

**Convective Heat and Mass Transfer**  
**Prof. A. W. Date**  
**Department of Mechanical Engineering**  
**Indian Institute of Technology, Bombay**

**Module No.# 01**  
**Lecture No. # 41**  
**Natural Convection BLs**

So far we have considered heat and mass transfer from a wall, essentially, in force convection situations. The purpose of today's lecture is to consider heat and mass transfer from a wall under natural convection conditions. Natural convection is of importance both in practical equipments as well as in the environment, and therefore, student of convective heat and mass transfer should also know something about natural convection heat transfer as well as mass transfer.

(Refer Slide Time: 01:04)

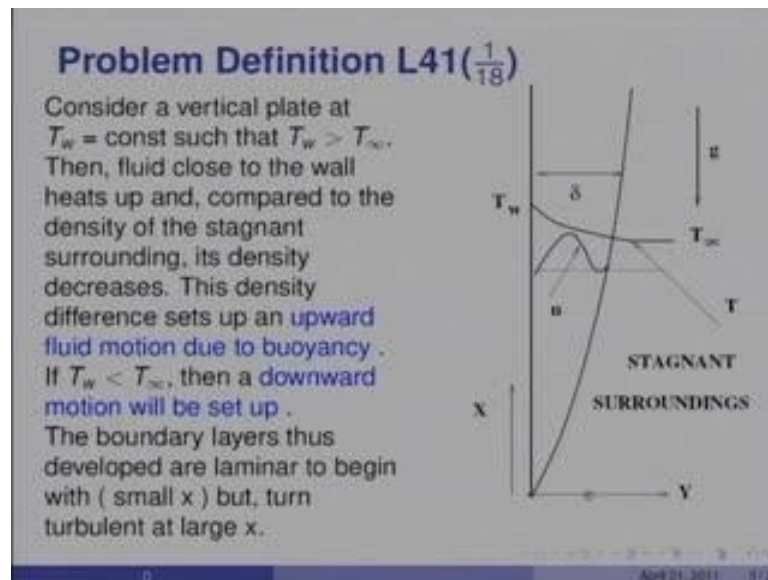

So, the topics for today are, first of all I will define the problem of natural convection passed a vertical wall, then I will develop constant property laminar boundary layer solutions using similarity method, in which initially we shall assume that the vertical wall is at constant wall temperature and there is no suction or blowing. But then, we shall

allow for variation of wall temperature as well as, allow for study the effect of suction and blowing.

Likewise, we will also develop integral solutions of laminar boundary layers and also of turbulent boundary layers. And finally, we shall consider simultaneous heat and mass transfer in a natural convection boundary layer, because natural convection can arise both due to temperature differences between the wall and the surroundings, as well as concentration differences between the wall and the surroundings. These differences setup forces which are opposed by gravity, and therefore, both buoyancy due to concentration difference and buoyancy due to a temperature difference are of importance.

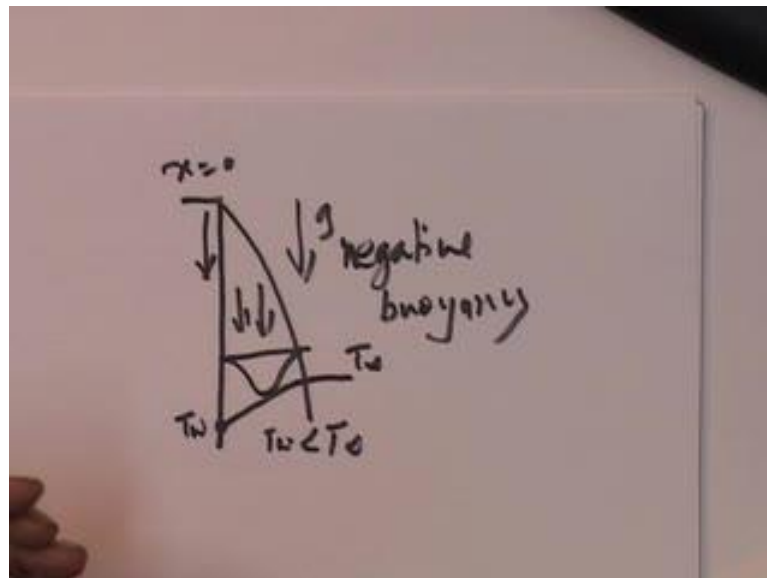

(Refer Slide Time: 02:30)

So, let us go to the problem definition, so as I have shown here, consider a vertical wall or a vertical plate which is at a constant wall temperature  $T_w$ , and let us for the time being, suppose, that  $T_w$  is greater than  $T_\infty$ , where  $T_\infty$  is the temperature of the stagnant surroundings. As a result, the fluid close to the wall will have a smaller density because it heats up, and compare to density of the stagnant surrounding, the density in this part would be smaller. And as long as the temperature difference persists between  $T$  and  $T_\infty$ , there would be a density difference and this density difference would drive the flow up against the gravity force.

The density difference sets up an upward flow, so the flow would come in here, and at  $x$  equal to 0, there would be 0 boundary layer thickness. But as  $x$  moves up, the boundary layer would grow of course, assuming a velocity profile which is something of this type. Notice the difference between a forced convection boundary layer and a natural convection boundary layer, in both the velocity is 0 of course, at the wall, but in natural convection boundary layers, the velocity peaks somewhere between the edge of the layer and the wall, and the velocity again falls down to 0 at the edge of the boundary layer. And that is because, there are no temperature differences beyond that point, and therefore, there is no driving force for the velocity and the velocity assumes the value of the stagnant surroundings which is 0.

(Refer Slide Time: 04:40)

If I have a  $T_w$  was less than  $T_\infty$ , then natural convection would be as I am showing here now, the natural convection flow will be like that and the velocity profile would be like so, and the temperature profile would go something like that  $T_w$  being less than  $T_\infty$ . And then, we would measure  $x$  equal to 0 here and downwards, so this is the negative buoyancy if you like, with  $g$  acting in that direction.

(Refer Slide Time: 02:30)

### Problem Definition L41( $\frac{1}{18}$ )

Consider a vertical plate at  $T_w = \text{const}$  such that  $T_w > T_\infty$ . Then, fluid close to the wall heats up and, compared to the density of the stagnant surrounding, its density decreases. This density difference sets up an **upward fluid motion due to buoyancy**. If  $T_w < T_\infty$ , then a **downward motion will be set up**. The boundary layers thus developed are laminar to begin with (small  $x$ ) but, turn turbulent at large  $x$ .

The boundary layers thus develop a laminar to begin with, but beyond the certain length the boundary layer becomes unstable and turns turbulence. So, there is actually a transition somewhere, and then, the boundary layer becomes turbulent.

(Refer Slide Time: 05:40)

### Governing Eqns - 1 L41( $\frac{2}{18}$ )

For constant properties, the governing eqns are

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

$$\rho \left[ u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right] = \frac{dp_\infty}{dx} + \mu \frac{\partial^2 u}{\partial y^2} - \rho g$$

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2}$$

where from hydrostatics,  $dp_\infty/dx = -\rho_\infty g$ . Now, using definition of volumetric coefficient of thermal expansion  $\beta$ , the vertical momentum eqn transforms to

$$\beta = -\frac{1}{\rho} \left( \frac{\rho - \rho_\infty}{T - T_\infty} \right)$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2} + g \beta (T - T_\infty)$$

So, to begin with let us consider only the laminar boundary layer. So, for a constant properties the governing equations would be the mass conservation or the continuity equation  $u \frac{du}{dx} + v \frac{du}{dy} = 0$ ,  $\rho \left( u \frac{du}{dx} + v \frac{du}{dy} \right) = \mu \frac{d^2 u}{dy^2} - \rho g$  which are the convection terms. There would be pressure gradient  $\mu \frac{d^2 u}{dy^2}$ ,

which is the boundary layer approximation, we are saying that there is **no** diffusion in the axial direction. And minus rho g is the body force due to gravity, likewise there would be temperature equation or the energy equation in its familiar boundary layer form.

Now, from hydrostatics  $\frac{dp}{dx}$  would be minus rho g, because a pressure gradient would be simply balance by the gravity.

(Refer Slide Time: 06:45)

$$\begin{aligned} -\frac{dp}{dx} - \rho g &= (\rho_0 - \rho)g = \frac{\rho \beta g (T - T_0)}{\rho} \\ \beta &= -\frac{1}{\rho} \frac{(\rho - \rho_0)}{(T - T_0)} \end{aligned}$$

So, therefore,  $\frac{dp}{dx} - \rho g$  will become equal to, sorry, this should be minus  $\frac{dp}{dx} - \rho g$ , and therefore, this will become rho g minus rho g.

(Refer Slide Time: 05:40)

**Governing Eqns - 1 L41( $\frac{2}{18}$ )**  
 For constant properties, the governing eqns are

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

$$\rho \left[ u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right] = \frac{dp_{\infty}}{dx} + \mu \frac{\partial^2 u}{\partial y^2} - \rho g$$

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2}$$

where from hydrostatics,  $dp_{\infty}/dx = -\rho_{\infty} g$ . Now, using definition of volumetric coefficient of thermal expansion  $\beta$ , the vertical momentum eqn transforms to

$$\beta = -\frac{1}{\rho} \left( \frac{\rho - \rho_{\infty}}{T - T_{\infty}} \right)$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2} + g \beta (T - T_{\infty})$$

Now, if I defined the beta - the coefficient of thermal expansion - as 1 over rho into rho minus rho infinity divided by T minus T infinity, then you can see that this term rho infinity minus rho g can be written as rho times beta, this will become rho times beta g T minus T infinity, and that is what I have written here. So, notice the small error here that the pressure gradient should be minus d p d rho infinity by d x.

So, if I define beta equal to minus 1 over rho rho minus rho infinity over T minus T infinity, then these 2 terms would transform to g beta and divide through by density, then you will have the momentum equation with nu d 2 u by d y square plus g beta T minus T infinity, this is called the buoyancy force term. So, our equations now are the continuity equation, the energy equation and the momentum equation with this. And you can see there is a clear coupling between energy equation and the momentum equation through the buoyancy term.

(Refer Slide Time: 08:33)

### Governing Eqns - 2 L41( $\frac{3}{18}$ )

Thus, the modified momentum eqn and the energy eqn must be solved simultaneously along with the continuity eqn. Solutions can be obtained by similarity, integral or finite-difference methods. The Integral forms of Eqns can be derived as

$$\frac{d}{dx} \left( \int_0^\delta u^2 dy \right) = -\frac{\tau_w}{\rho} + g \beta \int_0^\delta (T - T_\infty) dy$$

$$\frac{d}{dx} \left\{ \int_0^\delta u (T - T_\infty) dy \right\} = \frac{q_w}{\rho c_p}$$

The BCs are: at  $y = 0$ ,  $u = 0$  and  $T = T_w$ . At  $y = \delta$ ,  $u = 0$  and  $T = T_\infty$ .

Thus, the modified form of the momentum equation and the energy equation must be solved simultaneously along with the continuity equation. Solutions can be obtained by similarity integral or finite difference methods as in force convection, now the integral form of the equations can be derived as follows.

