Couette Flow Model

In lecture 32 we looked at Stefan flow model which is essentially a diffusion model to be applied to stagnant surroundings and therefore, momentum equation was not invoked. Only the species transfer and the energy equations were invoked. We applied these equations to the 3 types of mass transfer or 4 types of mass transfer that we normally encounter. There is **a one is** the inert mass transfer without heat transfer, inert mass transfer with heat transfer, then mass transfer with heat transfer and simple chemical reaction and then finally, we applied it to the case of mass transfer with arbitrary chemical reactions. All these four types almost described the overall problem of mass transfer.

Today, we are going to consider the Couette flow model and therefore, we shall be invoking both the momentum equation and continuity equation along with the species transfer and the energy equation.

(Refer Slide Time: 01:39)

So, we shall apply the Couette flow model to mass transfer with wall suction and blowing. This is essentially a case of, let us say, air flowing over surface and air itself is being sucked or blown through the wall which would be the simple case of suction and blowing that we considered even with similarity solutions.

Then we will move to the general problem of convective mass transfer and in this, we shall interpret the effective mass transfer coefficient which we shall term as g^* and by way of an example we will calculate, estimate, the evaporation slash burning time of a liquid droplet.

(Refer Slide Time: 02:34)

Reminder of Gov Eqns - L32($\frac{1}{12}$)

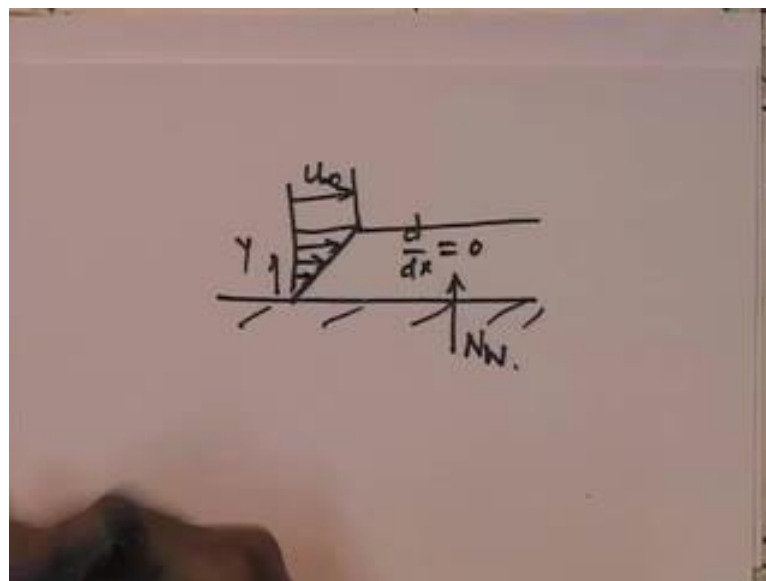

In the Couette flow model, $u = \text{const} \times y$, $(d/dx) = 0$ and $A = \text{const}$. Hence, under steady state

$$\frac{d}{dy} [N_{\psi,y}] = \frac{d}{dy} \left[\rho_m v \psi - (\Gamma + \Gamma_t)_v \frac{d\psi}{dy} \right] = S_\psi$$

Ψ	Γ_Ψ	S_Ψ
1	0	0
u	$\mu + \mu_t$	0
ω_k	$\rho_m (D + D_t)$	R_k
Γ_{k_s}	$\rho_m (D + D_t)$	0
h_m	$(k_m + k_{m,t})/cp_m$	$-d(\sum m_{y,k} h_k)/dy$

where \dot{Q}_{rad} is neglected and $m_{y,k}'' = -\rho_m D (d\omega_k/dy)$. Also, $\rho_m V A = \dot{m}_m = \text{const}$.

(Refer Slide Time: 03:21)

So, let us begin then with the momentum transfer with wall suction and blowing. Now, in the Couette flow model as you will recall, the velocity u is taken to be constant multiplied by y and all actual derivatives are set to 0 and therefore A is constant. Under steady state [transport/transfer] equation would read like this: d by dy of $N_{\psi,y}$ equal to d by dy of $\rho_m v \psi$ minus γ plus γ_t , where γ_t is the turbulent exchange coefficient; $d \psi$ by dy equal to S_ψ just by way of the reminder that the Couette flow model **is really** let us say, this is the surface. We assume that the velocity

profile will be like. So, with u infinity here all d by dx are 0 for all variables and u infinity remains constant along the plate and this is the direction y .

(Refer Slide Time: 03:46)

Reminder of Gov Eqns - L32($\frac{1}{12}$)

In the Couette flow model, $u = \text{const} \times y$, $(d/dx) = 0$ and $A = \text{const}$. Hence, under steady state

$$\frac{d}{dy} [N_{\psi,y}] = \frac{d}{dy} \left[\rho_m v \psi - (\Gamma + \Gamma_t)_{\psi} \frac{d\psi}{dy} \right] = S_{\psi}$$

ψ	Γ_{ψ}	S_{ψ}
1	0	0
u	$\mu + \mu_t$	0
ω_k	$\rho_m (D + D_t)$	R_k
T_k	$\rho_m (D + D_t)$	0
h_m	$(k_m + k_{m,t})/cp_m$	$-d(\sum m_{y,k} h_k)/dy$

where Q_{rad} is neglected and $m''_{y,k} = -\rho_m D (d\omega_k/dy)$. Also, $\rho_m V A = \dot{m}_m = \text{const}$.

So, this is really the Couette flow model; the mass transfer would be taking place in this direction. If you look at the meanings of ψ , ψ equal to 1 would imply simply continuity equation or mass conservation equation, ψ equal to u will imply momentum equation with γ equal to μ and then if it is a mass transfer mass fraction ω_k this would be the species transfer equation and this would be the energy equation.

We have ignored the radiation and other heat generation terms here; $\dot{m}_{y,k}$ is really the Fick's law of diffusion flux given by the Fick's law and $\rho_m V A$ will be \dot{m}_m which is equal to constant which is a mass flux would remain constant.

