Similarity Solution to Velocity BL

(Refer Slide Time: 00:34)

In the last lecture, we converted the partial differential equation of a two dimensional boundary layer to an ordinary differential equation which we call the similarity equation. The purpose of this lecture is to show how to solve such a similarity equation by shooting method.

(Refer Slide Time: 00:48)

Similarity Eqn and BCs -L7($\frac{1}{14}$)

Our interest is to solve

$$f''' + \left(\frac{m+1}{2}\right) f f' + m(1-f^2) = 0 \quad (1)$$
$$f(0) = -B_f \left(\frac{2}{m+1}\right) \quad f'(0) = 0 \quad \text{and} \quad f'(\infty) = 1 \quad (2)$$

The solution gives the velocity profiles

$$f'(\eta) = \frac{u}{U_\infty} = F(m, B_f) \quad (3)$$
$$\frac{v}{U_\infty} Re_x^{0.5} = -\left(\frac{m+1}{2}\right) \left\{ f + \left(\frac{m-1}{m+1}\right) \eta f' \right\} \quad (4)$$

0 March 21, 2015 1 / 14

In this lecture, I will also present some solutions to the velocity boundary layer equation. Our interest is to solve this third order ordinary differential equation with the boundary condition $f(0)$ equal to B_f which we defined as the blowing parameter into $2m + 1$. $f'(0)$ is equal to 0 which is the no slip condition and $f'(\infty) = 1$ is the boundary condition. So, our solution is for the velocity profile, $f'(\eta) = \frac{u}{U_\infty}$ will be function firstly of the pressure gradient parameter because U_∞ is a function of m and B_f which arises from the manner in which V_w , the wall velocity varies.

(Refer Slide Time: 02:01)

$$\eta = y \sqrt{\frac{U_{\infty}}{\nu x}}$$

$$U_{\infty} = c x^m$$

$$\eta = y \sqrt{\left[\frac{c}{\nu} \cdot x^{\frac{m-1}{2}} \right]}$$

$$\frac{dp_{\infty}}{dx} = -\rho U_{\infty} \frac{dU_{\infty}}{dx}$$

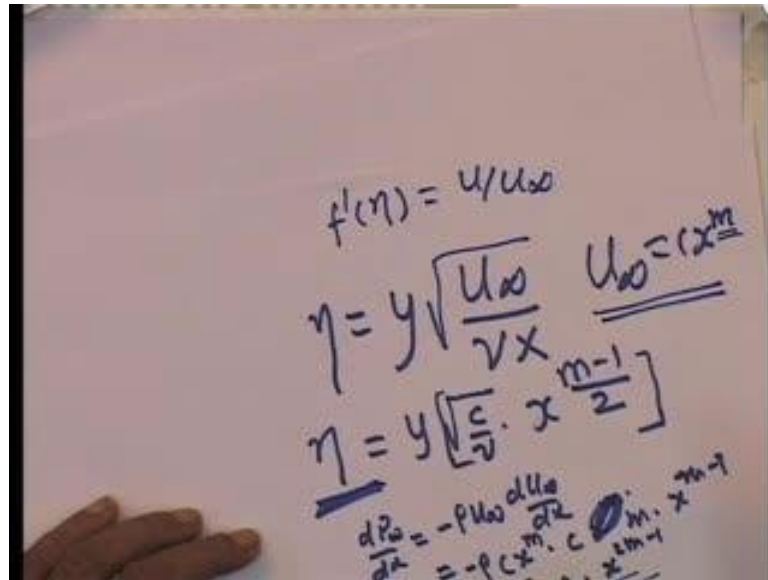

$$= -\rho c x^m \cdot c$$

$$= -\rho c^2 m \cdot x^{m-1}$$

Secondly, our velocity distribution in the y direction would be given by that. So, once we solve this equation, we get f' variations from which we get the velocity distribution v as well as u as a function of y . Just by way of reminder, I may say η , the similarity variable η is nothing but y times under root U_{∞} divided by νX , where U_{∞} is $c x$ raised to m and therefore, you will see this becomes nothing but c by νx raised to $m - 1$ by 2 . That is what the variable η is. This is the stretching parameter.

Similarity solutions are possible only when U_{∞} varies in this fashion. We say m is a pressure gradient parameter; why - because remember dp_{∞} by dx is simply minus $\rho U_{\infty} dU_{\infty}$ by dx .

(Refer Slide Time: 02:01)

That is equal to minus rho c x raised to m c into m into x raised to m minus 1 or that is equal to minus rho c square m into x raised to 2 m minus 1. So, you will see the pressure gradient is totally determined by whether m is positive or negative and therefore, we call this m as a pressure gradient parameter. This is called the similarity independent variable and f dash eta is equal to u over U infinity.