(Refer Slide Time: 05:40)

### Governing Eqns - 1 L41( $\frac{2}{18}$ )

For constant properties, the governing eqns are

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

$$\rho \left[ u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right] = \frac{dp_\infty}{dx} + \mu \frac{\partial^2 u}{\partial y^2} - \rho g$$

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2}$$

where from hydrostatics,  $dp_\infty/dx = -\rho_\infty g$ . Now, using definition of volumetric coefficient of thermal expansion  $\beta$ , the vertical momentum eqn transforms to

$$\beta = -\frac{1}{\rho} \left( \frac{\rho - \rho_\infty}{T - T_\infty} \right)$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2} + g \beta (T - T_\infty)$$

For example, I can write the left hand side of this in conserved property form as  $d u^2$  by  $d x$  plus  $d v u$  by  $d y$  equal to all that. And if I integrate each term from 0 to delta, then you will see that you will get  $d$  by  $d x$  0 to delta  $u^2 dy$ , which will be

the which will follow from the first term. This term which will be  $\frac{d}{dx} \int_0^\delta u^2 dy$  would of course, go to 0, both at  $y$  equal to  $\delta$ , where  $u$  is equal to 0 as well as at the wall where  $u$  is equal to 0, and therefore, the term would simply vanish.

This term would be  $\rho \frac{d}{dx} \int_0^\delta u^2 dy$  at  $y$  equal to  $\delta$  minus  $\rho \frac{d}{dx} \int_0^0 u^2 dy$  at  $y$  equal to 0, and that would be since  $\frac{d}{dx} \int_0^\delta u^2 dy$  at  $y$  equal to  $\delta$  is 0, you will simply get this as minus  $\tau_{\text{wall}}$  by  $\rho$  plus  $g \beta \int_0^\delta (T - T_\infty) dy$ .

(Refer Slide Time: 08:33)

**Governing Eqns - 2 L41( $\frac{3}{18}$ )**

Thus, the modified momentum eqn and the energy eqn must be solved simultaneously along with the continuity eqn. Solutions can be obtained by similarity, integral or finite-difference methods. The Integral forms of Eqns can be derived as

$$\frac{d}{dx} \left( \int_0^\delta u^2 dy \right) = -\frac{\tau_w}{\rho} + g \beta \int_0^\delta (T - T_\infty) dy$$

$$\frac{d}{dx} \left\{ \int_0^\delta u (T - T_\infty) dy \right\} = \frac{q_w}{\rho c_p}$$

The BCs are: at  $y = 0$ ,  $u = 0$  and  $T = T_w$ . At  $y = \delta$ ,  $u = 0$  and  $T = T_\infty$ .

Likewise, if I write this left hand side in conserved property form as  $\frac{d}{dx} \int_0^\delta u^2 dy$  plus  $\frac{d}{dx} \int_0^\delta u(T - T_\infty) dy$  and integrate from 0 to  $\delta$ , then I will get  $\frac{d}{dx} \int_0^\delta u^2 dy$  equal to 0 to  $\delta$   $u$  into  $T$  minus  $T_\infty$   $dy$  equal to  $q_{\text{wall}}$  over  $\rho c_p$ . And the boundary conditions are at  $y$  equal to 0,  $u$  is equal to 0 and  $T$  is equal to  $T_{\text{wall}}$  at  $y$  equal to  $\delta$ ,  $u$  is equal to again 0 and  $T$  is equal to  $T_\infty$ .

So, this would be the integral forms of equations, we shall take up these equations when we come to solution, but presently let us turn to solving the equations of this slide by similarity method.

(Refer Slide Time: 10:50)

**Similarity Soln - L41( $\frac{4}{18}$ )**

Define  $u \equiv \frac{\partial \Psi}{\partial y}$ ,  $v \equiv -\frac{\partial \Psi}{\partial x}$ ,  $\theta = \frac{T - T_\infty}{T_w - T_\infty}$  Then,

$$\frac{\partial \Psi}{\partial y} \frac{\partial^2 \Psi}{\partial y \partial x} - \frac{\partial \Psi}{\partial x} \frac{\partial^2 \Psi}{\partial y^2} = \nu \frac{\partial^3 \Psi}{\partial y^3} + g \beta (T_w - T_\infty) \theta \quad (\text{MOM})$$

$$\frac{\partial \Psi}{\partial y} \frac{\partial \theta}{\partial x} - \frac{\partial \Psi}{\partial x} \frac{\partial \theta}{\partial y} = \alpha \frac{\partial^2 \theta}{\partial y^2} - \theta \frac{\partial \Psi}{\partial y} \frac{dT_w}{dx} \quad (\text{Energy})$$

Now, define similarity variables  $\eta = y \times S(x)$  and  $\Psi(x, \eta) = \nu \times f(\eta) \times G(x)$ . Hence,

$$f''' + \left[ \frac{g \beta (T_w - T_\infty)}{(G S^3) \nu^2} \right] \theta + \left( \frac{G}{S} \right) (f f'' - f'^2) - \left( \frac{G}{S^2} \right) S' f'^2 = 0$$

$$\theta'' + Pr \left[ \left( \frac{G}{S} \right) f \theta' - \left( \frac{G/S}{T_w - T_\infty} \frac{dT_w}{dx} \right) f \theta \right] = 0$$

So, as usual we defined stream function u equal to d psi by d y, and v equal to minus d psi by d x, and we define a dimensionless temperature T minus T infinity divided by Twall minus T infinity, the denominator being constant given constant.

And then, the momentum equation simply would become, this is u d psi by d y into d u by d x which is d 2 psi by d y d x minus d psi by d x, which is v, into d u by d y, which is d 2 psi by d y square, plus nu times d 2 u by d y square which will be d 3 psi be d y cube plus g beta T w minus T infinity into theta and that could be the momentum equation. And likewise, this would be the energy equation, d psi by d y d theta by d x minus d psi by d y d theta by d y equal to alpha d 2 theta by d y square minus theta d psi by d y d Twall by d x.

Now, this term arises out of the u d t by d x term when T w minus T infinity, I have retained this term at the movement, because later on we are going to consider the case in which Twall itself would vary with x, but presently **if T w is 0 then of course - i mean T w is constant then of course, that term would be 0.**

We shall define as usual similarity variables eta equal to y multiplied by stretching function S x and stream function psi x eta equal to nu times f eta into G x another function of x. Then, if we substitute in this, then you will get f triple prime g beta T w minus T infinity G s cube nu square theta plus G dash by s f f double prime minus f dash

square minus  $G$  by  $S$  square  $S$  dash  $f$  dash square equal to 0. Now, of course,  $f$  dash is here are all derivatives with respect to  $\eta$  and  $G$  dash and  $S$  dash are derivatives with respect to  $x$ .

Similarly, the energy equation would read in like this  $\theta$  double prime plus  $\text{Prandtl}$  into  $G$  dash by  $S$   $f$   $\theta$  prime minus  $G$  by  $S$   $T_w$  minus  $T_\infty$  over  $d$   $T_w$  minus  $d$   $x$  into  $f$  dash  $\theta$  equal to 0. Again the two equations are coupled because  $\theta$  appears in the momentum equation and likewise  $f$  appears in the energy equation. These equations can be solved by similarity method, if all these factors which I have shown are absolute constant.

Remember,  $G$  is a function of  $x$ ,  $S$  is also a function of  $x$   $T_w$  minus  $T_\infty$  can also be a function of  $x$ , but the group as a whole must be a constant. Likewise,  $G$  dash divided by  $S$  must also be a constant and  $G$  by  $S$  square into  $S$  dash must also be a constant for similarity solutions to exist, likewise  $G$  by  $S$   $T_w$  minus  $T_\infty$   $d$   $T_w$  by  $d$   $x$  must also be an absolute constant.

Only when all these factors are absolute constants, we would get two perfect ordinary differential equations which is the requirement for obtaining similarity solution. So, let us see, what do these conditions of constant  $c$  imply, which would give us **these** as a function of  $x$  as well as  $g$  as a function of  $x$ .

(Refer Slide Time: 14:38)

**Similarity Soln -  $T_w = \text{const}$  - L41( $\frac{5}{18}$ )**

- For  $dT_w/dx = 0$ , let
 
$$\frac{G}{S} = C_1, \quad \frac{g \beta (T_w - T_\infty)}{(G S^2 \nu^2)} = C_2 \quad \text{and} \quad \frac{G S'}{S^2} = C_3$$
- Combining expressions for  $C_1$  and  $C_2$  gives  
 $G(x) \propto x^{3/4}$  and  $S(x) \propto x^{-1/4}$
- If we take  $C_3 = -1$  then,  $C_1 = 3$  and  $C_2 = 1$ . Hence,  
 $G = 4 \times (Gr_x/4)^{1/4}$  and  $S = (Gr_x/4)^{1/4}/x$ , where
 
$$Gr_x = \frac{g \beta (T_w - T_\infty) x^3}{\nu^2} = \text{(Grashof Number)}$$
 and
 
$$f'' + \theta + 3ff'' - 2f'^2 = 0 \quad \text{BCs } f(0) = f'(0) = f(\infty) = 0$$

$$\theta'' + 3Prf\theta' = 0 \quad \text{BCs } \theta(0) = 1, \theta(\infty) = 0$$

$$\eta = \frac{y}{x} \left(\frac{Gr_x}{4}\right)^{1/4} \quad f' = \frac{u x/\nu}{2\sqrt{Gr_x}}$$

So, let us first consider  $d T_w$  by  $d x$  equal to 0, and let  $G$  dash by  $s$  equal to  $C_1 g \beta (T_w - T_\infty)$  divided by  $G S^3 \nu^2$  equal to  $C_2$  and  $G S$  dash by  $S^2$  is equal to  $C_3$ .

(Refer Slide Time: 10:50)

**Similarity Soln - L41( $\frac{4}{18}$ )**

Define  $u \equiv \frac{\partial \Psi}{\partial y}$ ,  $v \equiv -\frac{\partial \Psi}{\partial x}$ ,  $\theta = \frac{T - T_\infty}{T_w - T_\infty}$ . Then,

$$\frac{\partial \Psi}{\partial y} \frac{\partial^2 \Psi}{\partial y \partial x} - \frac{\partial \Psi}{\partial x} \frac{\partial^2 \Psi}{\partial y^2} = \nu \frac{\partial^3 \Psi}{\partial y^3} + g \beta (T_w - T_\infty) \theta \quad (\text{Momentum})$$

$$\frac{\partial \Psi}{\partial y} \frac{\partial \theta}{\partial x} - \frac{\partial \Psi}{\partial x} \frac{\partial \theta}{\partial y} = \alpha \frac{\partial^2 \theta}{\partial y^2} - \theta \frac{\partial \Psi}{\partial y} \frac{dT_w}{dx} \quad (\text{Energy})$$

Now, define similarity variables  $\eta = y \times S(x)$  and  $\Psi(x, \eta) = \nu \times f(\eta) \times G(x)$ . Hence,

$$f''' + \left[ \frac{g \beta (T_w - T_\infty)}{(G S^3) \nu^2} \right] \theta + \left( \frac{G}{S} \right) (f f'' - f'^2) - \left( \frac{G}{S^2} \right) S' f'^2 = 0$$

$$\theta'' + Pr \left[ \left( \frac{G}{S} \right) f \theta' - \left( \frac{G/S}{T_w - T_\infty} \frac{dT_w}{dx} \right) f \theta \right] = 0$$

April 21, 2011 6:28

In other words, what I have done is, I have said this is  $C_1$ , this is  $C_2$  and this is  $C_3$ , this whole term is  $C_3 d T_w$  by  $d x$  is 0, and therefore, that whole term is 0 in the present case.