(Refer Slide Time: 04:39)

Momentum Transfer - 1 - L33($\frac{2}{12}$)

• For $\Psi = u$,

$$\frac{d}{dy} \left[N_w u - (\mu + \mu_t) \frac{du}{dy} \right] = 0$$

Integrating once and noting that $u = 0$ at $y = 0$ and $(\mu + \mu_t) (du/dy)|_{y=0} = \tau_w$, the constant of integration $C = -\tau_w$. Hence,

$$\int_0^\infty \frac{du}{N_w u + \tau_w} = \int_0^\delta \frac{dy}{\mu + \mu_t} = C_1 \quad \text{say}$$

$$= \frac{1}{N_w} \ln \left[1 + \frac{N_w U_\infty}{\tau_w} \right]$$

• But,

$$\frac{N_w U_\infty}{\tau_w} = \frac{\rho V_w U_\infty}{\tau_w} = \frac{V_w / U_\infty}{C_{f,x}/2} = B_r \quad (\text{Blowing Parameter})$$

(Refer Slide Time: 04:47)

Reminder of Gov Eqns - L32($\frac{1}{12}$)

In the Couette flow model, $u = \text{const} \times y$, $(d/dx) = 0$ and $A = \text{const}$. Hence, under steady state

$$\frac{d}{dy} [N_{\psi,y}] = \frac{d}{dy} \left[\rho_m v \Psi - (\Gamma + \Gamma_t)_v \frac{d\Psi}{dy} \right] = S_\psi$$

Ψ	Γ_ψ	S_ψ
1	0	0
u	$\mu + \mu_t$	0_v
ω_k	$\rho_m (D + D_t)$	R_k
h_k	$\rho_m (D + D_t)$	0
h_m	$(k_m + k_{m,t}) / cp_m$	$-d(\sum m_{y,k} h_k) / dy$

where \dot{Q}_{rad} is neglected and $m_{y,k}^v = -\rho_m D (d\omega_k / dy)$. Also, $\rho_m V A = \dot{m}_w = \text{const}$.

(Refer Slide Time: 04:51)

Momentum Transfer - 1 - L33($\frac{2}{12}$)

• For $\Psi = u$,

$$\frac{d}{dy} \left[N_w u - (\mu + \mu_t) \frac{du}{dy} \right] = 0$$

Integrating once and noting that $u = 0$ at $y = 0$ and $(\mu + \mu_t) \left(\frac{du}{dy} \right)_{y=0} = \tau_w$, the constant of integration $C = -\tau_w$. Hence,

$$\int_0^\infty \frac{du}{N_w u + \tau_w} = \int_0^\delta \frac{dy}{\mu + \mu_t} = C_1 \quad \text{say}$$

$$= \frac{1}{N_w} \ln \left[1 + \frac{N_w U_\infty}{\tau_w} \right]$$

• But,

$$\frac{N_w U_\infty}{\tau_w} = \frac{\rho V_w U_\infty}{\tau_w} = \frac{V_w / U_\infty}{C_{f,x}/2} = B_f \quad (\text{Blowing Parameter})$$

Let us consider momentum transfer. If psi is equal to u, then the governing equation remember, there is no source term here but the pressure gradient is also 0 and therefore the equation will be d by dy $N_w u$ minus μ plus μ_t du by dy equal to 0. If I integrate this once and note that the boundary condition is u equal to 0 at y is equal to 0, the shear stress is given by μ times du by dy y equal to 0 of course μ_t would be 0 at the wall. The constant of integration C will be simply minus τ_w and hence the integrating from 0 to infinity would give me du divide by $N_w u + \tau_w$ equal to 0 to δ dy $\mu + \mu_t$ which I am for the moment calling it as constant C_1 - some integrated value C_1 and the integration of this term would simply result in 1 over N_w \ln $1 + N_w U_\infty$ infinity by τ_w .

But what is $N_w u_\infty$ by τ_w ? We can interpret that; remember, N_w is ρ times V_w because the same air, same fluid is being blown into the boundary layer as is flowing over a plate $\rho V_w U_\infty$ divided by τ_w . If I multiply and divide this by U_∞ then, I would get V_w divide by U_∞ equal to ρU_∞^2 by τ_w which is nothing but V_w by U_∞ $C_{f,x}$ by 2 and as you will recall this is nothing but the blowing parameter which we had invoked during similarity solutions and integral solutions.

(Refer Slide Time: 06:41)

Momentum Transfer - 2 - L33($\frac{3}{12}$)

- Therefore, $\ln(1 + B_f) = C_1 N_w = C_1 \rho U_\infty B_f (C_{f,x}/2)$
- As $B_f \rightarrow 0$, let $C_{f,x} = C_{f,x,V_w=0}$.
- Then, assuming C_1 remains independent of whether V_w is finite or zero

$$\frac{C_{f,x} V_w}{C_{f,x} V_w=0} = \frac{\ln(1 + B_f)}{B_f}$$

This eqn is applicable to both laminar and turbulent flow. It is derived for $dp/dx = 0$ but can be taken to be valid for mild Pr gr.

So, essentially then N_w would be 1 over $N_w \ln(1 + B_f)$ would equal some constant C_1 . That is what I have written here $\ln(1 + B_f)$ would equal C_1 times N_w and C_1 rho $U_\infty B_f$ over $C_{f,x}$ by 2 because, N_w is ρV_w which can be written as $\rho U_\infty B_f C_{f,x}$ by 2 .

(Refer Slide Time: 07:11)

Momentum Transfer - 1 - L33($\frac{2}{12}$)

- For $\Psi = u$,

$$\frac{d}{dy} \left[N_w u - (\mu + \mu_t) \frac{du}{dy} \right] = 0$$

Integrating once and noting that $u = 0$ at $y = 0$ and $(\mu + \mu_t) (du/dy)|_{y=0} = \tau_w$, the constant of integration $C = -\tau_w$. Hence,

$$\int_0^\infty \frac{du}{N_w u + \tau_w} = \int_0^\delta \frac{dy}{\mu + \mu_t} = C_1 \quad \text{say}$$

$$= \frac{1}{N_w} \ln \left[1 + \frac{N_w U_\infty}{\tau_w} \right]$$

- But,

$$\frac{N_w U_\infty}{\tau_w} = \frac{\rho V_w U_\infty}{\tau_w} = \frac{V_w/U_\infty}{C_{f,x}/2} = B_f \quad (\text{Blowing Parameter})$$

Of course, as B_f tends to 0 , the $C_{f,x}$ must tend to $C_{f,x}$ at V_w equal to 0 and then assuming that this integration, that is, integration 0 to δ $\mu + \mu_t$ would remain the same whether there is mass transfer at the wall or no mass transfer at the wall which

of course would be exactly true if it was a laminar boundary layer. But, even in turbulent boundary layer if we say that μ_t essentially is a function of y and not effected by whether as you will recall from Prandtl's mixing length, there it will not be too seriously affected.

(Refer Slide Time: 07:42)

Momentum Transfer - 1 - L33($\frac{2}{12}$)

• For $\Psi = u$,

$$\frac{d}{dy} \left[N_w u - (\mu + \mu_t) \frac{du}{dy} \right] = 0$$

Integrating once and noting that $u = 0$ at $y = 0$ and $(\mu + \mu_t) (du/dy)|_{y=0} = \tau_w$, the constant of integration $C = -\tau_w$. Hence,

$$\int_0^\infty \frac{du}{N_w u + \tau_w} = \int_0^y \frac{dy}{\mu + \mu_t} = C_1 \quad \text{say}$$

$$= \frac{1}{N_w} \ln \left[1 + \frac{N_w U_\infty}{\tau_w} \right]$$

• But,

$$\frac{N_w U_\infty}{\tau_w} = \frac{\rho V_w U_\infty}{\tau_w} = \frac{V_w / U_\infty}{C_{f,x}/2} = B_f \quad (\text{Blowing Parameter})$$

If we assume C_1 is independent of whether v_w is finite or 0 we can show that it follows from this equation that $C_{f,x} v_w$ divided by $C_{f,x} v_w 0$ would be $\ln \left[1 + \frac{B_f}{B_{f0}} \right]$. This equation is applicable to both laminar and turbulent flows and it is derived for dp/dx equal to 0 but can be taken to be valid even for mild pressure gradients as was done during integral analysis of momentum equations in our previous analysis of fluid flow problems.