(Refer Slide Time: 03:55)

Parameters of Interest - L7($\frac{2}{14}$)

The $f'(\eta)$ solution gives the Coefficient of Friction $C_{f,x}$ as a function of Reynolds number $Re_x = U_\infty x / \nu$

$$\tau_{w,x} = \mu \left\{ \frac{\partial u}{\partial y} \right\}_{y=0} = \mu U_\infty \sqrt{\frac{U_\infty}{\nu x}} f''(0) \quad (5)$$

$$C_{f,x} = \frac{\tau_{w,x}}{\rho U_\infty^2 / 2} = 2 f''(0) Re_x^{-0.5} \quad (6)$$

$$\bar{C}_f = \frac{1}{L} \int_0^L \tau_{w,x} dx = \left(\frac{2}{3m+1} \right) C_{f,x} \quad (7)$$

Therefore, we must determine $f''(0)$. Further parameters of interest will be listed in a later slide.

Now we want to solve this third order equation - third order ordinary differential equation. We essentially split it up into 3 first order differential equations as shown.

Before I do that, let me just tell you the f' solution gives the Coefficient of Friction as a function of the Reynolds number.

(Refer Slide Time: 04:13)

$$\tau_w = \mu \left. \frac{du}{dy} \right|_{y=0}$$

$$= \mu U_\infty \left. \frac{df}{d\eta} \right|_{\eta=0}$$

$$= \mu U_\infty \sqrt{\frac{U_\infty}{\nu x}} \cdot f''(0)$$

$$C_{fx} = \frac{\tau_w}{\rho U_\infty^2 / 2} = \frac{2 f''(0) \cdot \text{Re}_x^{-0.5}}{1}$$

So, the shear stress at the wall would be μ times du by dy which is equal to 0. So, τ_w will be μ times du by dy at y equal to 0 which I can also write- μ times U_∞ df by $d\eta$ at η equal to 0.

I can also write it as $\mu U_\infty \left. \frac{df}{d\eta} \right|_{\eta=0}$ which I shall write as $\mu U_\infty \left. \frac{df}{d\eta} \right|_{\eta=0}$. As you know, since η is equal to $y \sqrt{U_\infty / \nu x}$, you will see this difference becomes μ times U_∞ under root U_∞ by νx , which is $d\eta$ by dy into $f''(0)$.

We define C_{fx} as the shear stress divided by the kinetic energy of the free stream and therefore, this will become 2 times $f''(0)$ into Reynolds x to the power of minus 0.5 .

That is what I have shown here; the local skin friction coefficient would be defined as that. So, once we have solved the problem, we can determine $f''(0)$. Sometimes it is also of interest to find out average skin friction coefficient over a length L . Well, all you do is integrate τ_w all x from 0 to L and divide by the length L and you will get that. Therefore, we must determine $f''(0)$ for which we have no

boundary condition at the moment. Further parameter of interest will be listed in a later slide.

(Refer Slide Time: 06:21)

Shooting Method - L7($\frac{3}{14}$)
 The 3rd order equation is split into three 1st order ODEs

$$\frac{df}{d\eta} = f' \quad \text{with} \quad f(0) = B_f \left(\frac{2}{m+1} \right) \quad (\text{known}) \quad (8)$$

$$\frac{df'}{d\eta} = f'' \quad \text{with} \quad f'(0) = 0 \quad (\text{known}) \quad (9)$$

$$\frac{df''}{d\eta} = f''' = - \left[\left(\frac{m+1}{2} \right) f f'' + m (1 - f^2) \right] \quad (10)$$

with $f''(0)$ (unknown)

Each equation is solved by Runge-Kutta Method from $\eta = 0$ to $\eta = \eta_{\max}$ (in lieu of $\eta = \infty$).
 Typically, $3 < \eta_{\max} < 10$ suffices depending on the value of B_f and m .

As I said, we split up the third order equation into three first order equations. The first is $\frac{df}{d\eta} = f'$ and I can solve it from $\eta = 0$ to $\eta = \infty$, because I know the boundary condition $f(0) = \frac{2B_f}{m+1}$ - this is known because I have already specified the value of B_f and I have already specified the value of m . $\frac{df'}{d\eta} = f''$ will be equal to f'' ; this is a second ordinary differential equation with $f'(0) = 0$ because this is a known condition. Similarly, $\frac{df''}{d\eta} = f'''$ will be f''' and f''' will be simply $- \left[\left(\frac{m+1}{2} \right) f f'' + m (1 - f^2) \right]$ from our ordinary differential equation, it will be this quantity with a negative sign and that is what I have written here. But to solve this equation, I do not know the initial condition, $f''(0)$ and that is an unknown condition.

How do I do that? I will show that later. Since these three equations are ordinary differential equations, I can always solve them by Runge-Kutta method with which you are already familiar. From $\eta = 0$ to $\eta = \eta_{\max}$ - I say η_{\max} in lieu of infinity, because it is no point in going on solving for a length longer than is necessary. Usually values of η_{\max} of the order of 3 to 10 will suffice depending on the value B_f and m .