(Refer Slide Time: 14:38)

**Similarity Soln -  $T_w = \text{const}$  - L41( $\frac{5}{18}$ )**

● For  $d T_w / dx = 0$ , let

$$\left( \frac{G}{S} \right) = C_1, \quad \frac{g \beta (T_w - T_\infty)}{(G S^3) \nu^2} = C_2 \quad \text{and} \quad \frac{G S'}{S^2} = C_3$$

● Combining expressions for  $C_1$  and  $C_2$  gives  $G(x) \propto x^{3/4}$  and  $S(x) \propto x^{-1/4}$

● If we take  $C_3 = -1$  then,  $C_1 = 3$  and  $C_2 = 1$ . Hence,  $G = 4 \times (Gr_x/4)^{1/4}$  and  $S = (Gr_x/4)^{1/4} / x$ , where

$$Gr_x = \frac{g \beta (T_w - T_\infty) x^3}{\nu^2} = (\text{Grashof Number}) \quad \text{and}$$

$$f''' + \theta + 3 f f'' - 2 f'^2 = 0 \quad \text{BCs } f(0) = f'(0) = f(\infty) = 0$$

$$\theta'' + 3 Pr f \theta' = 0 \quad \text{BCs } \theta(0) = 1, \theta(\infty) = 0$$

$$\eta = \frac{y}{x} \left( \frac{Gr_x}{4} \right)^{1/4} \quad f' = \frac{u x / \nu}{2 \sqrt{Gr_x}}$$

April 21, 2011 7:28

Now, combining expressions for C 1 and C 2 gives that G x should be proportional to x raise to 3 by 4 and S x should be proportional to x raise to minus 1 by 4. So, therefore, if we said quite arbitrarily, C 3 equal to minus 1, then it would follow that C 1 equal to 3 and C 2 equal to 1. Now, there is a little algebra here of over 1 page to show all this. And hence, G function would be 4 times grass of number based on x divided by 4 raise to a quarter. And S will be again grass of number divided by 4 raised quarter divided by x, where the grass of number as you know is defined in this fashion g beta T w minus T infinity x cube nu square.

Remember, here T w minus T infinity is constant, and then the momentum equation would read as f triple prime plus theta plus 3 f f double prime minus 2 f dash square equal to 0 theta double prime plus 3 prandtl f theta dash equal to 0, this will be the energy equation. And the boundary conditions would be f 0 equal to f dash 0 which is the velocity, f dash 0 is velocity, f dash infinity would be 0. So, all these are 0's and f 0 equal to 0 implies that v at the wall is also 0. And the boundary conditions of theta would be from its definition theta 0 would be 1 and theta infinity equal to 0.

The similarity variable eta which was y into s x would be y divided by x as you can see here into grass of x divided by 1 raise to 1 by 4 and f dash will give us the velocity u x divided by nu divided by 2 root G r x. Now, how are these equations to be solved? **One can**, these are coupled equations mind you, so they have to be solve simultaneously.

(Refer Slide Time: 17:32)

**Soln ( Contd ) - 1 - L41( $\frac{6}{18}$ )**  
 Unlike in Forced convection, the equations are best solved by FD method using Tri-Diagonal Matrix Algorithm.

$$\frac{f_i - f_{i-1}}{\Delta \eta} = f'_i$$

$$(AE + AW) f'_i = AE f'_{i+1} + AW f'_{i-1} + \theta_i \text{ where}$$

$$AE = \left( \frac{1}{\Delta \eta^2} + 1.5 \frac{f_i}{\Delta \eta} \right) \text{ and } AW = \left( \frac{1}{\Delta \eta^2} - 1.5 \frac{f_i}{\Delta \eta} \right)$$

$$(AE + AW) \theta_i = AE \theta_{i+1} + AW \theta_{i-1} \text{ where}$$

$$AE = \left( \frac{1}{\Delta \eta^2} + 1.5 Pr \frac{f_i}{\Delta \eta} \right) \text{ and } AW = \left( \frac{1}{\Delta \eta^2} - 1.5 Pr \frac{f_i}{\Delta \eta} \right)$$

$$\theta'(0) = 2 \times \left( \frac{\theta(2) - \theta(1)}{\Delta \eta} \right) \text{ and } f''(0) = 2 \times \left( \frac{f'(2) - f'(1)}{\Delta \eta} \right)$$

$$\text{Soln: } Nu_x = \frac{q_w}{T_w - T_\infty} \left( \frac{x}{k} \right) = -\theta'(0) \times (Gr_x/4)^{1/4}$$

Now, of course, like in force convection, we solved equations of this type by what was called shooting method, but it turns out to be little bit unstable when we consider natural convection. And therefore, unlike in force convection the equations are best solved by finite difference method using what is called as a tri-diagonal matrix algorithm, which you must have studied in your numerical analysis class.

(Refer Slide Time: 17:56)

So, very simply what I does is that the momentum equation which is  $f''' + 3ff'' - 2f'^2 + \theta = 0$ . So, I can write this as  $\frac{d^3 f}{d\eta^3} + 3f \frac{d^2 f}{d\eta^2} - 2 \left(\frac{df}{d\eta}\right)^2 + \theta = 0$ .

And likewise, I can say the energy equation is  $\frac{d^2 \theta}{d\eta^2} + 3Pr f \frac{d\theta}{d\eta} = 0$  and  $f'$  is nothing but  $\frac{df}{d\eta}$ . So, what I do is, I solve for  $f$ , from which I get  $f'$  and then, I solve this equation - this second order equation - in  $f'$  by finite difference method and this again by finite difference method.

(Refer Slide Time: 17:32)

**Soln (Contd) - 1 - L41( $\frac{6}{18}$ )**  
 Unlike in Forced convection, the equations are best solved by FD method using Tri-Diagonal Matrix Algorithm.

$$\frac{f_i - f_{i-1}}{\Delta \eta} = f_i'$$

$$(AE + AW) f_i = AE f_{i+1} + AW f_{i-1} + \theta_i \text{ where}$$

$$AE = \left( \frac{1}{\Delta \eta^2} + 1.5 \frac{f_i}{\Delta \eta} \right) \text{ and } AW = \left( \frac{1}{\Delta \eta^2} - 1.5 \frac{f_i}{\Delta \eta} \right)$$

$$(AE + AW) \theta_i = AE \theta_{i+1} + AW \theta_{i-1} \text{ where}$$

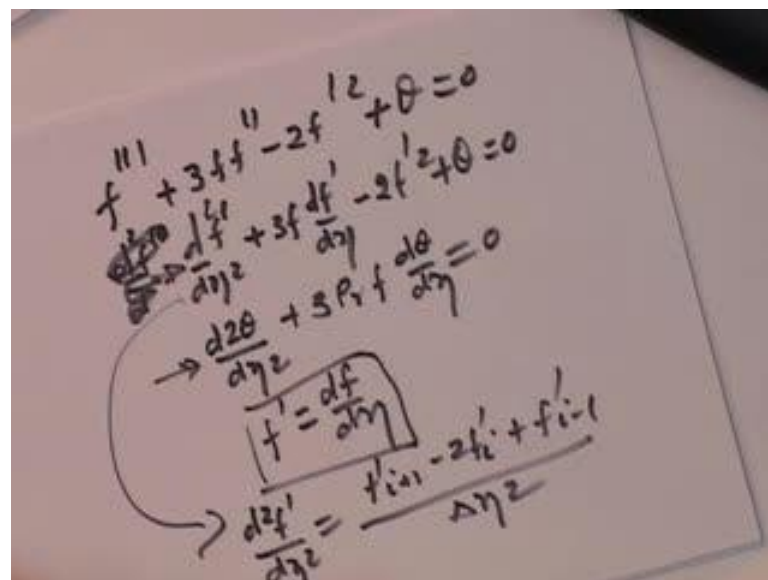

$$AE = \left( \frac{1}{\Delta \eta^2} + 1.5 Pr \frac{f_i}{\Delta \eta} \right) \text{ and } AW = \left( \frac{1}{\Delta \eta^2} - 1.5 Pr \frac{f_i}{\Delta \eta} \right)$$

$$\theta'(0) = 2 \times \left( \frac{\theta(2) - \theta(1)}{\Delta \eta} \right) \text{ and } f''(0) = 2 \times \left( \frac{f'(2) - f'(1)}{\Delta \eta} \right)$$

$$\text{Soln: } Nu_x = \frac{q_w}{T_w - T_\infty} \left( \frac{x}{k} \right) = -\theta'(0) \times (Gr_x/4)^{1/4}$$

So, that is what I have shown on this slide, so this is the equation  $\frac{df}{d\eta} = f_i'$  which will simply give, and we do  $\frac{df}{d\eta}$  is been represent by forward difference  $\frac{f_i - f_{i-1}}{\Delta \eta} = f_i'$ .

(Refer Slide Time: 19:48)

Then, if I turn to this equation **for the for** then,  $\frac{d^2f}{d\eta^2} = \frac{f_{i+1} - 2f'_i + f_{i-1}}{\Delta \eta^2}$  will be simply  $\frac{f_{i+1} - 2f'_i + f_{i-1}}{\Delta \eta^2}$ , and likewise  $\frac{df}{d\eta}$  and so on and so forth.

(Refer Slide Time: 17:32)

**Soln (Contd) - 1 - L41( $\frac{6}{18}$ )**  
 Unlike in Forced convection, the equations are best solved by FD method using Tri-Diagonal Matrix Algorithm.

$$\frac{f_i - f_{i-1}}{\Delta \eta} = f'_i$$

$$(AE + AW) f'_i = AE f'_{i+1} + AW f'_{i-1} + \theta_i \text{ where}$$

$$AE = \left( \frac{1}{\Delta \eta^2} + 1.5 \frac{f_i}{\Delta \eta} \right) \text{ and } AW = \left( \frac{1}{\Delta \eta^2} - 1.5 \frac{f_i}{\Delta \eta} \right)$$

$$(AE + AW) \theta_i = AE \theta_{i+1} + AW \theta_{i-1} \text{ where}$$

$$AE = \left( \frac{1}{\Delta \eta^2} + 1.5 Pr \frac{f_i}{\Delta \eta} \right) \text{ and } AW = \left( \frac{1}{\Delta \eta^2} - 1.5 Pr \frac{f_i}{\Delta \eta} \right)$$

$$\theta'(0) = 2 \times \left( \frac{\theta(2) - \theta(1)}{\Delta \eta} \right) \text{ and } f''(0) = 2 \times \left( \frac{f'(2) - f'(1)}{\Delta \eta} \right)$$

$$\text{Soln: } Nu_x = \frac{q_w}{T_w - T_\infty} \left( \frac{x}{k} \right) = -\theta'(0) \times (Gr_x/4)^{1/4}$$

So, if you do this finite difference representation of all the derivatives, we can derive an equation for  $f'_{i+1} + AW f'_i = AE f'_i + 1 + AW f'_{i-1} + \theta_i$ , where  $AE$  is equal to  $1/\Delta \eta^2 + 1.5 f_i/\Delta \eta$  by  $\Delta \eta$  and  $AW$  would be  $1/\Delta \eta^2 - 1.5 f_i/\Delta \eta$ . And likewise similarly, energy equation would be  $AE \theta_{i+1} + AW \theta_{i-1} = (AE + AW) \theta_i$  and in this case  $AE$  and  $AW$  would take those expression.