Now, for all 4 types of mass transfer I am not going to re-derive as I did in case of Stefan flow. I will simply say that in each case we simply converted the applicable mass transfer and energy transfer equation to a conserved property equation with appropriately defined conserved property ψ .

(Refer Slide Time: 08:40)

General Conv. Mass Transfer - 1 - L33($\frac{4}{12}$)

- For all 4 types of mass transfer, and an appropriately defined conserved property Ψ , $N_w = N_{\Psi,y} = \text{const}$. Hence, for conserved property $(\Psi - \Psi_w)$

$$\frac{d}{dy} \left[N_w (\Psi - \Psi_w) - (\Gamma + \Gamma_t) \frac{d(\Psi - \Psi_w)}{dy} \right] = 0 \text{ or}$$

$$N_w (\Psi - \Psi_w) - (\Gamma + \Gamma_t) \frac{d\Psi}{dy} = C_1 \text{ (say)}$$
- Then, writing this eqn in w- and T-states,

$$C_1 = N_w (\Psi_T - \Psi_w) = -\Gamma \frac{d\Psi}{dy} \Big|_w$$
- Recall that T-state is deep inside the neighbouring phase where Ψ is uniform and hence $(d\Psi/dy)_T = 0$. Also, at the w-state, $\Gamma_t = 0$.

March 25, 2011 9:14

So, for all types of mass transfer and an appropriately defined conserved property, N_w will be equal to $N_{\Psi,y}$ equal to constant and hence for conserved property instead of Ψ , I can also take $\Psi - \Psi_w$ as a conserved property then N_w into $\Psi - \Psi_w$ minus $\Gamma + \Gamma_t$ $d(\Psi - \Psi_w)/dy$ is equal to 0 or N_w into $\Psi - \Psi_w$ minus $\Gamma + \Gamma_t$ $d\Psi/dy$ equal to C_1 - some constants C_1 . Now, remember $d\Psi_w/dy$ is of course always 0, so that is that does not appear here but $d\Psi/dy$ would certainly survive.

Then if I write this equation in the w state then I would get C_1 equal to $\Gamma d\Psi/dy$ at y equal to 0 and if I write it in the T-state I will get $N_w \Psi_T - \Psi_w$ and in the T-state there are no variations of Ψ and therefore this entire term would be 0. Again, C_1 and therefore equating the 2 equations, because they are both equal to C_1 , I would get C_1 equal to $N_w \Psi_T - \Psi_w$ equal to minus $\Gamma d\Psi/dy$ at w and at w-state Γ_t is equal to 0; so that is what I have stated here.

(Refer Slide Time: 10:33)

General Conv. Mass Transfer - 2 - L33($\frac{5}{12}$)

- Hence, replacing $C_1 = N_w (\Psi_T - \Psi_w)$, we have

$$N_w (\Psi - \Psi_T) - (\Gamma + \Gamma_t) \frac{d\Psi}{dy} = 0$$
- Integrating this Eqn from w-state ($y = 0$) to ∞ -state ($y = \delta$)

$$\frac{1}{N_w} \int_0^\infty \frac{d\Psi}{(\Psi - \Psi_T)} = \int_0^\delta \frac{dy}{\Gamma + \Gamma_t} = C_2 \text{ (say)}$$
- Or, integration of LHS gives

$$N_w = \frac{1}{C_2} \ln(1 + B_\Psi) \rightarrow B_\Psi = \frac{\Psi_\infty - \Psi_w}{\Psi_w - \Psi_T} \text{ (and)}$$

$$N_w = \frac{C_1}{\Psi_T - \Psi_w} = \frac{-\Gamma (d\Psi/dy)_w}{\Psi_T - \Psi_w}$$

We shall make use of this equation and substitute for C 1 here. C 1 equal to N w psi t minus psi w; I will substitute that here on the next slide and you will see that therefore, I would get N w psi minus psi t minus gamma plus gamma t d psi by dy equal to 0. If I integrate this equation from w-state y equal to 0 to infinity state y equal to delta then I will get 1 over N w equal to 0 to infinity d psi by dy d psi by psi minus psi t equal to 0 to delta dy gamma plus gamma t, where gamma in case of energy gamma is k by C p in case of species transfer it is rho m times diffusivity.

(Refer Slide Time: 11:41)

General Conv. Mass Transfer - 1 - L33($\frac{4}{12}$)

- For all 4 types of mass transfer, and an appropriately defined conserved property Ψ , $N_w = N_{\Psi,y} = \text{const}$. Hence, for conserved property ($\Psi - \Psi_w$)

$$\frac{d}{dy} \left[N_w (\Psi - \Psi_w) - (\Gamma + \Gamma_t) \frac{d(\Psi - \Psi_w)}{dy} \right] = 0 \text{ or}$$

$$N_w (\Psi - \Psi_w) - (\Gamma + \Gamma_t) \frac{d\Psi}{dy} = C_1 \text{ (say)}$$
- Then, writing this eqn in w- and T-states,

$$C_1 = N_w (\Psi_T - \Psi_w) = -\Gamma \frac{d\Psi}{dy} \Big|_w$$
- Recall that T-state is deep inside the neighbouring phase where Ψ is uniform and hence $(d\Psi/dy)_T = 0$. Also, at the w-state, $\Gamma_t = 0$.

(Refer Slide Time: 11:46)

General Conv. Mass Transfer - 2 - L33($\frac{5}{12}$)

- Hence, replacing $C_1 = N_w (\Psi_T - \Psi_w)$, we have

$$N_w (\Psi - \Psi_T) - (\Gamma + \Gamma_r) \frac{d\Psi}{dy} = 0$$
- Integrating this Eqn from w-state ($y = 0$) to ∞ -state ($y = \delta$)

$$\frac{1}{N_w} \int_0^{\infty} \frac{d\Psi}{(\Psi - \Psi_T)} = \int_0^{\delta} \frac{dy}{\Gamma + \Gamma_r} = C_2 \text{ (say)}$$
- Or, integration of LHS gives

$$N_w = \frac{1}{C_2} \ln(1 + B_\Psi) \rightarrow B_\Psi = \frac{\Psi_\infty - \Psi_w}{\Psi_w - \Psi_T} \text{ (and)}$$

$$N_w = \frac{C_1}{\Psi_T - \Psi_w} = \frac{-\Gamma (d\Psi/dy)_w}{\Psi_T - \Psi_w}$$

So, let us say that integral like in the previous case we will say is equal to C 2. Let us say then the integration of the left hand side would give me N w equal to 1 over C 2 ln plus B psi because, same as previous case B psi is equal to psi infinity minus psi w divided by psi w minus psi T. N w will be from the previous slide N w would be C 1 divided by psi T minus psi w and that would equal minus gamma d psi by dy at w psi T minus psi w. So, we have got 1 equation which is of this form and the other equation which is of this form the first containing C 2 and the second containing C 1.