(Refer Slide Time: 08:31)

Iterative Algorithm - L6($\frac{4}{14}$)

- 1 Select values of m and B_f
- 2 Select η_{max} and step change $d\eta$
- 3 Guess $f'(0)$
- 4 Solve **three equations simultaneously** by R-K method
- 5 Check if value of $f'(\eta_{max}) = 1$ or NOT
- 6 If NOT, revise $f'(0) = \Phi$ as

$$\Phi(k+1) = \Phi(k) + (1 - \psi(k)) \left[\frac{\Phi(k) - \Phi(k-1)}{\psi(k) - \psi(k-1)} \right]$$

where k is iteration number and $\psi = f'(\eta_{max})$.

- 4 Go to step 4
- 5 At Convergence,
 - 1 Print values of $f(\eta)$, $f'(\eta)$, $f''(\eta)$.
 - 2 Note value of $f'(0)$

March 21, 2010 4:14

So, eta max is a fictitious quantity; it represents infinity condition because in a numerical calculation you must give some value to infinity and that is given as eta max. What would be the solution algorithm?

(Refer Slide Time: 08:51)

Select the value of m and B_f which is given. You want to solve this problem for a given pressure gradient and given blowing parameter. Select eta max and step change $d\eta$. You are solving from eta equal to 0 to eta equal to eta max; the conditions known here are $f(0) = f'(0)$.

But $f''(0)$ is not known; $f''(0)$ is not known. This η equal to 0 to η_{max} is divided into very small number of steps; we call them $d\eta$. Each step is called $d\eta$ and we intend to obtain solution at different values of η along up to here. Solve three equations simultaneously by Runge-Kutta method by first guessing a value of $f''(0)$. Now, if I choose a value which is not correct then what do I expect? I expect $f'(\eta_{max})$ to somehow go to 1 at correct value of $f''(0)$.

But what I will find if my guess is not quite correct? I will end up like this. Obviously, I must refine my guess for $f''(0)$ and in the next guess I may find that I come out in that position. So, this is guess 1, this is guess 2 - neither is $f'(\eta_{max})$ is not equal to 1.

So, I check if $f'(\eta_{max})$ is equal to 1. Since it is not, I must refine these two first two guesses and I go on doing that by this little formula. It is simply a linear interpolation of the errors on the both sides so that the third guess will give me an error in $f''(0)$ which is more and more accurate. If I say $f''(0)$ by ϕ , then ϕ at k plus first iteration would be equal to $\phi_{k+1} = \frac{\psi_k \phi_{k-1} - \phi_k \psi_{k-1}}{\psi_k - \psi_{k-1}}$, where k is the iteration number and ψ is the value of $f'(\eta_{max})$ predicted at η_{max} .

So, I sense which way to move for $f''(0)$ by observing the value of $f'(\eta_{max})$ η equal to η_{max} . If of course, I now find that $f'(\eta_{max})$ is equal to 1 then I say assumed value of $f''(0)$ is a correct one at convergence then print values of $f(\eta)$, $f'(\eta)$ and $f''(\eta)$ and note down the value of $f''(0)$ which is required for calculation of the skin friction coefficient.

(Refer Slide Time: 12:05)

Typical Convergence History - $L7(\frac{5}{14})$

Solution is obtained for $m = 0$, $B_f = 0$, $\eta_{max} = 7$ and $d\eta = \eta_{max}/300$. Initial Guess, $f''(0) = 0.02$.

k	$f''(0)$	$f(\eta_{max})$	$f'(\eta_{max})$	$f''(\eta_{max})$
1	0.02	0.465E+00	0.123E+00	0.115E-01
2	0.07	0.147E+01	0.342E+00	0.111E-01
3	0.220	0.382E+01	0.761E+00	0.125E-02
4	0.306	0.496E+01	0.948E+00	0.321E-03
5	0.329	0.525E+01	0.997E+00	0.221E-03
6	0.33071	0.527E+01	0.100E+01	0.216E-03

Because of very poor guess, 6 iterations are required. In this case, $C_{f,x} = 0.6614 Re_x^{-0.5}$ and $\bar{C}_f = 1.28 Re_x^{-0.5}$.
Series Solution: $C_{f,x} = 0.664 Re_x^{-0.5}$ and $\bar{C}_f = 1.328 Re_x^{-0.5}$.

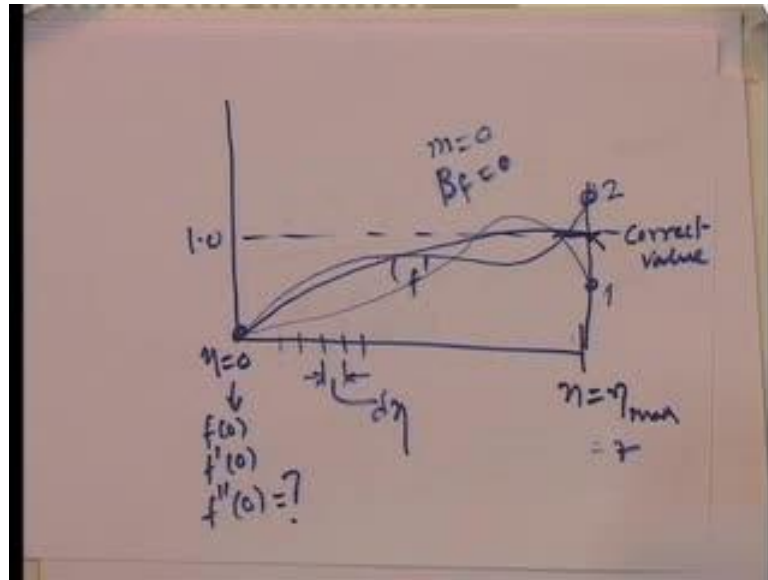

(Refer Slide Time: 12:20)