Now, this sort of equations that you see here, are perfectly suited for applying tri-diagonal matrix algorithm, because the diagonal element would always dominate over the neighboring elements - neighbouring coefficients  $AE$  and  $AW$ , whereas the diagonal element of the matrix would be  $AE + AW$ .

And therefore, one can get very, very, fast solutions; once the solutions are obtained our interest is to be obtained  $\theta'(0)$ , which is the temperature gradient at the wall, and that would be  $2 \times (\theta(2) - \theta(1))/\Delta \eta$  at  $\eta = 0$ . And likewise, if we want to get the resistance at the wall - frictional resistance at the wall - then, it will be  $f''(0) = 2 \times (f'(2) - f'(1))/\Delta \eta$ .

Now, the nusselt number of course, is  $q_{\text{wall}}$  divided by  $T_{\text{wall}} - T_{\infty}$  x by  $k$  the usual definition. And the  $q_{\text{wall}}$  over  $T_{\text{w}} - T_{\infty}$  would be simply minus  $\theta' (0)$   $Gr_x^{1/4}$ . So, once we have solved the temperature and  $f''$  and  $f$  distributions, we can readily obtain our nusselt number as well as the skin friction, we should be interested. Although in natural convection in generally, one is not really interested in skin friction at all, because there is no pumping power require in natural convection, and therefore, it is of only academic interest, because this simply represents the velocity gradient at the wall.

(Refer Slide Time: 22:49)

So, here are the solutions obtained for  $T_{\text{wall}}$  equal to constant and I have allowed for a range of prandtl numbers going from as low as 0.01 which is for liquid metals to as high as 1000 which is for viscous oils. Around 1 is the gases, and you can see the  $\eta_{\text{max}}$  required is about 7.5 as the prandtl number increases beyond 1, you can see that the boundary layer is thinner because, the temperature gradients occurs much more rapidly near the wall.

And therefore, you need  $\eta_{\text{max}}$  as to be shorten through about 1 at 1000 whereas, you know in the liquid metal side, you get a thicker boundary layer and  $\eta$  is of the order of 22. And here are the temperature profiles. For example, you can see that this is the distribution of velocity  $f''$  and this is for prandtl equal to 0.1, 1, 10, 100 and 1000. In dimensionless form  $f'' \eta$ , whereas this is  $\theta$  versus  $\eta$ , and you can see for 0.1

you are going right up to almost eta of nearly 12 whereas, as the prandtl number increases the boundary layer thickness reduces as you can see.

The nusselt number on the other hand or nusselt number divided by grash of raise to 0.25 is 0.059 at 0.1, 0.164 at 0.1, 0.402 for 1 and 0.821 at 10 and 1.54 at 100 and 2.72 at 1000.  $f''(0)$  of course, goes on reducing as you increase the prandtl number. But as I said earlier, our main interest is not in  $f''(0)$ , it is of academic interest, the main thing is the nusselt number, the manner in which nusselt number varies.

(Refer Slide Time: 25:16)

**Soln for  $T_w - T_\infty = A x^n$  - L41( $\frac{8}{18}$ )**  
 Governing eqns for  $T_w - T_\infty = A x^n$  are

$$f'' + (n+3) f f' - (2n+2) f'^2 + \theta = 0$$

$$\theta'' + Pr \{ (n+3) f \theta' - 4 n f' \theta \} = 0$$

**Solns for  $n = 0.2$  and  $n = 1.0$**

n	Pr	0.01	0.1	1.0	10	100	1000
0.2	$\frac{Nu_x}{Gr_x^{0.25}}$	0.068	0.189	0.457	0.924	1.705	3.03
	$f''(0)$	0.934	0.813	0.607	0.391	0.230	0.13
1.0	$\frac{Nu_x}{Gr_x^{0.25}}$	0.093	0.354	0.597	1.184	2.178	3.87
	$f''(0)$	0.807	0.702	0.523	0.336	0.197	0.11

For  $n = 0.2$ ,  
 $q_w = -k (T_w - T_\infty) \theta'(0) S \propto (T_w - T_\infty)^{1.25} \times x^{-0.25} = \text{const.}$   
 The  $Nu_x$  values are greater than those for  $T_w = \text{const.}$

Now, similarity solutions are also possible when  $T_w - T_\infty$  varies as  $A X^n$  to the power of n.

(Refer Slide Time: 10:50)

**Similarity Soln - L41( $\frac{4}{18}$ )**

Define  $u \equiv \frac{\partial \Psi}{\partial y}$ ,  $v \equiv -\frac{\partial \Psi}{\partial x}$ ,  $\theta = \frac{T - T_\infty}{T_w - T_\infty}$ . Then,

$$\frac{\partial \Psi}{\partial y} \frac{\partial^2 \Psi}{\partial y \partial x} - \frac{\partial \Psi}{\partial x} \frac{\partial^2 \Psi}{\partial y^2} = \nu \frac{\partial^3 \Psi}{\partial y^3} + g \beta (T_w - T_\infty) \theta \quad (\text{Momentum})$$

$$\frac{\partial \Psi}{\partial y} \frac{\partial \theta}{\partial x} - \frac{\partial \Psi}{\partial x} \frac{\partial \theta}{\partial y} = \alpha \frac{\partial^2 \theta}{\partial y^2} - \theta \frac{\partial \Psi}{\partial y} \frac{dT_w}{dx} \quad (\text{Energy})$$

Now, define similarity variables  $\eta = y \times S(x)$  and  $\Psi(x, \eta) = \nu \times f(\eta) \times G(x)$ . Hence,

$$f''' + \left[ \frac{g \beta (T_w - T_\infty)}{(G S^3) \nu^2} \right] \theta + \left( \frac{G}{S} \right) (f f'' - f'^2) - \left( \frac{G}{S^2} \right) S' f'^2 = 0$$

$$\theta'' + Pr \left[ \left( \frac{G}{S} \right) f \theta' - \left( \frac{G/S}{T_w - T_\infty} \frac{dT_w}{dx} \right) f \theta \right] = 0$$

April 21, 2011 9:28

Remember, now this term which was set to 0 would be finite and if  $T_w - T_\infty$  varies as  $A x^n$  to the power of  $n$ , then this term would also be constant.

(Refer Slide Time: 25:16)

**Soln for  $T_w - T_\infty = A x^n$  - L41( $\frac{8}{18}$ )**

Governing eqns for  $T_w - T_\infty = A x^n$  are

$$f''' + (n+3) f f'' - (2n+2) f'^2 + \theta = 0$$

$$\theta'' + Pr \left\{ (n+3) f \theta' - 4 n f' \theta \right\} = 0$$

**Solns for  $n = 0.2$  and  $n = 1.0$**

n	Pr	0.01	0.1	1.0	10	100	1000
0.2	$\frac{Nu_x}{Gr_x^{1/2}}$	0.068	0.189	0.457	0.924	1.705	3.03
	$f''(0)$	0.934	0.813	0.607	0.391	0.230	0.13
1.0	$\frac{Nu_x}{Gr_x^{1/2}}$	0.093	0.354	0.597	1.184	2.178	3.87
	$f''(0)$	0.807	0.702	0.523	0.336	0.197	0.11

For  $n = 0.2$ ,  
 $q_w = -k (T_w - T_\infty) \theta'(0) S \propto (T_w - T_\infty)^{1-0.25} \times x^{-0.25} = \text{const}$ .  
 The  $Nu_x$  values are greater than those for  $T_w = \text{const}$ .

April 21, 2011 16:28

And the governing equations would then look like this,  $f''' + n + 3 f f'' - (2n + 2) f'^2 + \theta = 0$ . And  $\theta'' + Pr \{ (n + 3) f \theta' - 4 n f' \theta \} = 0$ . Now, you can see, if I set  $n$  equal to 0 which would be the constant temperature case, then the previous equations are readily recovered.

I am considering two values of n, n equal to 2 and n equal to 1; n equal to 1 of course, implies linear variation of temperature, but n equal to 2 has a very special significance. As you can see, for n equal to 2, if I write q wall will be equal to minus k T w minus T infinity theta prime 0 into S, and S itself is proportional to x to the power of 0.25, as you will recall from here.

(Refer Slide Time: 14:38)

**Similarity Soln -  $T_w = \text{const}$  - L41( $\frac{5}{18}$ )**

- For  $dT_w/dx = 0$ , let
 
$$\left(\frac{G}{S}\right) = C_1, \quad \frac{g \beta (T_w - T_\infty)}{(G S^3 \nu^2)} = C_2 \quad \text{and} \quad \frac{G S'}{S^2} = C_3$$
- Combining expressions for  $C_1$  and  $C_2$  gives
 
$$G(x) \propto x^{3/4} \quad \text{and} \quad S(x) \propto x^{-1/4}$$
- If we take  $C_3 = -1$  then,  $C_1 = 3$  and  $C_2 = 1$ . Hence,
 
$$G = 4 \times (Gr_x/4)^{1/4} \quad \text{and} \quad S = (Gr_x/4)^{1/4}/x$$
, where
 
$$Gr_x = \frac{g \beta (T_w - T_\infty) x^3}{\nu^2} = \text{(Grashof Number)}$$
 and
 
$$f'' + \theta + 3ff'' - 2f'^2 = 0 \quad \text{BCs } f(0) = f'(0) = f(\infty) = 0$$

$$\theta'' + 3Prf\theta' = 0 \quad \text{BCs } \theta(0) = 1, \theta(\infty) = 0$$

$$\eta = \frac{y}{x} \left(\frac{Gr_x}{4}\right)^{1/4} \quad f' = \frac{u x/\nu}{2\sqrt{Gr_x}}$$

(Refer Slide Time: 25:16)

