactly the same.

Now, a few other precursor lemmas that we need that so, if A is an m by n matrix, then the Eigen values of a Hermitian A are always non negative. We know this already, but anyway the proof is just one line, if A Hermitian A times v equals λ times v simply pre multiply by v Hermitian you get with v Hermitian A Hermitian Av equals λ times v Hermitian v but λ is just a scalar.

And this is just the $\|v\|_2^2$ norm squared of Av and this is the $\|v\|_2^2$ norm squared of v and both are therefore, real and non-negative and these are Eigen vector, it is a non-zero vector. So, this is actually strictly positive. So, this means that λ see this is real this is also real value and so λ cannot suddenly become complex values. So, λ is, and both are non negative. So, λ is real valued, and it is non negative.

So, now we formally defined the singular values of a matrix. So, take rectangular matrix A and the singular values, which I will abbreviate as S vals of this matrix A denoted by σ_1 through

σ_n , where these are ordered in that σ_1 is the largest singular value and σ_n is the smallest singular value.

So, I am indexing it by the number of columns here and σ_1^2 through σ_n^2 are the Eigen values of $A^H A$. So, this is the crucial point here, that σ_1^2 squared up to σ_n^2 , these are the eigenvalues of $A^H A$ and we already saw that these Eigen values are non negative, so I can take the positive square root and that gives me what the singular values are completely defines the singular values.

Now, another lemma is that, if A is of size m by n , then rank of A is the same as rank of $A^H A$. So, $A^H A$ is of size n cross n and $A A^H$ is of size m cross m . So, rank of A is at most $\min(m, n)$ and it is also equal to the rank of this n cross n matrix and it is also equal to the rank of this m cross m matrix I will show this, it is actually very easy to prove, first of all, rank of a matrix rank of AB is at most the rank of A and the rank of B .

So, from that, you get an inequality that says rank of A is rank of $A^H A$ is less than or equal to rank of A and then to show the reverse inequality, then, what you do is you start with $A^H A v = 0$ and if that is true then $v^H A^H A v = 0$ or in other words, $\|Av\|^2 = 0$ that $v^H A^H A v$ is nothing but norm of Av squared. And if that is equal to 0, it means Av must be equal to 0.

So, the null space of $A^H A$ is therefore contained in the null space of A , then you use the rank nullity theorem, you should write this out for yourself, but it is not difficult result to show. And I have a few remarks. If the rank of A is equal to r as a consequence of this, if rank of A is r then the first r singular values of A will be positive and all the other singular values will be equal to 0.

So, the rank of the matrix determines how many non-zero singular values you will have and if A is a square matrix, it is a size n cross n , then λ is a non-zero Eigen value of $A^H A$ if and only if λ is a nonzero Eigen value of A as well. And finally, if A and A^H they have the same rank and they also have the same set of non-zero singular values, if m is not equal to n , then one of them will have more zeros occurring as singular values.

So, these are some small remarks and you can actually relate to these after we go through the SVD theorem.

(Refer Slide Time: 09:17)

Remark: A and A^H if $m \neq n$, one of them will have more zeros occurring as SVals.

Theorem (The singular value decomposition)
 $A \in \mathbb{C}^{m \times n}$. Let $\sigma_1, \sigma_2, \dots, \sigma_r$ be the nonzero SVals of A , where $r = \text{rank}(A)$, and $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r > 0$. Let D be the $r \times r$ diag. matrix w/ $\sigma_1 \dots \sigma_r$ on the diagonal. Let $\Sigma \in \mathbb{R}^{m \times n}$ w/ D as the top left $r \times r$ block and zeros everywhere else. Then, \exists unitary $U \in \mathbb{C}^{m \times m}$ and unitary $V \in \mathbb{C}^{n \times n}$ s.t. $U^H A V = \Sigma$.

Proof

Rectangular matrices: $A \in \mathbb{C}^{m \times n}$
 - Linear map: $\mathbb{C}^n \rightarrow \mathbb{C}^m$

Lemma: $A \in \mathbb{C}^{m \times n}$. Then EVals ($A^H A$) are non-negative.

Proof: $A^H A v = \lambda v \Rightarrow \underbrace{v^H A^H A v}_{\text{real, } \geq 0} = \underbrace{\lambda v^H v}_{\text{real, } > 0} \Rightarrow \lambda \geq 0$

Defn. $A \in \mathbb{C}^{m \times n}$. The singular values (SVals) of A are $\sigma_1, \dots, \sigma_r$, where $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r \geq 0$ and $\sigma_1^2, \sigma_2^2, \dots, \sigma_r^2$ are the EVals of $A^H A \in \mathbb{C}^{n \times n}$.

Lemma: $A \in \mathbb{C}^{m \times n}$. Then $\text{rank}(A) = \text{rank}(A^H A) = \text{rank}(A A^H)$.

Proof: Exercise.

So, here is the singular value decomposition theorem. What I like about this theorem is that it applies to any rectangular matrix, there is absolutely no structural assumptions being made. So, A can be any m by n matrix and let σ_1 through σ_r be the non-zero singular values of A where r is equal to the rank of A and suppose the singular values are ordered, so that σ_1 is greater than or equal to et cetera greater than or equal to σ_r , which is strictly greater than 0 because there r non-zero singular values.

Let D be a D cross D sorry r cross r diagonal matrix with σ_1 through σ_r along the diagonal and zeros everywhere else and Σ is a matrix of size m by n with D as its top left r cross r block and zeros everywhere else, then you can find a unitary U of size m by m and a unitary V of size n by n such that $U^H A V$ equals Σ this diagonal matrix, but it is not a square diagonal matrix is a diagonal matrix of size m by n and it has σ_1 through σ_r or as its top left r cross block and zeros everywhere else.

So, that is what this theorem says. So, will theorem.

Student: So, what is the difference between Eigen value and singular value?

Professor: So, you can see that here from the definition and we will discuss that a little more later. But the singular values of a matrix squared are the eigenvalues of $A^H A$ Hermitian A , for now, this is the relationship that we have seen. General if since we are discussing rectangular matrices, you cannot talk about Eigen values of A , Ax is not in the same space, it is of size m , whereas x is of size n .

So, you cannot write an equation like $Ax = \lambda x$ if A is of size m by n . But if A is a square matrix, we will see what the relationship between the singular values and the Eigen values of $A^H A$. But for now we are discussing rectangular matrices and so we cannot write a direct relationship between I mean Eigen values are not even defined for a rectangular A .

But when I take a matrix $A^H A$ that is a square matrix and I can define Eigen values for it and the Eigen values are all non-negative and if I denote them by σ_1^2 up to σ_n^2 , then σ_1 through σ_n will be the singular values of A that is the definition that is just directly the definition.

Student: Sir.

Professor: Go ahead please.

Student: Can we say that the singular values are the positive roots of the Eigen values of $A^H A$.

Professor: That is right. That is exactly what we are saying here that if I denote the eigenvalues of $A^H A$ Hermitian A , which are all non-negative by σ_1^2 through σ_n^2 , then

σ_1 is the positive root of those Eigen values of A Hermitian A σ_2 is the positive root positive square root of the second largest Eigen value of A Hermitian A and so on.