$$f''' + \frac{1}{2} f f'' = 0 \quad m=0$$

$$\begin{aligned} f'(0) &= 0 & f(0) &= \frac{B f^2}{m+1} = 0 \\ f'(\infty) &= 1 \end{aligned}$$

Here, I show a typical calculation for a set of assuming m is equal to 0 and B_f is equal to 0- the equation that I am really solving is simply f triple prime since m is equal to 0 $m f f$ double prime equal to 0, this is the equation I am solving for m equal to 0 and the boundary condition is that f dash 0 is equal to 0, f dash infinity is equal to 1, and f 0 which is equal to B_f into 2 by m plus 1 since this is 0 and B_f is equal to 0, f 0 is also equal to 0.

(Refer Slide Time: 13:10)

I have taken in this case after some experience that eta max should be about 7. I took eta equal to 7 because I am solving for m equal to 0 and B f equal to 0 which is essentially a flood pit boundary layer without suction or blowing and I have divided this into 300 steps. I am not suggesting that 300 is really required; you can get away with smaller number but just I took a value of 300. I have d eta is 1 divided by 300 of eta max.

Since I do not know the solution (Refer Slide Time: 13:46) I made an initial guess of f double prime equal to 0.02. This was my first guess and I found eta max f dash eta max equal to 0.123; obviously this is not correct. I then refined the guess to 0.07 and I found that it is 0.342 with these two solutions (Refer Slide Time: 14:09) I let our iteration refinement formula to take over and then I find that the third guess was 0.22 and it became 0.761, fourth guess 0.306 948, fifth 0.329 0.997 and 6 gave me 0.33071 and f dash max is indeed 1, which means that this value of f double prime 0 is correct.

When you are solving this for the first time obviously you do not know f double prime 0. You do not know what eta max to take? So, the best thing is to increase the value of eta max, decrease the value of eta max and in each case determine the value of f double prime 0 corresponding to f dash max equal to 1, so that our solution should be independent of the number of points taken in the domain and the eth value of eta max chosen.

Of course, you do not want η_{max} to be too large at the same time it should not be so small that you do not resolve the entire viscosity affected region properly. Because I started with a very poor guess of 0.02, I needed 6 iterations to discover the correct value of $f''(0)$. In this case therefore, $C_f x$ which is $2 f''(0) Re x$ to the half will be simply 2 times 0.33, so that is equal to 0.6614, $C_f \bar{x}$ will be 1.28. It is also possible that the equation that I wrote here- there is a series solution possible for this equation and that series solution gives $C_f x$ equal to 0.664 and $C_f \bar{x}$ equal to 1.328.

(Refer Slide Time: 16:13)

We are very close. Our shooting method has given very close answer to the series solution. Now, you can see how the profiles look like for the flood pit boundary layer without suction and blowing. You will see the value of f' goes from 0 to 1 very asymptotically and that is u/U_{∞} .

Where f' becomes constant- f becomes linear and the value of f'' , you can see 0.33 and when you go towards the η , you will see that the second derivative of f or the du/dy is also going to 0 which is what we expect. So that also is correct. Actually u/U_{∞} becomes very close to 1 at about η equal to ϕ .

So, we took η_{max} equal to 7; well that is good enough even if I took η_{max} equal to 6, I would get exactly the same results. Normally one does not want this to be too large,

the difference between edge of the boundary layer and the eta max chosen should not be too large because unnecessarily you are doing computations which need not be done.

(Refer Slide Time: 17:24)

Characteristic Thicknesses - L7($\frac{7}{14}$)

- 1 The *Physical Thickness* δ is notionally associated with value of y where $u/U_\infty = f'(\eta) \approx 0.99$.
- 2 *Displacement Thickness* δ_1 is defined as

$$\delta_1 = \int_0^\infty \left(1 - \frac{\rho u}{\rho_\infty U_\infty}\right) dy \quad (11)$$

It represents the **Mass Deficit** caused by the viscosity affected low velocity (that is $u < U_\infty$) region near a wall.

