TRANSFORMATION OF E_{ij}

$$\begin{array}{ccc} E_{ij} & \longrightarrow & E_{mn} \\ (x, y, z) & (x', y', z') \longrightarrow & l_{ij} \end{array}$$

$$\sigma_{ij} \longrightarrow \sigma_{mn}$$

$$E_{mn} = l_{mi} l_{nj} \sigma_{ij}$$

Today, we will first consider transformation of strain Epsilon i j from one system of coordinates to another system of coordinates. Let us consider that Epsilon i j is defined in the system x, y, z. And you want to define this in a new system. Let us say an Epsilon m n, which is now given by the set x z and y z and z x dash y dash and z dash. Since, Epsilon i j is a second rank tensor, we can make use of the transformation rules for second rank tensor.

You have already been acquainted with the transformation of stresses sigma i j given in a system x, y, z to sigma m n which is to be defined in a system x dash y dash and z dash. So, we directly adopts the transformation rules, let us just consider that the direction cosines of the three coordinates are given by Epsilon i j with respect to the old coordinates.

Then, you can write that Epsilon m n, the new system is nothing but l m i l n j sigma Epsilon i j. So, this is defined in the new coordinates. And this is given in the old coordinates and these are the direction cosines of the new coordinates. So, these are the

direction cosines of new coordinates. So, it is a ((Refer Time: 03:26)) which is very similar to that of transformation of σ_{ij} .

This is the advantage, that it will work in tension irrespective of the field of the application. So, as long as the rank of the tension is the same, you can make use of the same rules for transformation. Now, we would like to consider definition strains in polar coordinates, you have considered the definition of strains in rectangular coordinates.

(Refer Slide Time: 04:17)

You will find that when dealing with geometries, which are have been circular consideration there in you will find advantage working in strains defined in polar coordinates. So, when a circular disc is loaded by external loading, which is undergoing deformation. And you will find that end point on the disc is going to have some displacement in the radial direction and some displacement in the tangential direction.

So, we will have to components of displacement in two dimensions, one is u which is the radial direction and v is the displacement in the tangential directions. And you must appreciate, that this u is going to be now a function of radial position and also the angular disposition of the points. So, if you consider this as the reference with respect to this reference, you can define a point by the angle θ .

So, this is going to be therefore, the point is going to be defined with respect to coordinate r θ . So therefore, u is going to be a function of r θ . Similarly, v is also

going to be a function of r and θ . Now, to find out the strains let us consider the summation of a element of the body upon loading. Let us consider that we have one element, which is shown here.

Let us consider an element, which is defined by this radial dimension Δr and the angular with position $\Delta \theta$. So, let us consider that this particular element is spanning at an angle of $\Delta \theta$. So, this is the angle $\Delta \theta$, and let us take this as the reference direction. And this angle is equal to, let us say θ and this is the centre of the coordinate.

Now, let us name the element as A, B, C and D. Now, upon loading this particular element is going to take up displaced position. Let us draw the displaced position to a larger scale. So, this is the displaced position, this is the position of A. Let us see that, this is new position of A and A dash. Similarly, new position of B and B dash, new position of D and D dash and the new position of C to C dash.

Now, the displacement that A has undergone in the radial direction is this much. Let us say that, this is the displacement u and the tangential displacement, which is exactly in the orthogonal direction, this is equal to v . The point B has undergone a displacement in the radial direction of this magnitude. And it is indicated by B, B 1 here and it has undergone a tangential displacement arc of this magnitude, which is B 1 to B dash.

Now, if I consider that, this u and v are continuous functions of r and θ . So, u and v are continuous functions of r and θ , over the domain of the body. We can consider this distance A, B to be given by it is a small distance. It is given by Δr and let us also consider that the distance of point O, point A from the centre, O is equal to r .

Now, if you consider that, this point B is located at a small distance from A. You can find out the displacement in the radial direction of B by ((Refer Time: 10:36)) Expansion. So, you can write displacement of B as u plus Δu , Δr multiplied by Δr . So, therefore the displacement of the radial direction, similarly the displacement B 1, B dash, which is in the θ direction. If you consider this to be θ direction, that can also be now, since this is v , you can now consider change of the B with distance A, B. And which is going to be, therefore v plus Δv Δr multiplied by Δr . You can now consider the point C, it has some movement in the tangential direction. So, let

us say, this $C C_1$ and you can write this distance $C C_1$ as v plus rate of change of v with respect to θ .

So therefore, Δv , $\Delta \theta$ and we have moved the distance of $\Delta \theta$. So therefore $\Delta v \Delta \theta$ into $\Delta \theta$ that will give us this distance. Similarly, it has moved by a distance in the radial direction, which is this one and C_1, C_{dash} . You can again, write in terms of the displacement in the radial direction of the point A. And therefore, this distance is going to be u plus Δu , $\Delta \theta$ multiplied by $\Delta \theta$.

So, this is what is the displacement in the radial direction of the point C? Now, let us do some construction, let us represent this point as A_1 . And then, we try to draw an arc here, passing through the point A_{dash} with centre O. We draw an arc passing through the point A_{dash} , let us consider that intersection of C_1, C_{dash} , here is C_2 . And similarly, we try to draw a line joining O to A_{dash} ; that makes an angle of let us say, Δ .

And now, we extend this line here, let us say the intersection of this radial line with B_1, B_{dash} is B_3 . We draw a line parallel to A_1, B_1 , which is this 1 . Let us say that, that let us say B_1, B_{dash} at point B_2 . So, therefore, this angle is since this is parallel to B. Therefore, this angle is equal to this angle and therefore, that is equal to Δ . You also indicate the angel approximate angle between this A_{dash}, B_{dash} and A_{dash}, B_3 is equal to γ_1 .