(Refer Slide Time: 12:05)

General Conv. Mass Transfer - 3 - L33($\frac{6}{12}$)

- Now, consistent with the theory of heat transfer, we may write

$$-\Gamma \frac{d\Psi}{dy} \Big|_w = g \times (\Psi_w - \Psi_\infty)$$
 where g is the mass transfer coefficient ($\text{kg/m}^2\text{-s}$)
- Then,

$$N_w = g \times \left(\frac{\Psi_\infty - \Psi_w}{\Psi_w - \Psi_T} \right) = g \times B_\Psi \text{ and}$$

$$g = \frac{1}{C_2} \frac{\ln(1 + B_\Psi)}{B_\Psi}$$
- Let $g \rightarrow g^*$ as $B_\Psi \rightarrow 0$. Further, let C_2 remain same for with and without mass transfer. Then

$$\frac{g}{g^*} = \frac{\ln(1 + B_\Psi)}{B_\Psi}$$

Now, consistent with the theory of heat transfer, we may write minus gamma d psi by dy at w is equal to g times psi w minus psi infinity, where g is now the mass transfer coefficient.

(Refer Slide Time: 12:29)

General Conv. Mass Transfer - 2 - L33($\frac{5}{12}$)

- Hence, replacing $C_1 = N_w (\Psi_T - \Psi_w)$, we have

$$N_w (\Psi - \Psi_T) - (\Gamma + \Gamma_T) \frac{d\Psi}{dy} = 0$$
- Integrating this Eqn from w-state ($y = 0$) to ∞ -state ($y = \delta$)

$$\frac{1}{N_w} \int_0^{\infty} \frac{d\Psi}{(\Psi - \Psi_T)} = \int_0^{\delta} \frac{dy}{\Gamma + \Gamma_T} = C_2 \text{ (say)}$$
- Or, integration of LHS gives

$$N_w = \frac{1}{C_2} \ln(1 + B_\Psi) \rightarrow B_\Psi = \frac{\Psi_\infty - \Psi_w}{\Psi_w - \Psi_T} \text{ (and)}$$

$$N_w = \frac{C_1}{\Psi_T - \Psi_w} = \frac{-\Gamma (d\Psi/dy)_w}{\Psi_T - \Psi_w}$$

March 25, 2011 17/14

(Refer Slide Time: 12:38)

General Conv. Mass Transfer - 3 - L33($\frac{6}{12}$)

- Now, consistent with the theory of heat transfer, we may write

$$-\Gamma \frac{d\Psi}{dy} \Big|_w = g \times (\Psi_w - \Psi_\infty)$$
 where g is the mass transfer coefficient ($\text{kg/m}^2\text{-s}$)
- Then,

$$N_w = g \times \left(\frac{\Psi_\infty - \Psi_w}{\Psi_w - \Psi_T} \right) = g \times B_\Psi \text{ and}$$

$$g = \frac{1}{C_2} \frac{\ln(1 + B_\Psi)}{B_\Psi}$$
- Let $g \rightarrow g^-$ as $B_\Psi \rightarrow 0$. Further, let C_2 remain same for with and without mass transfer. Then

$$\frac{g}{g^-} = \frac{\ln(1 + B_\Psi)}{B_\Psi}$$

March 25, 2011 18/14

If I replace this quantity by this quantity in the previous expression here then, I can get C 1 from there in terms of g. Therefore, the final form would look like N w equal to g time psi infinity minus psi w divided by psi w minus psi T, or simply g times B psi and g itself would be 1 over C 2 times ln 1 plus B psi divided by B psi.

If I assume that as $B\psi$ tends to 0 g tends to g^* , the mass transfer coefficient let us say it tends to g^* corresponding to $B\psi$ tending to 0. Further, and if I say that C_2 remains constant with or without mass transfer as we said earlier, this statement is of course perfectly true for laminar boundary layer. But, even if I say it is true for turbulent boundary layer where 1 over g would be function of y then, it follows that g over g^* would be simply $\ln(1 + B\psi)$ by $B\psi$.

(Refer Slide Time: 13:51)

Comments - 1 - L33($\frac{7}{12}$)

- Thus, the fictitious g^* flux is given by

$$N_w = g^* \ln(1 + B\psi) \quad \text{where} \quad \frac{1}{g^*} = C_2 = \int_0^\delta \frac{dy}{\Gamma + \Gamma_t}$$

- Thus, g^* may be viewed as the sum of layer-by-layer resistances to mass transfer in the considered phase over the width δ
- This interpretation of g^* enables its evaluation from known $\Gamma(y) = \Gamma(\psi)$ in a laminar BL and from known $\Gamma_t(y)$ from a turbulence model (mixing length, for example) in a turbulent BL. Thus, the Couette flow model permits study of property variations.
- In fact, if $\Gamma = \text{const}$ and $\Gamma_t = 0$ then $g^* = \Gamma/\delta$ which is same as the Stefan flow model with $g^* = \Gamma/L$.

March 25, 2011 9/18

This is a very important result thus the fictitious g^* flux is now given by $N_w = g^* \ln(1 + B\psi)$, where 1 over g^* is equal to C_2 which is equal to $\int_0^\delta \frac{dy}{\Gamma + \Gamma_t}$ over $\Gamma + \Gamma_t$.

So we can now view g^* itself as the sum of layer by layer from 0 to δ resistances to mass transfer in the considered phase over the width δ because, remember this is the diffusion coefficient. So, one over diffusion coefficient would simply be resistances resistance and we are simply saying that 1 over g^* which itself is a kind of a resistance because g^* is conductance then 1 over g^* would be simply layer by layer addition of resistances to mass transfer in the considered phase.

This interpretation of g^* enables its evaluation from $\Gamma(y) = \Gamma(\psi)$ in a laminar boundary layer and from the known $\Gamma_t(y)$ from a turbulence model like a mixing length. Or for example, in a turbulent boundary layer thus the Couette flow model permits study of the property variations. Remember, a Γ itself could be a

function of psi of temperature or the mass fraction itself gamma t on the other hand would be function of the turbulence characteristics of the boundary layer. In fact, if gamma is equal to constant and gamma t is equal to 0 which is the case of a laminar diffusion problem, then g star would be simply gamma by delta which is same as the Stefan flow model in which g star was shown to be equal to gamma by L.

We have recovered most of the features of the Stefan flow model for gamma equal to constant and gamma t equal to 0 and g star would then be gamma by L ln 1 plus B psi which is what we had shown in the Stefan flow model.

(Refer Slide Time: 16:03)

Comments - 2 - L33($\frac{8}{12}$)

- Further, if we consider case of pure heat transfer in the presence of suction or blowing, with $\psi = h_m - c_p T$

$$-k \frac{dT}{dy} \Big|_w = g c_p (T_w - T_\infty) = h_{cof, v_w} (T_w - T_\infty)$$

where h_{cof, v_w} is heat transfer coefficient.