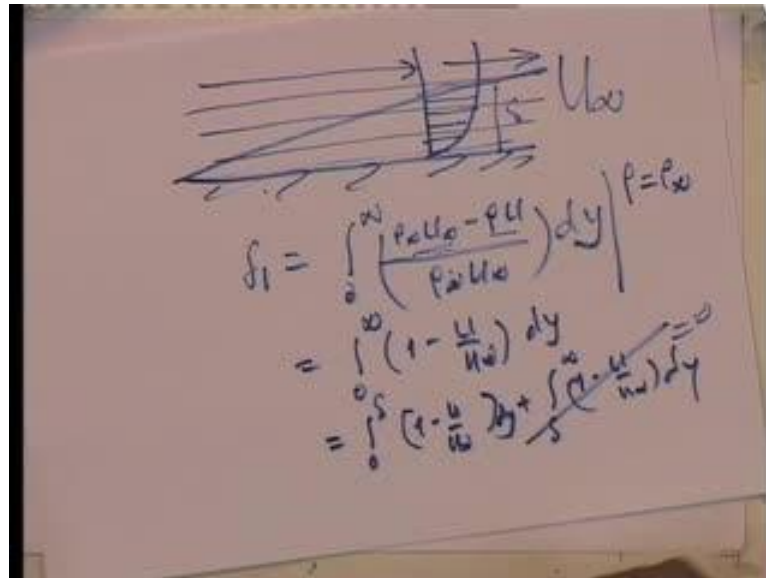

- 3 *Momentum Thickness* δ_2 is defined as

$$\delta_2 = \int_0^\infty \frac{u}{U_\infty} \left(1 - \frac{\rho u}{\rho_\infty U_\infty}\right) dy \quad (12)$$

It represents **Momentum Deficit** caused by the boundary layer.

Now, in order to interpret the solutions in boundary layer theory, we define certain thicknesses. One of the problems with boundary layer theory is that remember u over U infinity goes very asymptotically to 1 and one cannot really say what is exactly the thickness of the boundary layer. It is a notional quantity. Boundary layer thickness is a notional quantity and we associate that with the notion that we shall say boundary layer thickness δ is the value of y where u over U infinity f' dash η is equal to 0.99 - that is sort of a convention that is followed.

(Refer Slide Time: 18:28)

But a more exact representation would be displacement thickness δ_1 and we define that as $\int_0^\infty \frac{\rho_\infty U_\infty - \rho u}{\rho_\infty U_\infty} dy$. Now, you can see what does that represent, it simply represents the idea that when a boundary layer is formed because of this viscosity affected region; if the boundary layer did not exist everywhere, the fluid will be flowing at the velocity U_∞ .

Because of the boundary layer, less fluid is flowing through this area and therefore, we define δ_1 as $\int_0^\infty \frac{\rho_\infty U_\infty - \rho u}{\rho_\infty U_\infty} dy$. You can see therefore, this quantity represents the amount by which the mass deficit has occurred because of the low velocity region in the vicinity of the wall.

In our case of course, since we are saying a uniform property flow ρ is equal to ρ_∞ and therefore, we will simply have $\int_0^\infty \left(1 - \frac{u}{U_\infty} \right) dy$ and if I say this is equal to $\int_0^{\delta_1} \left(1 - \frac{u}{U_\infty} \right) dy + \int_{\delta_1}^\infty \left(1 - \frac{u}{U_\infty} \right) dy$, then you will notice that this is really beyond δ_1 - the boundary layer thickness, u is in fact equal to U_∞ and therefore, that is equal to 0. So I get this is, $\int_0^{\delta_1} \left(1 - \frac{u}{U_\infty} \right) dy$.

This thickness is called the displacement thickness. Even if I choose η_{max} much greater than δ_1 in dimensionless form, it does not matter because all the integrations after that are 0 and therefore, displacement thickness is a far more precise quantity (Refer Slide Time: 20:32) than the quantity δ which is a sort of a fictitious value at f dash

eta equal to 0.99 and therefore, these thicknesses are much more reliable indicators of the thickness of a boundary layer.

Likewise, momentum thickness is defined as mass deficit multiplied by u over U infinity. It simply tells you the amount of momentum deficit that has been caused by the presence of the boundary layer. Again, if rho is equal to rho infinity then this simply becomes u over U infinity 1 minus u over U infinity.

(Refer Slide Time: 21:10)

Dimensionless Forms - L7($\frac{8}{14}$)

In incompressible flows $\rho/\rho_\infty = 1$. Hence,

$$\delta^* = \frac{\delta}{x} Re_x^{0.5} \quad (13)$$

$$\delta_1^* = \frac{\delta_1}{x} Re_x^{0.5} = \int_0^\infty (1 - f'(\eta)) d\eta \quad (14)$$

$$\delta_2^* = \frac{\delta_2}{x} Re_x^{0.5} = \int_0^\infty f'(\eta)(1 - f'(\eta)) d\eta \quad (15)$$

$$C_{f,x} = \frac{\tau_{w,x}}{\rho U_\infty^2 / 2} = 2 f'(0) Re_x^{-0.5} \quad (16)$$

These are evaluated from Similarity solutions at convergence.

Since u over U infinity is f' dash and dy is related to η , I can convert this definition to this form - δ star is equal to δ over X Re_x half δ one star δ one x , this is fairly straightforward to show.