**Soln for  $T_w - T_\infty = A x^n$  - L41( $\frac{8}{18}$ )**

Governing eqns for  $T_w - T_\infty = A x^n$  are

$$f'' + (n+3)ff'' - (2n+2)f'^2 + \theta = 0$$

$$\theta'' + Pr \left\{ (n+3)f\theta' - 4nf'\theta \right\} = 0$$

Solns for  $n = 0.2$  and  $n = 1.0$

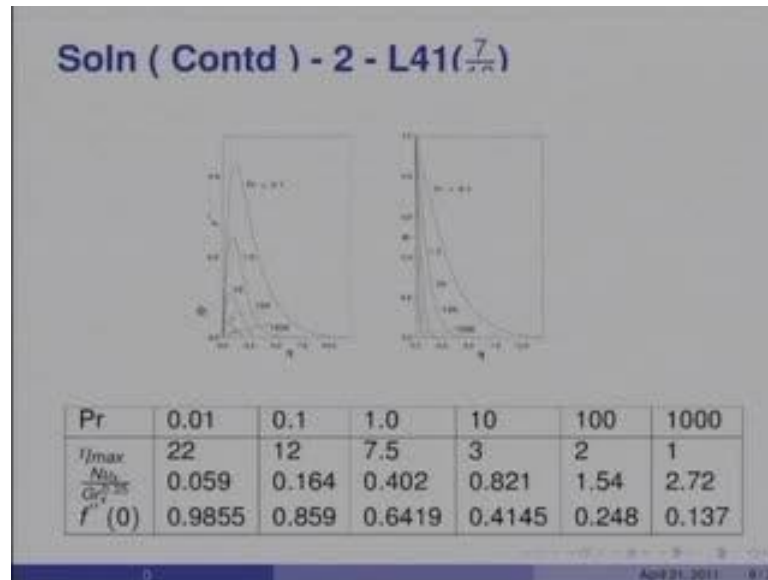

n	Pr	0.01	0.1	1.0	10	100	1000
0.2	$\frac{Nu_x}{Gr_x^{1/2}}$	0.068	0.189	0.457	0.924	1.705	3.03
	$f'(0)$	0.934	0.813	0.607	0.391	0.230	0.13
1.0	$\frac{Nu_x}{Gr_x^{1/2}}$	0.093	0.354	0.597	1.184	2.178	3.87
	$f'(0)$	0.807	0.702	0.523	0.336	0.197	0.11

For  $n = 0.2$ ,  
 $q_w = -k(T_w - T_\infty)\theta'(0)S \propto (T_w - T_\infty)^{1.25} \times x^{-0.25} = \text{const}$ .  
 The  $Nu_x$  values are greater than those for  $T_w = \text{const}$ .

As we said s x proportional to the minus 0.25, and here, if T w minus T infinity itself varies as 0.2 x to the power of 0.2, then further raise to 1.25 will give 0.25 x to the power

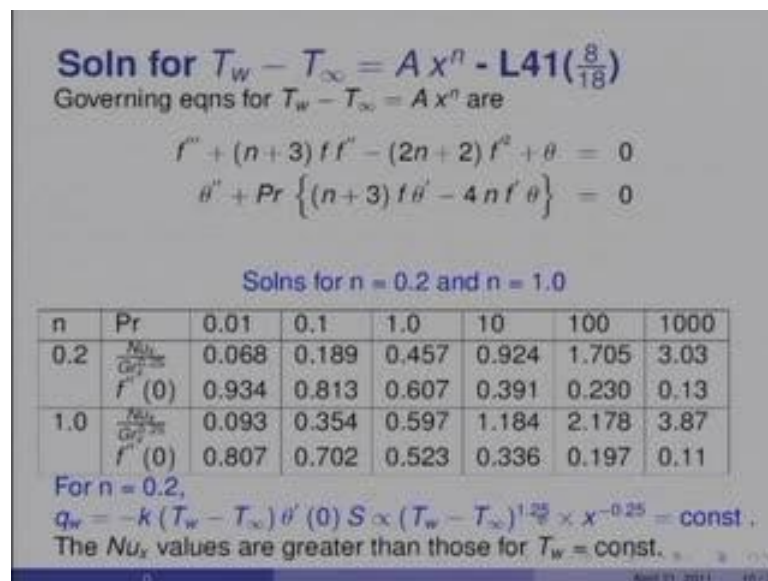

of 0.25 into  $x$  to the power of minus 0.25 and therefore, this would result into constant. And therefore,  $n$  equal to 0.2 represents the constant wall heat flux case, and therefore it is of interest. So, again, you will see the values of  $Nu_x$  divide by  $Gr_x^{0.25}$  or 0.068, 0.189, 0.457, 0.924, 1.705 and 3.03.

(Refer Slide Time: 22:49)

You will see, compare to  $T_w$  equal to constant case at all prandtl numbers  $q_w$  equal to constant gives you a higher nusselt number - a higher nusselt rate.

(Refer Slide Time: 25:16)

This is very much like what we had observed in forced convection laminar boundary layers as well. For linear case - linear temperature variation case - the nusselt number variation is again higher than n equal to 0.2, 0.093, 0.354, 0.597, 1.1842, 2.178 and 3.87. So, you can get very good solutions and these have usually been found to be in very good agreement with experimental data.

(Refer Slide Time: 28:16)

**Soln for  $T_w - T_\infty = A x^n$  &  $v_w$  - L41( $\frac{9}{18}$ )**  
 For finite  $v_w$ , boundary condition is changed

$$v = -\frac{\partial \Psi}{\partial x} = -\nu (f G' + G f' y S')$$
 hence
 
$$f(0) = -\frac{(v_w x / \nu)}{(Gr_x / 4)^{0.25}} \times \left(\frac{1}{n+3}\right) = \frac{-v_w^*}{n+3} = \text{const}$$

Solns for  $n = 0$  ( $T_w = \text{const}$ ) and  $Pr = 0.7$

	Suction			Blowing		
$v_w^*$	-3	-2	-1	+1	+2	+3
$Nu_x Gr_x^{-1/4}$	1.513	1.06	0.664	0.147	0.0504	0.0055
$f'(0)$	0.446	0.574	0.678	0.576	0.434	0.326

For  $v_w^* = 0$ ,  $Nu_x Gr_x^{-1/4} = 0.353$ .

Now, let us consider the effect of suction and blowing again in the presence of  $T_w - T_\infty$  varying as  $A x^n$ . Now,  $v$  is  $-\frac{d\Psi}{dx}$  and that would transform to  $-\nu (f G' + G f' y S')$ . And therefore, at  $y = 0$ , I would get the value of  $v_w$  and this would be  $f(0)$ . So,  $f(0)$  would be simply  $v_w$  divided by  $\nu G'$  and substituting for  $G'$  from the  $G(x)$  relationship, you will see  $f(0)$  is nothing but  $-\frac{v_w x}{\nu} \times \frac{1}{n+3}$  or simply  $-\frac{v_w^*}{n+3}$ , this is like a Reynolds number, so I can make it into  $-\frac{v_w^*}{n+3}$  and that could be a constant  $f_w$ .

(Refer Slide Time: 25:16)

**Soln for  $T_w - T_\infty = A x^n$  - L41( $\frac{8}{18}$ )**  
 Governing eqns for  $T_w - T_\infty = A x^n$  are

$$f'' + (n+3) f f'' - (2n+2) f'^2 + \theta = 0$$

$$\theta'' + Pr \{ (n+3) f \theta' - 4 n f' \theta \} = 0$$

**Solns for  $n = 0.2$  and  $n = 1.0$**

n	Pr	0.01	0.1	1.0	10	100	1000
0.2	$\frac{Nu_x}{Gr_x^{0.25}}$	0.068	0.189	0.457	0.924	1.705	3.03
	$f'(0)$	0.934	0.813	0.607	0.391	0.230	0.13
1.0	$\frac{Nu_x}{Gr_x^{0.25}}$	0.093	0.354	0.597	1.184	2.178	3.87
	$f'(0)$	0.807	0.702	0.523	0.336	0.197	0.11

For  $n = 0.2$ ,  
 $q_w = -k(T_w - T_\infty) \theta'(0) S \propto (T_w - T_\infty)^{1.25} \times x^{-0.25} = \text{const.}$   
 The  $Nu_x$  values are greater than those for  $T_w = \text{const.}$

(Refer Slide Time: 28:16)

**Soln for  $T_w - T_\infty = A x^n$  &  $v_w$  - L41( $\frac{9}{18}$ )**  
 For finite  $v_w$ , boundary condition is changed

$$v = -\frac{\partial \Psi}{\partial x} = -\nu (f G' + G f' y S') \text{ hence}$$

$$f(0) = -\frac{(v_w x / \nu)}{(Gr_x/4)^{0.25}} \times \left(\frac{1}{n+3}\right) = \frac{-v_w^*}{n+3} = \text{const}$$

**Solns for  $n = 0$  ( $T_w = \text{const}$ ) and  $Pr = 0.7$**

	Suction			Blowing		
$v_w^*$	-3	-2	-1	+1	+2	+3
$Nu_x Gr_x^{-1/4}$	1.513	1.06	0.664	0.147	0.0504	0.0055
$f'(0)$	0.446	0.574	0.678	0.576	0.434	0.326

For  $v_w^* = 0$ ,  $Nu_x Gr_x^{-1/4} = 0.353$ .

So, you solve the equations of the previous slide, you solve these equations with  $f(0)$  equal to minus  $V w^*$  over  $n n + 3$ , where  $n$  is specified as well as  $V w^*$  is specified. Now here, I am giving solutions for  $n$  equal to 0 which is the constant wall temperature case and taking prandtl equal to 0.7, only the two values. And you can see on the suction side  $V w^*$  would be negative, so  $V w^*$  very high suction rate goes on reducing, reducing, and this blowing rate  $V w^*$  positive 1, 2 and 3.

Then, you can see nusselt number goes on reducing as suction is reduce, and it reduces still further as blowing is increase, and this is very much like what we had observed in case of force convection. So, the effect of suction is to enhance heat transfer and for reference, I have given for  $V_w$  star equal to 0 and prandtl equal to 0.7  $Nu_x Gr_x$  to the power of minus 4 is 0.353. So, you can see when  $V_w$  star is minus 1, it is 0.664, when it is minus 0.2 is 3 times, and when it is minus 3 it is almost 4 and a half times the nusselt number, so suction enhances a heat transfer and blowing reduces heat transfer.

(Refer Slide Time: 30:56)

**Curve-fit Correlations - L41(10/18)**

- For  $T_w = \text{const}$  and  $v_w = 0$ 

$$Nu_x = \frac{3}{4} \left[ \frac{2 Pr}{5(1 + 2(\sqrt{Pr} + Pr))} \right]^{0.25} (Gr_x Pr)^{0.25} \text{ (Ede)}$$

$$Nu_x = \left( \frac{Gr_x}{4} \right)^{0.25} \left[ \frac{0.676 \sqrt{Pr}}{(0.876 + Pr)^{0.25}} \right] \text{ (Ostrach)}$$
- For  $(T_w - T_\infty) = A x^{0.2}$  ( $q_w = \text{const}$ ) and  $v_w = 0$ 

$$Nu_x = \left[ \frac{Pr}{4 + 9\sqrt{Pr} + 10Pr} \right]^{0.2} (Gr_x^* Pr)^{0.2} \text{ (Fujii \& Fujii)}$$

$$Gr_x^* = Gr_x Nu_x = \frac{g \beta q_w x^4}{k \nu^2}$$

Now, for  $T_w$  equal to constant and  $V_w$  equal to 0, there are curve fit correlations have been obtained. So, for example, a correlation due to Ede is given here, the correlation due to Ede in Britten is given here that due to ostrich is given here. This ostrich solution is often found in under graduate text books, for  $T_w$  minus  $T_\infty$   $A X$  raise to 0.2 which implies constant wall heat flux and  $V_w$  equal to 0. Here is the correlation for the data by obtained by fujii and fujii, where  $Gr_x^*$  is now based on  $q_w x$  raise to 4  $k \nu$  square. So, these are simply for your reference that solutions presented on the previous slides can be correlated in terms of functions of prandtl number.