- Then, $h_{cof, v_w} = g/c_p$ and $h_{cof, v_w=0} = g^*/c_p$
- Hence,

$$\frac{g}{g^*} = \frac{h_{cof, v_w}}{h_{cof, v_w=0}} = \frac{St_{x, v_w}}{St_{x, v_w=0}} = \frac{\ln(1 + B_h)}{B_h} \quad \rightarrow \quad B_h = \frac{T_\infty - T_w}{T_w - T_T}$$

- This relationship was found to be applicable in a real boundary layer in lecture 30. Thus, the Couette flow model captures most features of a real boundary layer.

Mar 25, 2011 12:14

Now, if we consider the case of pure heat transfer in the presence of suction and blowing something we have solved by similarity method then, with psi is equal to h m equal to C p T because it is an inert situation, just considered phase as air flowing over it and suction and blown fluid is same as the fluid in the considered phase its temperature may be same or different, that does not matter. **but** Therefore, we would get minus k d T dy equal to 0 which is the heat flux and that would equal g times C p into T w minus T infinity according to our model and that would equal heat transfer coefficient for suction and blowing into T w minus T infinity.

So, that is what the heat transfer coefficient is and therefore we deduce that the heat transfer coefficient for finite v w is nothing but g by C p and likewise h cof v w equal to 0; that is in the absence of mass transfer would be equal to g star by C p because g star is

a value of g when v_w is equal to 0. Therefore, we deduce that g over g^* would also be equal to h of v_w divided by h of $v_w = 0$ equal to $\text{Stanton } x$ at v_w for v_w divided by $\text{Stanton } x$ for v_w equal to 0. That would equal $\ln B_h$ by B_h where B_h now is T_∞ minus T_w over T_w minus T_w because, specific heats in all states are taken to be constant at the moment.

Now, this relation was found to be applicable in real boundary layer flow in lecture 30, we will recall and therefore the Couette flow model captures also the features of a real boundary layer flow.

So the Couette flow model on the one hand when γ_t is 0 captures this Stefan flow model feature and it also captures the boundary layer flow features at least when the species are the same; it captures both the features.

(Refer Slide Time: 18:23)

Evaporation/Burning times - 1 - L33($\frac{9}{12}$)

- The previous expressions can be used **instantaneously**, to estimate **evaporation/burning times**. Thus

$$\rho_l \frac{dV}{dt} = -\dot{m}_w = -A_w N_w = -A_w g^* \ln(1 + B_\psi)$$

Integrating from $t = 0$ ($V = V_i$) to $t = t_{\text{evap, burn}}$ ($V = 0$) gives

$$t_{\text{evap, burn}} = -\frac{\rho_l}{\ln(1 + B_\psi)} \int_{V_i}^0 \frac{dV}{A_w g^*}$$

- For a **liquid drop and diffusion mass transfer**, $A_w = 4\pi r_w^2$, $V = (4/3)\pi r_w^3$, and $g^* = \Gamma_{mh}/r_w$. Hence,

$$t_{\text{evap, burn}} = -\frac{\rho_l}{\ln(1 + B_\psi)} \int_{r_{w,i}}^0 \frac{r_w}{\Gamma_{mh}} dr_w = \frac{\rho_l D_{w,j}^2}{8 \Gamma_{mh} \ln(1 + B_\psi)}$$

March 28, 2011 11 / 18

Now, we turn to the application of these two evaporation and burning in which we shall invoke the previous expression **for** can be used instantaneously to estimate the evaporation or burning time. Thus, let us say if I have $\rho_l dV$ by dt is equal to minus \dot{m}_w which is the rate of change of mass is equal to minus \dot{m}_w kg per second and that would equal $A_w N_w$ and that would equal minus $A_w g^* \ln(1 + B_\psi)$ where A_w is the area of the surface through which the mass transfer is taking place.

Then, integrating this from time t equal to 0 to complete evaporation when the volume disappears gives us the relationship t evaporation or burned is equal to $\frac{\rho_l}{\rho_g} \ln \left(\frac{1+B\psi}{1} \right)$ plus $B\psi$ equal to $\frac{v_{initial}}{0} \frac{dV}{A w g^*}$. Now, let us say if we are considering a liquid droplet and diffusion mass transfer that is γ_t is equal to 0 then $A w$ will be equal to $4 \pi r w$ square V will be $\frac{4}{3} \pi r^3 w$ square and g^* will be $\gamma_m h$ by $r w$. As you will recall then, hence you will see that evaporation or burning time would be $\frac{\rho_l}{\rho_g} \ln \left(\frac{1+B\psi}{1} \right)$ divided by $\frac{1}{r w} \frac{dV}{dt}$ to $\frac{0}{r w} \frac{dV}{dt}$ by $\gamma_m h$ $dr w$ and that will yield the so called D squared law $\rho_l D w^2 \ln \left(\frac{1+B\psi}{1} \right)$ times $\gamma_m h$.

This expression is used extensively in designing dryers and so on because, all it says is that if you reduce, the smaller the diameter of the droplet, faster will be the drying achieved; because, if you reduce the diameter by a factor of 2 the evaporation time will reduce by factor of 4 in stagnant surrounding. This will be considered as a guidance for atomization of fuels atomization of let us say milk which is to be dried into a powder and or in a cooling tower where you send hot cooling water for cooling purposes, then in a shower, then you want to reduce the diameter as small as possible so that you get very quick drying and a smaller dryer or a cooling tower.

(Refer Slide Time: 21:08)

Evaporation/Burning times - 2 - L33^(10/12)

- For a liquid drop and Convective mass transfer, g^* can be determined by a short-cut method. Thus,

$$\frac{\dot{m}_{w,conv}}{\dot{m}_{w,diff}} = \frac{g^* 4 \pi r_w^2 \ln [1+B]}{\rho_m D 4 \pi r_w \ln [1+B]} = \frac{1}{2} \left[\frac{g^* D_w}{\rho_m D} \right] = \frac{Sh}{2}$$
 where $Sh \equiv$ Sherwood Number.
- Using analogy between HT & MT ($Le = 1$)

$$Sh = \frac{g^* D_w}{\Gamma_{mh}} = 2 + 0.6 Re^{0.5} Sc^{1/3} \quad \rightarrow \quad Re = \frac{|u_g - u_p| D_w}{\nu_m}$$
 where $|u_g - u_p| \equiv$ relative vel between drop and gas.
- Then,

$$t_{evap,burn} = \frac{2 \rho_l}{\ln(1+B\psi)} \int_{r_{in}}^0 \frac{r_w dr_w}{\Gamma_{mh} (2 + 0.6 Re_{D_w}^{0.5} Sc^{1/3})}$$

This evaluation requires numerical integration

Now, let us say the liquid droplet was in a convective environment as in inside a diesel engine whereas, you know in a diesel engine the liquid droplets are injected in a atomized state and they come out like a cloud. When the piston is at d t top dead center,

the temperature is already very high in the surroundings and the droplets evaporate and then burn inside the cylinder.