(Refer Slide Time: 21:25)

The image shows handwritten mathematical derivations on a whiteboard. The main equation is:

$$\delta_1 = \int_0^{\infty} \left(1 - \frac{u}{u_\infty}\right) dy$$

It then shows the transformation to eta coordinates:

$$\eta = y \sqrt{\frac{u_\infty}{2\nu x}}$$

$$d\eta = dy \sqrt{\frac{u_\infty}{2\nu x}}$$

The integral becomes:

$$\delta_1 = \int_0^{\infty} (1 - f') \frac{dy}{\sqrt{\frac{u_\infty}{2\nu x}}} = \int_0^{\eta_{max}} (1 - f') d\eta$$

Further derivations show:

$$\delta_1^* = \frac{\delta_1}{x} \sqrt{\frac{u_\infty}{2\nu x}} = \int_0^{\eta_{max}} (1 - f') d\eta$$

and

$$\delta_2^* = \frac{\delta_2}{x} \sqrt{\frac{u_\infty}{2\nu x}} = \int_0^{\eta_{max}} f(1 - f') d\eta$$

where η_{max} is the value of eta at the edge of the boundary layer.

For example, I can define delta 1 as 0 to delta 1 minus u over U infinity d y and remember eta is y times under root U infinity by nu x. Therefore, d eta is simply d y times under root U infinity by nu x. So, if I change these values to eta, then you will see this become 0 1 minus f dash into d eta into under root nu x by U infinity and this will become eta at delta - eta at delta is what I shall call delta star- will be simply delta under root U infinity by nu x which is nothing but eta max in our case in a way or less than eta max.

So, now I get - delta 1 under root U infinity by nu x equal to 0 to infinity or whatever value you want to call it- 1 minus f dash d eta. If I manipulate this delta 1 by x into under root U infinity x by nu and that is equal to delta 1 by x Re x to the half equal to 0 to infinity 1 minus f dash d eta and this quantity I define as delta 1 star and analogously delta star delta by x U infinity by x by nu and then this is the value of eta at f dash eta equal to 0.99 and delta 2 star likewise is delta 2 by x under root U infinity by nu x is equal to 0 to infinity f dash 1 minus f dash d eta.

In actual numerical integration after the convert solution is obtained, I simply replace this infinity here by eta max and this also I replace by eta max. No harm done. So, I get values of delta 1 star delta 2 star delta star and (Refer Slide Time: 24:24) I recover the value of C f x as 2 f double prime 0 Re x to the power half.

(Refer Slide Time: 24:34)

Effect of Pressure Gradient $m - L7(\frac{9}{14})$

Excellent agreement with measurements of Nikuradze (1942)
and Liepman and Dhawan (1951) for Flat Plate BL ($m = 0$)

So, these quantities are evaluated after the solution has been obtained. I have obtained several solutions for U infinity equal to cx raised to m, which is our velocity profile. So, all positive values of m represent accelerating flow; all negative values of m represent the decelerating flow or the flow with an adverse pressure gradient.

This is the flow with a favorable pressure gradient. Remember beta is equal to 2m over m plus 1 - this is the wedge angle and I have also mentioned the wedge angle m equal to 0 represent the flat plate solution and I have already showed you 0.33 is the value of f double prime, delta star where f dash infinity is 0.99 turns out to be 4.9, delta 1 star is 1.727, delta 2 star is 0.663. As the flow accelerates, as compared to m equal to 0, you will see the boundary layer thickness is reducing as it should, because the flow is accelerating now and therefore, the viscosity affected region is thinner.

But in a decelerating flow, the viscosity affected region becomes thicker. Thinner the boundary layer, thickness or sharper is the velocity gradient and that is what you see here - there is an increase in the f double prime 0 value which increases the skin friction coefficient.

On the negative side, very interesting thing happened. At value of m equal to minus 0.091 which corresponds to beta equal to minus 0.2, f double prime is 0, this is the separating boundary layer and its thickness will be 7.42 compared to 4.9 for a flat plate

boundary layer. If you decrease the value rather of m still further, you will simply get a recirculation region near the wall and of course, that is not admissible in boundary layer theory. Incidentally look at this solution for m equal to 0 with a skin friction coefficient which is 0.33, $f''(0)$ is 0.33; this boundary layer has been measured for its skin friction and velocity profile.

The velocity profiles were made by a Russian scientist Nikuradze in 1942 and by Liepman and Dhawan in 1951 and since then several others have verified these measurements and on a boundary layer development on a flat plate. All of them predict excellently these values of 0.33 and 4.9 which is the boundary layer thickness. I have already showed you that m equal to 0, there is an exact solution which matches very well and so does it match with experimental data for m equal to 0. Experimental verifications have also been done for accelerating boundary layers and decelerating boundary and separation is indeed predicted when m equals minus 0.091 which is the separation pressure gradient parameter. The comments are, for m equal to 0 - δ^* is about 0.5 and $f''(0)$ is approximately 0.33.