(Refer Slide Time: 32:05)

**Integral Solns  $T_w = \text{const}$ ,  $v_w = 0$  - L41( $\frac{11}{18}$ )**  
 Here integral eqns of slide 3 are evaluated by assuming

$$\frac{u}{U_{ref}} = \frac{y}{\delta} \left(1 - \frac{y}{\delta}\right)^2, \text{ and } \frac{T - T_\infty}{T_w - T_\infty} = \left(1 - \frac{y}{\delta}\right)^2$$

$$\frac{1}{105} \frac{d U_{ref}^2 \delta}{dx} = \frac{g \beta}{3} (T_w - T_\infty) \delta - \frac{\nu U_{ref}}{\delta} \text{ (Mom)}$$

$$\frac{1}{30} \frac{d U_{ref} \delta}{dx} = \frac{2 \alpha}{\delta} \text{ (Energy)}$$

Soln obtained assuming  $U_{ref} = C_1 x^m$  and  $\delta = C_2 x^n$  to give  $m = 0.5$  and  $n = 0.25$ . The result

$$\frac{\delta}{x} = 3.93 \left(\frac{0.952 + Pr}{Pr^2}\right)^{0.25} Gr_x^{-0.25} \rightarrow \delta \propto x^{0.25}$$

$$Nu_x = 0.508 \left(\frac{0.952 + Pr}{Pr^2}\right)^{-0.25} Gr_x^{0.25} \rightarrow h_x \propto x^{-0.25}$$

Now, we turned to integral solutions of the laminar boundary layer, and as you know integral solutions always require specification of a velocity and temperature profile. So, here I am going to defined a quantity called u ref, some reference velocity, I do not know what it is we will say, we shall find out in a moment what that is.

So, let us say, the velocity profile in the boundary layer will be u over U ref y over delta 1 minus y by delta whole square, you can see it satisfied the condition that u is equal to 0 at y equal to 0, as well as u equal to 0 at y equal to delta. So, it satisfy both conditions and it also satisfy the idea that the profile would **be would would** peak somewhere between 0 and delta. Likewise, T minus T infinity divided by T w minus T infinity is taken as 1 minus y by delta whole square.

(Refer Slide Time: 08:33)

### Governing Eqns - 2 L41( $\frac{3}{18}$ )

Thus, the modified momentum eqn and the energy eqn must be solved simultaneously along with the continuity eqn. Solutions can be obtained by similarity, integral or finite-difference methods. The Integral forms of Eqns can be derived as

$$\frac{d}{dx} \left( \int_0^\delta u^2 dy \right) = -\frac{\tau_w}{\rho} + g\beta \int_0^\delta (T - T_\infty) dy$$

$$\frac{d}{dx} \left\{ \int_0^\delta u (T - T_\infty) dy \right\} = \frac{q_w}{\rho c_p}$$

The BCs are: at  $y = 0$ ,  $u = 0$  and  $T = T_w$ . At  $y = \delta$ ,  $u = 0$  and  $T = T_\infty$ .

So, you substitute these temperature profiles and use our integral momentum equations which I have given; so, substitute for u here, T here as well as T here, and carry out the integrations.

(Refer Slide Time: 32:05)

### Integral Solns $T_w = \text{const}, v_w = 0$ - L41( $\frac{11}{18}$ )

Here integral eqns of slide 3 are evaluated by assuming

$$\frac{u}{U_{ref}} = \frac{y}{\delta} \left(1 - \frac{y}{\delta}\right)^2, \quad \text{and} \quad \frac{T - T_\infty}{T_w - T_\infty} = \left(1 - \frac{y}{\delta}\right)^2$$

$$\frac{1}{105} \frac{d U_{ref}^2 \delta}{dx} = \frac{g\beta}{3} (T_w - T_\infty) \delta - \frac{\nu U_{ref}}{\delta} \quad (\text{Mom})$$

$$\frac{1}{30} \frac{d U_{ref} \delta}{dx} = \frac{2\alpha}{\delta} \quad (\text{Energy})$$

Soln obtained assuming  $U_{ref} = C_1 x^m$  and  $\delta = C_2 x^n$  to give  $m = 0.5$  and  $n = 0.25$ . The result

$$\frac{\delta}{x} = 3.93 \left( \frac{0.952 + Pr}{Pr^2} \right)^{0.25} Gr_x^{-0.25} \rightarrow \delta \propto x^{0.25}$$

$$Nu_x = 0.508 \left( \frac{0.952 + Pr}{Pr^2} \right)^{-0.25} Gr_x^{0.25} \rightarrow h_x \propto x^{-0.25}$$

Then, you will see that the momentum equation transforms to 1 over 105 d U ref square delta divided by d x into g beta by 3 T w minus T infinity delta minus nu U ref by delta this will be the momentum equation, and 1 over 30 d U ref by delta d U ref delta by d x equal to 2 alpha by delta, where alpha is the thermal diffusivity. So, in order to obtained,

these two equations can be solved by assuming, let  $U_{ref} = C_1 x^m$ , and  $\delta = C_2 x^n$ . And if you substitute, then algebra will show that  $m = 0.5$  and  $n = 0.25$  satisfies these equation.

Now, again, this is about one, one and half page of algebra which I am not presenting here, but it is a fairly straightforward algebra to do, to give  $m = 0.5$  and  $n = 0.25$ . And therefore, you get the result, that the result is, once you substitute for  $U_{ref} = C_1 x^{0.5}$  and  $\delta = C_2 x^{0.25}$ . With these values you can show that  $\delta/x$  would be  $3.93 \text{ Gr}_x^{-0.25} \text{ Pr}^{-0.25}$ , and  $\delta$  would be proportional to  $x$  to the power of  $0.25$  -  $\delta$  increases with  $x$ .

$Nu_x$  is  $0.508 \text{ Gr}_x^{0.25} \text{ Pr}^{-0.25}$ , and therefore,  $h$  decreases with  $x$  - the local heat transfer coefficient decreases with  $x$ . These are important results, they agree fairly well, although they look very different from the forms of the curve fit correlations that I have given you in the previous page, but they agree fairly well with the correlations that I have shown you.

(Refer Slide Time: 35:30)

**Transition to Turbulence - L41( $\frac{12}{18}$ )**

- If we write the differential mom eqn for  $y = 0$  and  $y \geq \delta$  then,
 
$$U_{ref} \frac{dU_{ref}}{dx} = \frac{(\rho_\infty - \rho_w)g}{\rho} = g \beta (T_w - T_\infty)$$
 Hence,  $U_{ref} = \sqrt{g \beta (T_w - T_\infty) x}$  and  
 $Re_x = U_{ref} x / \nu = Gr_x^{1/2}$
- Generally, transition occurs at  $10^9 \leq Gr_{x,\delta} \leq 10^{10}$ . For gases and organic liquids,  $Gr_{x,\delta} \rightarrow 10^9$ . For  $Pr > 100$ ,  $Gr_{x,\delta} \rightarrow 10^{10}$ .
- In practical work, Rayleigh number  $Ra_{\delta} = Gr_{x,\delta} Pr = 10^9$  is taken as transition criterion.

April 01, 2011 14:28

Now, if we write the differential momentum equation, now we are looking at the idea of transitional to turbulence, before we move on to turbulent.

(Refer Slide Time: 05:40)

**Governing Eqns - 1 L41( $\frac{2}{18}$ )**  
 For constant properties, the governing eqns are

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

$$\rho \left[ u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right] = \frac{dp_{\infty}}{dx} + \mu \frac{\partial^2 u}{\partial y^2} - \rho g$$

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2}$$

where from hydrostatics,  $dp_{\infty}/dx = -\rho_{\infty} g$ . Now, using definition of volumetric coefficient of thermal expansion  $\beta$ , the vertical momentum eqn transforms to

$$\beta = -\frac{1}{\rho} \left( \frac{\rho - \rho_{\infty}}{T - T_{\infty}} \right)$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2} + g \beta (T - T_{\infty})$$

If we rewrite the momentum equation of the differential form, equation for y equal 0 and y greater than delta, that is, momentum equation that you see here. You write it for u equal to 0 and you write it for y equal to 0 and for y greater than delta, then in both cases convection terms will be absent, at y equal to 0  $dp_{\infty}/dx$  by  $dx$  when it replace by  $dw$  by  $dx$ , and this would be  $\rho_{\infty} - \rho g$ .

(Refer Slide Time: 35:30)

**Transition to Turbulence - L41( $\frac{12}{18}$ )**

- If we write the differential mom eqn for  $y = 0$  and  $y \geq \delta$  then,

$$U_{ref} \frac{dU_{ref}}{dx} = \frac{(\rho_{\infty} - \rho_w)g}{\rho} = g \beta (T_w - T_{\infty})$$

Hence,  $U_{ref} = \sqrt{g \beta (T_w - T_{\infty}) x}$  and  
 $Re_x = U_{ref} x / \nu = Gr_x^{1/2}$

- Generally, transition occurs at  $10^9 \leq Gr_{x,c} \leq 10^{10}$ . For gases and organic liquids,  $Gr_{x,c} \rightarrow 10^9$ . For  $Pr > 100$ ,  $Gr_{x,c} \rightarrow 10^{10}$ .
- In practical work, Rayleigh number  $Ra_x = Gr_x Pr = 10^9$  is taken as transition criterion.

So, you will get, then  $U_{ref} dU_{ref}/dx$  would be equal to  $\rho_{\infty} - \rho_w g$  and that would be equal to  $g \beta (T_w - T_{\infty})$ .

So,  $U_{ref}$  essentially is nothing but remember, this  $U_{ref}$  into  $d U_{ref}$  by  $d x$  will be  $d U_{ref}$  square by  $d x$  divided by  $1$  by  $2$ , and therefore, **u will be equal to**  $U_{ref}$  would be simply equal to under root of  $g \beta T_w \text{ minus } T_{\infty} x$  - there should be a factor  $2$  here inside the **root**.

And reynolds  $x$  would be equal to  $U_{ref} x$  divided by  $\nu$ , so correspondingly from this  $U_{ref}$  I can imagine a reynolds number, although it is not usually defined and that would equal grashof  $x$  to the power of half. So, essentially, if we say that the reynolds number of  $10$  raise to  $5$  or so, represents transitional then grashof number of  $10$  raise to  $10$  should roughly give you the transition criteria.

Now, generally, the transition occurs at  $10$  raise to  $9$  to  $10$  raise to  $10$  grashof numbers in that range. For gases and organic liquids, the lower range is found, and for prandtl number greater than  $1$  that is viscous fluids, the transition occurs little bit much later. So, in practical work, we define a rayleigh number **which is grashof** which is grashof into prandtl. And usually when rayleigh number assumes a value of  $10$  raise to  $9$ , we say transition has occurred, so this is taken as the transitional criterion.