We can assess **such** we can evaluate the evaporation or drying times for evaporation or burning times in such situations; but, the environment there is convective because the pistons head is modeled in such a way that there is a swell inside the cylinder. So, the air movement and the particle and the droplet movement there is a relative velocity between them. So, essentially you get now convective evaporation or convective drying. Same thing happens when you have a cooling tower where the droplet is falling down through, let us say, stagnant air; but, that sets up a resultant velocity between the droplet and the surrounding air which is stagnant.

(Refer Slide Time: 22:39)

On the other hand, in thermal power stations you will recall that we have cooling towers like that and the air ingresses like this. **and on** Here you have showers of water where the cooling water from the condenser falls down and there is an air. So, you have a counter current of air and water and therefore the liquid droplets evaporate under counter flow. So, the relative velocity is additive of the air flow and the water flow droplet flow which is coming down step in the process that the water gets cooled and they send back to condenser. Of course, some amount of water is lost because the air moving upwards picks up some moisture which has to be topped up; of course, from time to time so that the condenser is not starved of cooled water.

(Refer Slide Time: 23:35)

Evaporation/Burning times - 2 - L33(¹⁰/₁₂)

● For a liquid drop and Convective mass transfer, g^* can be determined by a short-cut method. Thus,

$$\frac{\dot{m}_{w, conv}}{\dot{m}_{w, diff}} = \frac{g^* 4 \pi r_w^2 \ln [1 + B]}{\rho_m D 4 \pi r_w \ln [1 + B]} = \frac{1}{2} \left[\frac{g^* D_w}{\rho_m D} \right] = \frac{Sh}{2}$$

where $Sh \equiv$ Sherwood Number.

● Using analogy between HT & MT ($Le = 1$)

$$Sh = \frac{g^* D_w}{\Gamma_{mh}} = 2 + 0.6 Re^{0.5} Sc^{1/3} \rightarrow Re = \frac{|u_g - u_p| D_w}{\nu_{fl}}$$

where $|u_g - u_p| \equiv$ relative vel between drop and gas.

● Then,

$$t_{evap, burn} = - \frac{2 \rho_l}{\ln(1 + B_\psi)} \int_{r_w}^0 \frac{r_w dr_w}{\Gamma_{mh} (2 + 0.6 Re_{D_w}^{0.5} Sc^{1/3})}$$

This evaluation requires numerical integration

March 25, 2011 07:34

In such situation, we can use a short cut method and thus we can say that $\dot{m}_{w, conv}$ that is mass transfer rate under convection divided by mass transfer rate under diffusion would be mass transfer rate under convection. According to the Couette flow model is g^* star times A_w which is $4 \pi r_w^2 \ln [1 + B]$ and mass transfer rate. According to diffusion model which is a Stefan flow model is, $\rho_m D 4 \pi r_w \ln [1 + B]$. Therefore, canceling the terms you will get $\frac{1}{2} g^* D_w$ which is the diameter of the droplet divided by ρ_m diffusivity and this quantity like Nusselt number is called the Sherwood number in mass transfer. The analog analogous to Nusselt number, we have a Sherwood number which is essentially g^* the mass transfer coefficient into the diameter divided by $\rho_m D$ which is equivalent of the conductivity of the fluid.

(Refer Slide Time: 25:32)

Evaporation/Burning times - 1 - L33($\frac{9}{12}$)

- The previous expressions can be used **instantaneously**, to estimate **evaporation/burning times**. Thus

$$\rho_l \frac{dV}{dt} = -\dot{m}_w = -A_w N_w = -A_w g^* \ln(1 + B_\psi)$$

Integrating from $t = 0$ ($V = V_i$) to $t = t_{\text{evap.burn}}$ ($V = 0$) gives

$$t_{\text{evap.burn}} = -\frac{\rho_l}{\ln(1 + B_\psi)} \int_{V_i}^0 \frac{dV}{A_w g^*}$$

- For a **liquid drop** and **diffusion mass transfer**, $A_w = 4\pi r_w^2$, $V = (4/3)\pi r_w^3$, and $g^* = \Gamma_{mh}/r_w$. Hence,

$$t_{\text{evap.burn}} = -\frac{\rho_l}{\ln(1 + B_\psi)} \int_{r_{w,i}}^0 \frac{r_w}{\Gamma_{mh}} dr_w = \frac{\rho_l D_{w,i}^2}{8 \Gamma_{mh} \ln(1 + B_\psi)}$$

(Refer Slide Time: 25:35)

Evaporation/Burning times - 2 - L33($\frac{10}{12}$)

- For a **liquid drop** and **Convective mass transfer**, g^* can be determined by a **short-cut method**. Thus,

$$\frac{\dot{m}_{w,conv}}{\dot{m}_{w,diff}} = \frac{g^* 4\pi r_w^2 \ln(1 + B)}{\rho_m D 4\pi r_w \ln(1 + B)} = \frac{1}{2} \left[\frac{g^* D_w}{\rho_m D} \right] = \frac{Sh}{2}$$

where $Sh \equiv$ Sherwood Number.

- Using analogy between HT & MT ($Le = 1$)

$$Sh = \frac{g^* D_w}{\Gamma_{mh}} = 2 + 0.6 Re^{0.5} Sc^{1/3} \rightarrow Re = \frac{|u_g - u_p| D_w}{\nu_m}$$

where $|u_g - u_p| \equiv$ relative vel between drop and gas.

- Then,

$$t_{\text{evap.burn}} = -\frac{2 \rho_l}{\ln(1 + B_\psi)} \int_{r_{w,i}}^0 \frac{r_w dr_w}{\Gamma_{mh} (2 + 0.6 Re_{D_w}^{0.5} Sc^{1/3})}$$

This evaluation requires numerical integration

Now, if I use analogy between heat and mass transfer for Lewis number 1 then, you know that the for a flow over a sphere you know that the Nusselt number is 2 plus 0.6, Reynolds raised to 0.5, Prandtl raised to third, but I can now say Sherwood number would be 2 times 0.6 Re raised to 0.5 Schmidt number raised to one-third where Re **is the** is based on the relative velocity between the gas and the droplet - the diameter of the droplet and the kinematic viscosity. Or this expression for example, would now get changed to 2 times rho l ln 1 plus B psi r w i to 0 r w dr w divided by gamma h 2 plus 0.6 Re D w 0.5 Schmidt number raised to 1 by 3.

Now, since this also contains the radius r_w wired because D_w is 2 times r_w this expression integration requires numerical integration because close form solutions are not found.