(Refer Slide Time: 27:47)

Comments on Results - L7($\frac{10}{14}$)

- 1 For $m = 0$ (Flat Plate)
 $\delta^* \approx 5$ and $f''(0) \approx 0.33$
- 2 For $m > 0$ (Acc Flow)
 $\delta^* < 5$ and $f''(0) > 0.33$
- 3 For $m < 0$ (Dec Flow)
 $\delta^* > 5$ and $f''(0) < 0.33$
- 4 For $m \leq -0.091$ (Dec Flow)
 $\delta^* > 5$ and $f''(0) \leq 0$.
Hence, Separation occurs

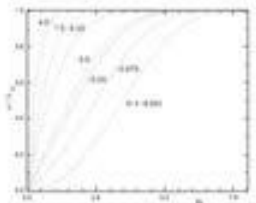

Figure: Velocity Profiles - Effect of m ($B_x = 0$)

Adv Pr Gr causes Flow thickening whereas Fav Pr Gr causes Flow thinning .

March 21, 2019 12:18

For an accelerating flow, m is greater than 0 and the boundary layer thickness now reduces; but the skin friction coefficient increases. I can see the velocity profiles obtained for m equal to 0 compared to the value of m greater than 0. You will see for m equal to 0, the boundary layer thickness is indeed just about 5 or say 4.92.

But the velocity gradients are indeed very sharp as the acceleration takes place. On the negative m side, m equal to decelerating flow, the boundary layer thickness goes on increasing and at m equal to minus 0.91, you see the velocity gradient at the wall- this is η , this is u over U infinity is in fact zero, as you can see the zero gradient very clearly. If you were to reduce m further, separation will definitely occur. So, this is the threshold value for separation to occur. What is our conclusion then? Adverse pressure gradient causes flow thickening compared to a flat plate boundary layer, whereas the favorable pressure gradient causes flow thinning. Now, we shall look at effect of suction and blowing. Remember our B_f is defined as V_w divided by U infinity into Re_x to the half and that should be a constant. That is what we have said.

(Refer Slide Time: 29:15)

Effect of Suction/Blowing - L7($\frac{11}{14}$)

- Recall that $B_f = (V_w(x)/U_\infty(x)) Re_x^{0.5} = \text{constant}$ for similarity solutions to exist.
- Therefore, since $U_\infty = C x^m$,

$$V_w \propto \left(\frac{U_\infty}{x}\right)^{0.5} \propto x^{(m-1)/2} \quad (17)$$

- Solutions obtained for $m = 0$ and $m = 1$ are shown on the next slide

0 Mar 31, 2015 15/18

(Refer Slide Time: 29:23)

The whiteboard shows the following derivations:

$$\beta = \frac{2m}{m+1}$$

$$B_f = \frac{Vw}{U_\infty} Re_n^{1/2} = \text{const.}$$

$$= \frac{Vw}{U_\infty} \sqrt{\frac{\rho U_\infty x}{\mu}}$$

$$= Vw \sqrt{\frac{\rho x}{\mu U_\infty}} = \text{const.}$$

$$\times \frac{1}{\sqrt{x}}$$

$$Vw \propto \frac{1}{\sqrt{x}}$$

$$Vw = \text{const.}$$

So, Vw over U_∞ under root $U_\infty x$ by μ should be constant or Vw into under root x by μ infinity should be a constant and therefore, Vw should be proportional to under root U_∞ by x or that is equal to proportional to x raised to m minus 1 divided by 2 and that is what I have shown here. Vw should be proportional to x raised to m minus 1 by 2. I am only going to consider two cases of m ; the solution can of course, be obtained for any value pressure gradient.

But you will see now that if m is equal to 0 that is on a flat plate if I want to obtain similarity solution for which m is equal to 0, U_∞ is a constant then Vw must vary for m equal to 0, Vw must vary under root x . For m equal to 1, Vw must be constant because m is equal to 1. Similarity solutions are possible for these two cases only when in case of m equal to 0, Vw varies as 1 over under root x and for m equal 1, Vw is constant. Both these solutions have great relevance in gas turbine cooling technology.

Near the leading edge of the blade, cooling air is injected through the leading edge at almost constant rate. Therefore, m equal to 1 case is very well taken care of by this Vw constant, whereas along the suction side there is a region where there is almost a constant pressure gradient m equal to 0 and that is where you inject fluid at a decreasing rate as 1 over under root x .