(Refer Slide Time: 38:22)

**Turbulent BL - L41(<sup>13</sup>/<sub>18</sub>)**

Integral eqns are solved with

$$\frac{u}{U_{ref}} = \left(\frac{y}{\delta}\right)^{1/7} \left(1 - \frac{y}{\delta}\right)^4 \quad \text{and} \quad \frac{T - T_{\infty}}{T_w - T_{\infty}} = 1 - \left(\frac{y}{\delta}\right)^{1/7}$$

$$\tau_w = 0.0225 \rho U_{ref}^2 \left(\frac{U_{ref} \delta}{\nu}\right)^{-0.25}$$

$$St_x = \frac{q_w / (T_w - T_{\infty})}{\rho c_p U_{ref}} = 0.0225 \left(\frac{U_{ref} \delta}{\nu}\right)^{-0.25} Pr^{-2/3}$$

Soln obtained assuming  $U_{ref} = C_1 x^m$  and  $\delta = C_2 x^n$  to give  $m = 0.5$  and  $n = 0.7$ . The result

$$Nu_x = 0.0295 Pr^{7/15} \left(\frac{Gr_x}{1 + 0.494 Pr^{2/3}}\right)^{0.4} \rightarrow h_x \propto x^{+0.2}$$

This is unlike Laminar boundary layer.

April 21, 2011 18:28

To solve the temperature boundary layer then, again we need velocity profiles and this slide shows what the velocity profiles in turbulent boundary layer are  $u$  over  $U_{ref}$  equal to  $y$  by  $\delta$   $1$  raise to  $1$  by  $7$  into  $1$  minus  $y$  by  $\delta$  raise to  $4$  again  $u$  is equal to  $0$  at  $y$

equal to 0 and  $u$  is equal to 0 at  $y$  equal to  $\delta$  and  $T - T_\infty$  over  $T_w - T_\infty$  is equal to  $1 - y/\delta$  raised to the power of 1 by 7.

Now, of course, as usual in turbulent boundary layers, we cannot depend on these velocity profiles to give us the shear stress, because it will simply tend to infinity at  $y$  equal to 0. And therefore, we use this form which was also used in laminar boundary layers, force convection boundary layers  $0.0225 \rho U_{ref}^2$ , instead of  $u_\infty$  we are now replacing by  $U_{ref}$ ,  $U_{ref} \delta$  by  $\nu$  raised to the power of minus 0.25 and Stanton  $x$  likewise is  $0.0225 U_{ref} \delta$  by  $\nu$  minus 0.25 Prandtl raised to the power of minus 2 by 3.

So, both  $\tau_w$  and  $q_w$  which are required on the right hand side of the momentum and energy equations are represented in terms of  $\delta$ . So, if you make the if you assume now  $u$  equal to  $U_{ref}$  equal to  $C_1 x^m$  and  $\delta$  equal  $C_2 x^n$  and substitute in the integral momentum equations, then you find that the two equations are satisfied if  $m$  equal to 0.5 which was also the case of laminar boundary layer - laminar natural convection boundary layer. But  $n$  is now different,  $n$  is 0.7, instead of the value we had earlier  $n$  value was 0.25 in laminar boundary layer, but in turbulent boundary layer, we find that  $n$  should be about 0.7.

(Refer Slide Time: 32:05)

**Integral Solns  $T_w = \text{const}, v_w = 0$  - L41 ( $\frac{11}{18}$ )**  
 Here integral eqns of slide 3 are evaluated by assuming

$$\frac{u}{U_{ref}} = \frac{y}{\delta} \left(1 - \frac{y}{\delta}\right)^2, \quad \text{and} \quad \frac{T - T_\infty}{T_w - T_\infty} = \left(1 - \frac{y}{\delta}\right)^2$$

$$\frac{1}{105} \frac{d U_{ref}^2 \delta}{dx} = \frac{g \beta}{3} (T_w - T_\infty) \delta - \frac{\nu U_{ref}}{\delta} \quad (\text{Mom})$$

$$\frac{1}{30} \frac{d U_{ref} \delta}{dx} = \frac{2 \alpha}{\delta} \quad (\text{Energy})$$

Soln obtained assuming  $U_{ref} = C_1 x^m$  and  $\delta = C_2 x^n$  to give  $m = 0.5$  and  $n = 0.25$ . The result

$$\frac{\delta}{x} = 3.93 \left(\frac{0.952 + Pr}{Pr^2}\right)^{0.25} Gr_x^{-0.25} \rightarrow \delta \propto x^{0.25}$$

$$Nu_x = 0.508 \left(\frac{0.952 + Pr}{Pr^2}\right)^{-0.25} Gr_x^{0.25} \rightarrow h_x \propto x^{-0.25}$$

(Refer Slide Time: 38:22)

**Turbulent BL - L41**  $\left(\frac{13}{18}\right)$

Integral eqns are solved with

$$\frac{u}{U_{ref}} = \left(\frac{y}{\delta}\right)^{1/7} \left(1 - \frac{y}{\delta}\right)^4 \quad \text{and} \quad \frac{T - T_{\infty}}{T_w - T_{\infty}} = 1 - \left(\frac{y}{\delta}\right)^{1/7}$$
$$\tau_w = 0.0225 \rho U_{ref}^2 \left(\frac{U_{ref} \delta}{\nu}\right)^{-0.25}$$
$$St_x = \frac{q_w / (T_w - T_{\infty})}{\rho c_p U_{ref}} = 0.0225 \left(\frac{U_{ref} \delta}{\nu}\right)^{-0.25} Pr^{-2/3}$$

Soln obtained assuming  $U_{ref} = C_1 x^m$  and  $\delta = C_2 x^n$  to give  $m = 0.5$  and  $n = 0.7$ . The result

$$Nu_x = 0.0295 Pr^{7/15} \left(\frac{Gr_x}{1 + 0.494 Pr^{2/3}}\right)^{0.4} \rightarrow h_x \propto x^{+0.2}$$

This is unlike Laminar boundary layer.

April 21, 2011 19:28

And with these two choices, the equations momentum and energy equations are satisfied, and as a result if you follow the same algebra that we did for laminar boundary layer, we find that in turbulent boundary layers the Nusselt number is 0.0295 Prandtl raised to 7 by 15 into Grashof number divided by 1 plus 0.494 Prandtl raised to 2 by 3 raised to 4.

Now, in this case  $h_x$ , this is  $h$  into  $x$  divided by  $k$ , so  $h_x$  here turns out to be proportional to  $x$  raised to plus 0.2. In other words, in turbulent boundary layer the **heat transfer** local heat transfer coefficient increases with  $x$ , whereas in laminar boundary layer the heat transfer coefficient was decreasing with  $x$ . Now, this is a very special feature of turbulent boundary layers - natural convection turbulent boundary layer - that the local heat transfer coefficient actually increases with  $x$  as shown here, so we note this difference and that is of considerable importance.

(Refer Slide Time: 41:36)

**Overall Correlation - L41( $\frac{14}{18}$ )**  
For the entire range of Rayleigh Numbers and for  $T_w = \text{const}$  and  $v_w = 0$ , the currently accepted correlation<sup>1</sup> is

$$\overline{Nu}_L = 0.68 + \frac{0.67 Ra_L^{0.25}}{[1 + (0.492/Pr)^{9/16}]^{4/9}} \quad 10^{-1} < Ra_L < 10^9$$
$$\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/4}}{[1 + (0.492/Pr)^{9/16}]^{4/9}} \right\}^2 \quad 10^9 < Ra_L < 10^{12}$$

where  $\overline{h}_L = \frac{1}{L} \int_0^L h_x dx$  and  $\overline{Nu}_L = \overline{h}_L L/k$ .

Correlations for natural convection from other geometries such as inclined/horizontal plates, cylinders, cavities etc ( see, Incropera F P and Dewitt D P, Fundamentals of Heat and Mass Transfer, 4th Edition, John Wiley and Sons, New York, 1996 )

<sup>1</sup>Churchill and Chu, JHMT, vol 18, p 1323, ( 1975 )

(Refer Slide Time: 41:55)

Now, for the entire range of rayleigh numbers and for  $T_w$  constant and  $V_w$  equal to 0, the currently accepted correlations is like this. So, over all correlations, these are the integral value, that is,  $Nu_L$  is actually  $h_L$  into  $L$  by  $k$  and  $h_{bar} L$  is  $1$  over  $L$  integral  $h_x dx$  from  $0$  to  $L$ , where  $L$  is the length of the plate.

(Refer Slide Time: 41:36)

**Overall Correlation - L41( $\frac{14}{18}$ )**  
For the entire range of Rayleigh Numbers and for  $T_w = \text{const}$  and  $v_w = 0$ , the currently accepted correlation<sup>1</sup> is

$$\overline{Nu}_L = 0.68 + \frac{0.67 Ra_L^{0.25}}{[1 + (0.492/Pr)^{9/16}]^{4/9}} \quad 10^{-1} < Ra_L < 10^9$$
$$\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/4}}{[1 + (0.492/Pr)^{9/16}]^{8/27}} \right\}^2 \quad 10^9 < Ra_L < 10^{12}$$

where  $\bar{h}_L = \frac{1}{L} \int_0^L h_x dx$  and  $\overline{Nu}_L = \bar{h}_L L/k$ .

Correlations for natural convection from other geometries such as inclined/horizontal plates, cylinders, cavities etc ( see, Incropera F P and Dewitt D P, Fundamentals of Heat and Mass Transfer, 4th Edition, John Wiley and Sons, New York, 1996 )

<sup>1</sup>Churchill and Chu, JHMT, vol 18, p 1323, ( 1975 )

So, the currently accepted correlations are  $\overline{Nu}_L$  equal to 0.68 rayleigh number based on L, and rayleigh number as you know is the product of grashof number and prandtl number. And then, these are the correlations given by churchill and chu international journal of heat and mass transfer 1975. For the lower range of reynolds number, this would be the laminar range, as we said, transition occurs at around  $10^9$ , and this would be, if the turbulent range obtained, that is, if the plate grashof number was  $10^9$  and above then, we would use that correlation.

So, correlations for natural convection from other geometries such as inclined or horizontal plates, cylinders, cavities, etcetera, are readily available and you might have already used - I mean - in your undergraduate work. I am giving here one reference Incropera and Dewitt, Fundamentals of Heat and Mass transfer John Wiley in 1996, which gives a number of correlations for natural convection in different situations.