(Refer Slide Time: 26:13)

Problem - L33(11/12)

Prob: A water droplet ($D_{w,i} = 1$ mm) at 25°C evaporates in air (RH - 25 %, $T = 25^\circ\text{C}$) with $u_{rel} = 5$ m/s. Estimate evaporation time. Take $Sc = 0.6$

Soln: This is inert MT without HT. The mass fractions are:
 $w_{v,w} = 0.0078$, $w_{v,a} = 0.02$.
 Therefore $B_m = 0.0124$.
 $\rho_m = 1,177$ kg/m³,
 $\rho_a = 1000$ kg/m³,
 $D_m = 2.376 \times 10^{-5}$ and
 $\nu_m = D_m \times Sc = 1.42 \times 10^{-5}$.

Num. Int. - $\Delta t = 0.01$ sec.
Ans. Evaporation time at $r_w = 0$ is 2.045 sec. If $u_{rel} = 0$, then Evaporation time = 4.66 sec.

Let us take for example: if I took a problem, let us say a water droplet D_w is 1 millimeter diameter at 25 degree centigrade evaporates in air whose relative humidity is let us say 25 percent then and temperature is 25 degree centigrade, so that this is a case of mass transfer without heat transfer and no chemical reaction. Let us assume that the relative velocity between the 2 is 5 meters per second; so estimate the evaporation time and take Schmidt number equal to 0.6 which is quite typical of gaseous mixture.

(Refer Slide Time: 27:20)

General Conv. Mass Transfer - 2 - L33($\frac{5}{12}$)

● Hence, replacing $C_1 = N_w (\Psi_T - \Psi_w)$, we have

$$N_w (\Psi - \Psi_T) - (\Gamma + \Gamma_1) \frac{d\Psi}{dy} = 0$$

● Integrating this Eqn from w-state ($y = 0$) to ∞ -state ($y = \delta$)

$$\frac{1}{N_w} \int_0^\infty \frac{d\Psi}{(\Psi - \Psi_T)} = \int_0^\delta \frac{dy}{\Gamma + \Gamma_1} = C_2 \text{ (say)}$$

● Or, integration of LHS gives

$$N_w = \frac{1}{C_2} \ln(1 + B_m) \rightarrow B_m = \frac{\Psi_\infty - \Psi_w}{\Psi_w - \Psi_T} \text{ (and)}$$

$$N_w = \frac{C_1}{\Psi_T - \Psi_w} = \frac{-\Gamma (d\Psi/dy)_w}{\Psi_T - \Psi_w}$$

So, this is a mass inert mass transfer problem without heat transfer the mass fractions are in the infinity state corresponding to 25 percent RH and T equal to 25 will give you ω_v infinity equal to 0.0078 ω_v w corresponding to 100 percent relative humidity at the droplet surface. 25 degree centigrade will be 0.02 B m, would be ω_v vapor and the infinity state minus ω_v vapor in the w state and ω_v vapor in the w state minus in the T state which is the transfer state and that would be equal to 1.

(Refer Slide Time: 27:39)

Problem - L33($\frac{11}{12}$)

Prob: A water droplet ($D_{w,i} = 1$ mm) at 25°C evaporates in air (RH - 25 %, T = 25°C) with $u_{rel} = 5$ m/s. Estimate evaporation time. Take Sc = 0.6

Soln: This is inert MT without HT. The mass fractions are:
 $\omega_{v,\infty} = 0.0078$, $\omega_{v,w} = 0.02$.
 Therefore $B_m = 0.0124$.
 $\rho_m = 1.177 \text{ kg/m}^3$,
 $\rho_l = 1000 \text{ kg/m}^3$,
 $D_m = 2.376 \times 10^{-5}$ and
 $\nu_m \approx D_m \times Sc = 1.42 \times 10^{-5}$.

Num. Int. - $\Delta t = 0.01$ sec.
Ans: Evaporation time at $r_w = 0$ is 2.045 sec. If $u_{rel} = 0$, then Evaporation time = 4.66 sec.

So, using this definition for omega v as we did in problems on diffusion mass transfer the B m would turn out to be 0.0124 at the mean conditions between the infinity and w states mixture density can be evaluated as 1.177 kilograms per meter cube. Liquid density would be 1000 kg per meter cube; whereas, a water diffusivity from the **lectures** we say that the diffusivity of water vapor through air is 2.376 into 10 raise to minus 5 and nu m will be diffusivity into Schmidt number which will be equal to 1.42 into 10 raise to minus 6.

(Refer Slide Time: 28:31)

Evaporation/Burning times - 2 - L33(¹⁰/₁₂)

- For a liquid drop and Convective mass transfer, g^* can be determined by a short-cut method. Thus,

$$\frac{\dot{m}_{w,conv}}{\dot{m}_{w,diff}} = \frac{g^* 4\pi r_w^2 \ln[1+B]}{\rho_m D 4\pi r_w \ln[1+B]} = \frac{1}{2} \left[\frac{g^* D_w}{\rho_m D} \right] = \frac{Sh}{2}$$
 where $Sh \equiv$ Sherwood Number.
- Using analogy between HT & MT ($Le = 1$)

$$Sh = \frac{g^* D_w}{\Gamma_{mh}} = 2 + 0.6 Re^{0.5} Sc^{1/3} \rightarrow Re = \frac{|u_g - u_p| D_w}{\nu_m}$$
 where $|u_g - u_p| \equiv$ relative vel between drop and gas.
- Then,

$$t_{evap,burn} = - \frac{2 \rho_l}{\ln(1+B_w)} \int_{r_w}^0 \frac{r_w dr_w}{\Gamma_{mh} (2 + 0.6 Re_{D_w}^{0.5} Sc^{1/3})}$$

This evaluation requires numerical integration

(Refer Slide Time: 28:34)

Problem - L33(¹¹/₁₂)

Prob: A water droplet ($D_{w,l} = 1$ mm) at 25°C evaporates in air (RH = 25%, T = 25°C) with $u_{rel} = 5$ m/s. Estimate evaporation time. Take $Sc = 0.6$

Soln: This is inert MT without HT. The mass fractions are:
 $w_{v,\infty} = 0.0078$, $w_{v,w} = 0.02$.
 Therefore $B_m = 0.0124$.
 $\rho_m = 1.177$ kg/m³,
 $\rho_l = 1000$ kg/m³,
 $D_m = 2.376 \times 10^{-5}$ and
 $\nu_m = D_m \times Sc = 1.42 \times 10^{-6}$.

Num. Int. - $\Delta t = 0.01$ sec.
Ans: Evaporation time at $r_w = 0$ is 2.045 sec. If $u_{rel} = 0$, then Evaporation time = 4.66 sec.

(Refer Slide Time: 28:40)

Evaporation/Burning times - 2 - L33(10/12)

● For a liquid drop and Convective mass transfer, g^* can be determined by a short-cut method. Thus,

$$\frac{\dot{m}_{w,conv}}{\dot{m}_{w,diff}} = \frac{g^* 4\pi r_w^2 \ln[1+B]}{\rho_m D 4\pi r_w \ln[1+B]} = \frac{1}{2} \left[\frac{g^* D_w}{\rho_m D} \right] = \frac{Sh}{2}$$

where $Sh \equiv$ Sherwood Number.