Effect of B_f ($m = 0$) - L7($\frac{12}{14}$)
Flat Plate Flow

B_f	$f''(0)$	δ^*	δ_1^*	δ_2^*
-2.0	2.063	1.87	0.439	0.212
-1.0	1.155	2.80	0.728	0.336
-0.5	0.723	3.60	1.04	0.456
0.0	0.330	4.90	1.727	0.663
0.3	0.134	6.33	2.69	0.868
0.5	0.0351	8.40	4.406	1.07
0.612	0.0	-	-	-

- $B_f < 0$ represents Suction
- $B_f > 0$ represents Blowing
- $B_f = 0.612$ represents Separation due to blowing

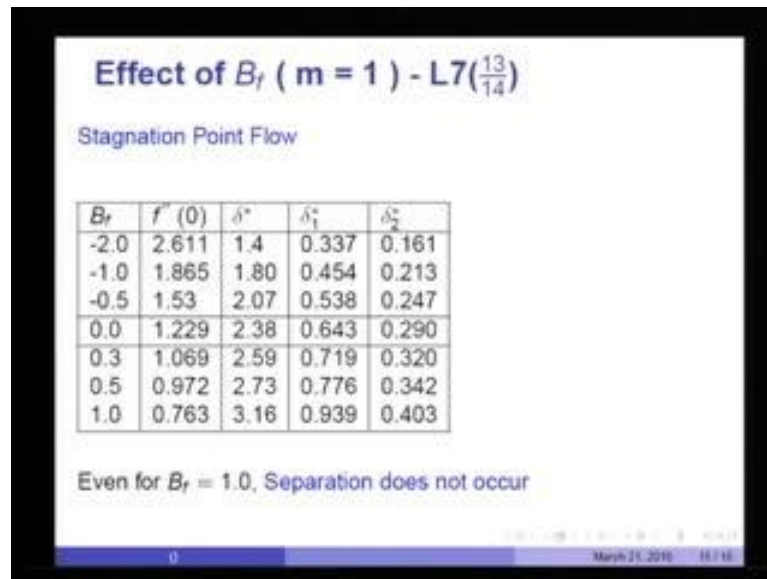

March 21, 2015 18/18

These solutions have affinity to the situations obtained in gas turbine blade. Remember this is the leading edge. So, this corresponds to m equal to 1. Here are the solutions for flat plate m equal to 0 and I have varied B_f on the negative side up to minus 2 and on the positive side of plus 2. B_f less than 0 represents suction, B_f greater than 0 represents blowing into the flat plate boundary layer,

Now, you can see what suction does? Suction reduces the thickness of the boundary layer and therefore, the skin friction increases. Thinning of the boundary layers always increases skin friction along with δ^* - even the displacement thickness and momentum thickness is also reducing and as a result the skin friction coefficient is increasing.

On the blowing side obviously the boundary layer thickness compared to no blowing would go on increasing as you can see with a decrease in skin friction and in fact at point B_f equal to 0.612, shear stress equal to 0 occurs, which means separation has occurred due to blowing.

(Refer Slide Time: 33:30)

We shall see now the case of m equal to 1. Very similar! Suction increases the skin friction whereas, blowing reduces skin friction but notice that in case of a stagnation point flow, no matter how hard you blow even up to B_f equal to 1, there is no indication of separation at all. It will require a very large value of B_f in fact unreasonably impractically large value of B_f to really cause separation in a stagnation flow.

That is understandable; there is an oncoming flow and if I want to close by separation of the boundary layer, then I must blow almost at the same rate as the oncoming flow is.

(Refer Slide Time: 34:22)

So, even up to B_f equal to 1, separation does not occur. Here are the velocity profile - for the flat plate and stagnation point flow. Let us look at the stagnation point flow first, you will see B_f equal to 0 curve is there and the velocity has become almost equal to 1 at η equal to about 5. Because of the suction, negative values of m minus 0.5 and minus 1- there is a thinning of the boundary layer with increasing gradient of velocity near the wall, so that increases the skin friction.

On the blowing side however, there is a thickening of the boundary layer but even with B_f equal to 1, there is no indication that separation would occur. On the other hand, if you look at the solutions for flat plate boundary layer, this is the solution for B_f equal to 0 which is going up to 5 and these are the solutions for suction obviously thinning the boundary layer.

By look at what happens for 0.5, boundary layer thickness is almost become double of what is it was for B_f equal to 0 and at 0.612 you get a 0 gradient velocity profile at the wall to indicating a separating profile. We have seen how velocity boundary layer solutions are influenced by the pressure gradient parameter m as well as the suction and blowing parameter B_f , how thinning and thickening of the velocity boundary layer takes place under the influence of these. We have also seen the merits of shooting method; it involves selection of η_{max} .

(Refer Slide Time: 36:11)

Iterative Algorithm - L6($\frac{4}{14}$)

- 1 Select values of m and B_f
- 2 Select η_{max} and step change $d\eta$
- 3 Guess $f'(0)$
- 4 Solve **three equations simultaneously** by R-K method
- 5 Check if value of $f'(\eta_{max}) = 1$ or NOT
- 6 If NOT, revise $f'(0) = \phi$ as

$$\phi(k+1) = \phi(k) + (1 - v(k)) \left[\frac{\phi(k) - \phi(k-1)}{v(k) - v(k-1)} \right]$$

where k is iteration number and $v = f'(\eta_{max})$.

- 7 Go to step 4
- 8 At Convergence,
 - 1 Print values of $f(\eta)$, $f'(\eta)$, $f''(\eta)$.
 - 2 Note value of $f'(0)$