(Refer Slide Time: 43:23)

**Simultaneous HMT - L41(<sup>15</sup>/<sub>18</sub>)**

We consider inert mass transfer with heat transfer at **small mass transfer rates and assume constant properties**. Then for  $\Delta T = T_w - T_\infty = A x^n$  and  $\Delta \omega_y = \omega_{y,w} - \omega_{y,\infty} = A x^n$ , it can be shown that

$$f'' + (n+3) f f' - (2n+2) f'^2 + \theta + F_1 \Phi = 0$$

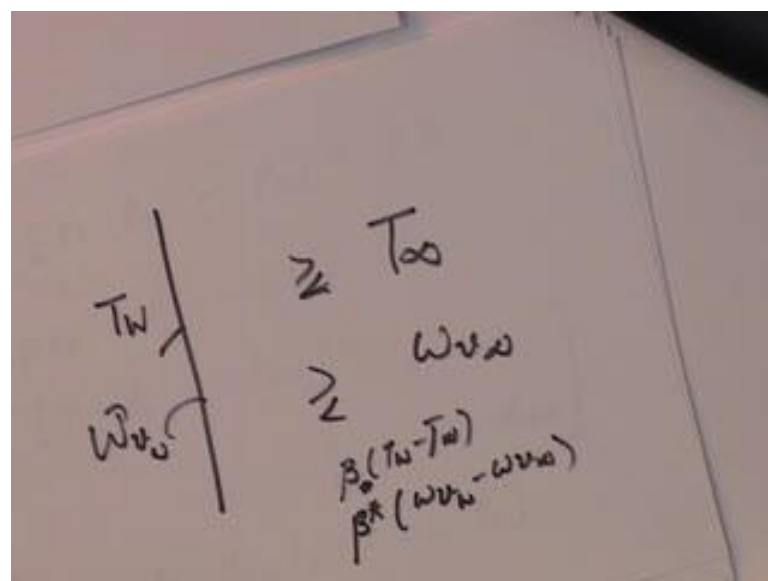

$$\theta'' + Pr \{ (n+3) f \theta' - 4 n f' \theta \} = 0$$

$$\Phi'' + Sc \{ (n+3) f \Phi' - 4 n f' \Phi \} = 0$$

and, as before  $\eta = \frac{y}{x} \left( \frac{Gr_{x,\Delta T}}{4} \right)^{1/4}$

where  $\Phi = (\omega_y - \omega_{y,\infty}) / \Delta \omega_y$  and  $F_1 = (\beta^* \Delta \omega_y) / (\beta \Delta T)$ .  
 The BCs are  $f(0) = f'(0) = 0$ ,  $\theta(0) = \Phi(0) = 1$  and  $f(\infty) = \theta(\infty) = \Phi(\infty) = 0$ . Notice from slide 9 that as  $v_w \rightarrow 0$ ,  $f(0) = 0$ .

(Refer Slide Time: 43:38)

Now, we turn to the case of simultaneous heat and mass transfer, there is, we are assuming that  $T_w$ , say, this is  $T_w$  and there is  $\omega_{v,w}$  is greater than or less than  $\omega_{v,\infty}$  and  $T_w$  is greater than or less than  $T_\infty$ . So, main driving forces are a  $\beta$  times  $T_w$  minus  $T_\infty$ , which I will call  $\beta t$  if you like, or simply  $\beta t$  which is thermal cubical expansion, but we can also define  $\beta^*$  for mass transfer into  $\omega_{v,w}$  minus  $\omega_{v,\infty}$ , so the definition of  $\beta$  and  $\beta^*$  is very, very, parallel to each other.

(Refer Slide Time: 43:23)

**Simultaneous HMT - L41** <sup>(15)</sup>/<sub>(18)</sub>

We consider inert mass transfer with heat transfer at **small mass transfer rates and assume constant properties**. Then for  $\Delta T = T_w - T_\infty = A x^n$  and  $\Delta \omega_v = \omega_{v,w} - \omega_{v,\infty} = A x^n$ , it can be shown that

$$f''' + (n+3) f f'' - (2n+2) f'^2 + \theta + F_\beta \Phi = 0$$

$$\theta'' + Pr \left\{ (n+3) f \theta' - 4 n f' \theta \right\} = 0$$

$$\Phi'' + Sc \left\{ (n+3) f \Phi' - 4 n f' \Phi \right\} = 0$$

and, as before  $\eta = \frac{y}{x} \left( \frac{Gr_{x,\Delta T}}{4} \right)^{1/4}$

where  $\Phi = (\omega_v - \omega_{v,\infty}) / \Delta \omega_v$  and  $F_\beta = (\beta^* \Delta \omega_v) / (\beta \Delta T)$ .  
 The BCs are  $f(0) = f'(0) = 0$ ,  $\theta(0) = \Phi(0) = 1$  and  $f(\infty) = \theta(\infty) = \Phi(\infty) = 0$ . Notice from slide 9 that as  $v_w \rightarrow 0$ ,  $f(0) = 0$ .

So, again, we can show that similarity solutions are possible, if  $T_w - T_\infty$  varies as  $A X^n$  and also  $\Delta \omega_v$  which is  $\omega_{v,w} - \omega_{v,\infty}$  in equal to  $A X^n$  both should vary as  $x$  to the power of  $n$ . Then, similarity solutions are possible and you get the momentum equation as  $f''' + (n+3) f f'' - (2n+2) f'^2 + \theta + F_\beta \Phi = 0$ , there the buoyancy also due to the concentration difference.

And the energy equation would read like that, and the species transfer the  $\omega_v$  equation would read in this fashion. I have define  $\phi$  as  $\omega_v - \omega_{v,\infty}$  divided by  $\Delta \omega_v$   $f_\beta$  is simply the ratio of the buoyancies due to concentration and temperature differences. The boundary conditions would be  $f(0) = f'(0) = 0$ ,  $\theta(0) = \phi(0) = 1$  and  $f(\infty) = \theta(\infty) = \phi(\infty) = 0$ .

Now, notice from slide 9 that as  $v_w$  tends to 0  $f(0)$  tends to 0, so we are assuming at the moment that we are dealing with a very small mass transfer right from. Now  $\eta$  would be still taken **in the as** as defined as  $Gr_x$  based on temperature difference rather than based on mass transfer difference - i mean - mass fraction difference.

(Refer Slide Time: 46:20)

**Solutions for (  $n = 0, Pr = 0.7, F_\beta = 1$  )**  
**- L41( $\frac{16}{18}$ )**  
 *$F_\beta = 1$  implies aiding buoyancies.*

1.0	0.410	0.490	1.111	0.97	0.7
5.0	0.379	0.917	0.985	0.329	0.14
10.0	0.371	1.176	0.937	0.233	0.07

So, these are the set of equations, again, we can solve them by finite difference method and here is the solutions. So, I am taking the case of constant wall temperature, the prandtl number is taken as 0.7 and f beta is equal to 1, now f beta equal to 1 implies that we have aiding that there is the concentration buoyancy and the thermal buoyancy are aiding each other.

And in which case the nusselt number would get defined in this fashion and sherwood number which is the dimensionless mass transfer coefficient, would get defined in this fashion. And this is the case of limiting very, very, small mass transfer at the wall. Then, **you will get** for different values of S c you get 0.5, 0.7, 1, 5, 10, I have calculate minus theta 0 minus phi dash 0, so you can get nusselt numbers out of this, you get sherwood numbers out of this.

And notice that I have also printed out here, the boundary layer thickness of concentration and boundary layer thickness of temperature. So, when schmidt number is **close to** equal to prandtl number, the ratio is 1; when schmidt number is lower than prandtl number, then the ratio is 1.01 very very close, but the lewis number now is 1.4. And then, when schmidt number exceeds prandtl number then, you find that the concentration boundary layer thickness is smaller than the temperature boundary layer thickness. Now this is to be expected, but it is good to notice it from the results as well.

**Solutions for (  $n = 0, Pr = 0.7, F_\beta = -0.5$  )**  
**-  $L41(\frac{17}{18})$**

$F_\beta = -0.5$  implies opposing buoyancies

Sc	$-\theta'(0)$	$-\phi'(0)$	$f'(0)$	$\frac{\delta}{\delta_T}$	Le = Pr / Sc
0.5	0.278	0.231	0.383	1.004	1.4
0.7	0.297	0.297	0.404	1.00	1.0
1.0	0.309	0.367	0.425	0.984	0.7
5.0	0.337	0.776	0.507	0.350	0.14
10.0	0.342	1.027	0.536	0.256	0.07

Compared to  $F_\beta = 1, f'(0), Nu$  and  $Sh$  have now reduced .  
For other problems, see ( Y. Jaluria Natural Convection Heat and Mass Transfer, Pergamon Press, NY, 1980 )

Similarly, the results for  $f_\beta$  equal to minus 0.5, now you find that whereas, the thermal buoyancy is trying to take the fluid up, mass transfer buoyancy is trying to take it down. So, you have opposing effects due to opposing buoyancies. And you can see that compare to  $f_\beta$  equal to 1 with the aiding buoyancies, you find the nusselt number and sherwood numbers are all smaller irrespective of the schmidt number that you use.

Now, there are many other variations of, now in all this cases, I have use simply constant wall temperature, but there are variety of cases of finite  $n$  and so on so forth, which have been handle in a very specialize book by Y Jaluria and it is called Natural Convection Heat and Mass transfer, Pergamon Press and published in 1980, you can refer to that. But the important thing is, **when aiding** compare to aiding situation, the opposing situation lowers the nusselt number as well as the sherwood number.

**Large Mass Transfer Rates - L41(18)**  
 At large mass transfer rates, it can be shown that

$$f(0) = \frac{-v_w}{\nu G} = \frac{-\Phi'(0)}{Sc(n+3)} \times B_m = \frac{-\theta'(0)}{Pr(n+3)} \times B_m$$

Solutions for  $n = 0$ ,  $Pr = Sc = 0.7$  and  $F_\beta = 1$ .

$B_m$	$Sh_x (Gr_{x,\Delta T}/4)^{-0.25}$	$f'(0)$	$Sh/Str$	$\frac{\ln(1+B_m)}{B_m}$
0.0	0.421	1.142	1.0	1.0
0.1	0.400	1.135	0.951	0.953
0.2	0.381	1.128	0.907	0.912
0.3	0.364	1.121	0.866	0.875
0.4	0.350	1.114	0.833	0.841
0.5	0.336	1.107	0.800	0.811

The data show that  $Sh/Str \approx \ln(1+B_m)/B_m$ . So, for const properties, Reynolds flow model is verified.

Finally, those solutions were obtained at low vanishing mass transferring. Now, suppose, we take  $f(0)$  equal to  $-\frac{v_w}{\nu G}$ , then that will become  $-\frac{\Phi'(0)}{Sc(n+3)} \times B_m$  and  $-\frac{\theta'(0)}{Pr(n+3)} \times B_m$ . So, if I use this as the boundary conditions for the momentum equation, I can now deal with large mass transfer rates also and for  $n$  equal to 0 which is constant wall temperature and I have taken deliberately the case of  $Pr$  and  $Sc$  equal and  $F_\beta$  equal to 1 that is aiding buoyancies. Then, you find that for different values of  $B_m$  from 0 to 0.5, the Sherwood number goes from 0.421, 0.4, 0.381, 0.364, 0.35, so as  $B_m$  increases the Sherwood number goes on decreasing.

But if I calculate  $\frac{Sh}{Sh^*}$  that is Sherwood number or any  $B_m$  divided by Sherwood number for  $B_m$  equal to 0, then I get 1.951 and so on so forth. Now, if I also calculate  $\frac{\ln(1+B_m)}{B_m}$ , then I get those values and you can see those are very, very, close to the  $\frac{Sh}{Sh^*}$  which have obtained from exact solution to the boundary layer equation. And therefore, these data show that  $\frac{Sh}{Sh^*} \approx \frac{\ln(1+B_m)}{B_m}$  is also verified in natural convection boundary layers as long as properties are constant.

And this was the result we use extensively in forced convection in Reynolds flow modeling, but it is also applicable to the case of natural convection boundary layers and

other property corrections can also be applied in the same way that we had applied in reynolds flow model.

So with this, I conclude the lecture on Natural Convection Heat and Mass Transfer.