● Using analogy between HT & MT ($Le = 1$)

$$Sh = \frac{g^* D_w}{\Gamma_{mh}} = 2 + 0.6 Re^{0.5} Sc^{1/3} \rightarrow Re = \frac{|u_g - u_p| D_w}{\nu_m}$$

where $|u_g - u_p| \equiv$ relative vel between drop and gas.

● Then,

$$t_{evap,burn} = - \frac{2 \rho_l}{\ln(1+B_w)} \int_{r_w}^0 \frac{r_w dr_w}{\Gamma_{mh} (2 + 0.6 Re_{D_w}^{0.5} Sc^{1/3})}$$

This evaluation requires numerical integration

(Refer Slide Time: 28:46)

Problem - L33(11/12)

Prob: A water droplet ($D_{w,l} = 1$ mm) at 25°C evaporates in air (RH = 25%, $T = 25^\circ\text{C}$) with $u_{rel} = 5$ m/s. Estimate evaporation time. Take $Sc = 0.6$

Soln: This is inert MT without HT. The mass fractions are:
 $w_{v,\infty} = 0.0078$, $w_{v,w} = 0.02$.
 Therefore $B_m = 0.0124$.
 $\rho_m = 1.177 \text{ kg/m}^3$,
 $\rho_l = 1000 \text{ kg/m}^3$,
 $D_m = 2.376 \times 10^{-5}$ and
 $\nu_m = D_m \times Sc = 1.42 \times 10^{-5}$.

Num. Int. - $\Delta t = 0.01$ sec.
Ans: Evaporation time at $r_w = 0$ is 2.045 sec. If $u_{rel} = 0$, then Evaporation time = 4.66 sec.

So, knowing nu_m we can evaluate and u relative we can evaluate the Reynolds number that is required here. In the Reynolds number expression and D_m which is required here to calculate γ_h because this is $\rho \times D_m$. So, we can carry out the numerical integration with time step 0.01 second. Then evaporation time at r_w equal to 0 would be 2.05 second and the radius would vary in this fashion 0.5 mm to start with and then it drops down very gradually to 0 value here at above 2.045 seconds.

(Refer Slide Time: 29:28)

Evaporation/Burning times - 2 - L33(10)

● For a liquid drop and Convective mass transfer, g^* can be determined by a short-cut method. Thus,

$$\frac{\dot{m}_{w,conv}}{\dot{m}_{w,diff}} = \frac{g^* 4 \pi r_w^2 \ln [1 + B]}{\rho_m D 4 \pi r_w \ln [1 + B]} = \frac{1}{2} \left[\frac{g^* D_w}{\rho_m D} \right] = \frac{Sh}{2}$$

where $Sh \equiv$ Sherwood Number.

● Using analogy between HT & MT ($Le = 1$)

$$Sh = \frac{g^* D_w}{\Gamma_{mh}} = 2 + 0.6 Re^{0.5} Sc^{1/3} \rightarrow Re = \frac{|u_g - u_p| D_w}{\nu_m}$$

where $|u_g - u_p| \equiv$ relative vel between drop and gas.

● Then,

$$t_{evap,burn} = - \frac{2 \rho_l}{\ln(1 + B_w)} \int_{r_w}^0 \frac{r_w dr_w}{\Gamma_{mh} (2 + 0.6 Re_{D_w}^{0.5} Sc^{1/3})}$$

This evaluation requires numerical integration

(Refer Slide Time: 29:34)

Problem - L33(11)

Prob: A water droplet ($D_{w,l} = 1$ mm) at 25°C evaporates in air (RH = 25%, $T = 25^\circ\text{C}$) with $u_{rel} = 5$ m/s. Estimate evaporation time. Take $Sc = 0.6$

Soln: This is inert MT without HT. The mass fractions are:
 $w_{v,\infty} = 0.0078$, $w_{v,w} = 0.02$.
 Therefore $B_m = 0.0124$.
 $\rho_m = 1.177 \text{ kg/m}^3$,
 $\rho_l = 1000 \text{ kg/m}^3$,
 $D_m = 2.376 \times 10^{-5}$ and
 $\nu_m = D_m \times Sc = 1.42 \times 10^{-5}$.

Num. Int. - $\Delta t = 0.01$ sec.
Ans: Evaporation time at $r_w = 0$ is 2.045 sec. If $u_{rel} = 0$, then Evaporation time = 4.66 sec.

We can solve the same problem in stagnant surroundings by simply setting u relative equal to 0; which means that the Reynolds number here is 0 and therefore this will be 2 times γh . Then you will see that the evaporation time becomes 4.66 seconds. So, clearly having a relative velocity between the gas and the droplet has reduced the evaporation time and this is the principle that is used in cooling towers and in diesel engines for the purposes of reducing the size. In case of cooling towers and in diesel engines, this is of great value because it enhances the rate of burning of the fuel and

which incidentally also reduces the cut off ratio of a diesel engine which in turn improves the efficiency of the engine.

(Refer Slide Time: 30:28)

Summary - L33(12/12)

- In the Couette flow model with $A = \text{const}$, $u = \text{const} \times y$ and $d\Psi / dx = 0$, we have shown that

$$N_w = g^* \ln(1 + B_\psi) \quad \text{where} \quad \frac{g}{g^*} = \frac{\ln(1 + B_\psi)}{B_\psi}$$
- The fictitious g^* flux is interpreted as the sum of layer-by-layer resistances to mass transfer in the considered phase over boundary layer width
- In pure momentum and heat transfer in the presence of suction/blowing

$$\frac{C_{f,x,V_w}}{C_{f,x,V_w=0}} = \frac{\ln(1 + B_f)}{B_f} \quad \frac{St_{x,V_w}}{St_{x,V_w=0}} = \frac{\ln(1 + B_h)}{B_h}$$
- In the following lectures, we shall develop similar results using algebraic Reynolds flow model.

So, finally in summary then we can say that a Couette flow model with area equal to constant and u equal to constant times y and $d\psi$ by dx equal to 0 gives us the formula N_w equal to $g^* \ln(1 + B_\psi)$, where g/g^* is equal to $\ln(1 + B_\psi) / B_\psi$.

We interpreted the g^* flux as the sum of the layer by layer resistances to mass transfer in the considered phase over boundary layer width in pure momentum and heat transfer in the presence of suction and blowing. That is without gradients of species of any kind because the same species being sucked or blown. We have shown that $C_{f,x}$ in the presence of suction and blowing divided by $C_{f,x}$ in the absence of it is simply $\ln(1 + B_f) / B_f$ and the heat transfer likewise would be $\ln(1 + B_h) / B_h$.

So, Couette flow model recovers essentially the results expected from a boundary layer flow model it also recovers the results expected from the Stefan flow model and in turn gives us an opportunity to evaluate the effect the property variations which we shall take up in subsequent lectures.

So, in the next lecture we will develop very similar results to what we have shown in Couette flow model via the algebraic Reynolds flow model and you will see what form N and B relation has as per the Reynolds algebraic Reynolds flow model.