And similarly the angle made by the direction A_{dash}, C_{dash} with this arc here is equal to γ_2 with this we have ready to define the strains. So, if you now consider the strain in the radial direction, which is represented as ϵ_r . That is equal to limit Δr tending to 0 length of this element $A B$ tending to 0, change in the length of $A B$ divided by length of $A B$. Now, I would like you to know that point A has moved by u and point B has moved by u plus $\Delta u \Delta r \Delta r$. So therefore, the ((Refer Time: 16:14)) has been this distance minus this. So therefore, it is $\Delta u \Delta r$.

(Refer Slide Time: 16:24)

Therefore, this change in length of A B is nothing but this distance minus this u. So therefore, that will be Δu Δr ((Refer Time: 16:32)). So, we can now right limit Δr tending to 0 Δu Δr Δr . And length of A B is nothing, but Δr . So therefore, this strain in the radial direction is given by Δu Δr , which is the partial derivative of radial displacement with respect to r.

Similarly, if we consider Epsilon theta, Epsilon theta is defined as the change in the length of A C divided by the original length of A C, as the angle $\Delta \theta$ tends to 0. So therefore, this is $\Delta \theta$ tending to 0 change of A C divided by length of A C. Now, if we just consider, that A C is not moving in the radial direction at all. It has remain it has remained in the same radial disposition. And it has moved in the tangential direction only.

Then you see that, point A has moved in the tangential direction by v. And the point C has moved by v plus Δv $\Delta \theta$ $\Delta \theta$. And therefore, the ((Refer Time: 18:16)) movement has been this total minus v. Therefore, that is Δv $\Delta \theta$ $\Delta \theta$. So, that is one part which comes up from the tangential displacement of A C in the tangential direction only.

Now, if you consider, A C does not move in the tangential direction. It simply moves in the radial direction. So, it has moved from position A C to the position let us say, this to this. So, therefore, it has moved from this position move to this position. The length A C

was initially, A C was that is nothing but r into $\delta\theta$. Now, if it moves to this position A 1 to this, then in that case its length is going to change by you plus $r \delta\theta$ theta.

So, therefore, there will be a change if magnitude equal to r passive $\delta\theta$ minus are $\delta\theta$. So, therefore, that will be $u \delta\theta$. So therefore, to define that the ((Refer Time: 19:39)) in this case is going to be like this. Change in length of A C will be first of all of magnitude δv , $\delta\theta$, $\delta\theta$ plus the ((Refer Time: 20:04)). Change in position in a radial direction is $u \delta\theta$. And the original length is nothing but $r \delta\theta$. So, we find now the strain is given by u by r plus 1 by $r \delta v \delta\theta$. So therefore, the circumferential strain or the tangential strain is u by r plus 1 by $r \delta v \delta\theta$. Now, we have to consider the shear strain.

(Refer Slide Time: 21:20)

Let us consider now shear stain, which will be indicated as $\gamma_r \theta$. And this is given by limit δr tends to 0, $\delta \theta$ tends to 0. Change in the angle between that two directions, orthogonal directions A C and A B. So therefore, that is nothing but change in the angle CAB. Now, C has taken a position C dash, B has taken a position B dash and A has taken a position A dash.

So therefore, the angle change is given by we are the local orthogonal direction. Please note, that the local orthogonal direction here. This is the radial direction passing through A dash and this is the tangential direction passing through A dash. So therefore, the

change in angle is nothing but this angle $\gamma_1 + \gamma_2$. So therefore, this is nothing but limit Δr tending to 0, $\Delta \theta$ tending to 0 $\gamma_1 + \gamma_2$.

Now, I would like you to see this, that this angle γ_2 is nothing but approximately this distance divided by AC approximately, because the approximate AC^2 by AC . Therefore, this distance is nothing but... Since this distance is equal to u . Therefore, this distance is nothing but $u + \Delta u \Delta \theta$ multiplied by $\Delta \theta$ minus u .

So therefore, this distance is nothing but this magnitude. So therefore, this is given by only this quantity. And this distance AC is $r \theta$. So, therefore, this γ_2 , you can write γ_2 as 1 by $r \Delta \theta$ multiplied by Δu , $\Delta \theta$ del θ . And let us now see, what is γ_1 .

So, γ_1 is nothing but if you consider this total angle, total angle $\gamma_1 + \Delta$. That is nothing but this $B_1 B_2$ minus B_1 , this angle $\gamma + \Delta$ is given by this distance $B_2 B$ dash divided by this distance. Now, if you look into that this $B_1 B_2$ is nothing but v .

And this total distance we have got this total distance as $v + \Delta v \Delta r$ del r . So therefore, this total distance is nothing but given by this quantity. So, if you subtract B . Therefore, this distance here is going to be given by this magnitude. So therefore, $\Delta v \Delta r$ del r is this distance and this A_1, B_2 can be approximated by AB which is Δr . So therefore, this angle $\gamma + \gamma_1 + \Delta$ is nothing but it is approximately equal to $B_2 B$ dash divided by AB .

And this is equal to since $B_2 B$ dash is equal to $\Delta v \Delta r$ del r , you can approximate this by Δr . So therefore, it is going to be $\Delta v \Delta r$. Now, angle Δ is equal to this angle, if you consider that this distance OA is equal to r . Then, this angle is approximately equal to this distance divided by OA , which is going to be v by r . So therefore, Δ equal to v by r . So, we have now Δ is equal to v by r . So finally, we have γ_1 is equal to $\Delta v \Delta r$ minus v by r . So, you can now substitute the value in the expression of $\gamma r \theta$.

(Refer Slide Time: 26:58)

$$\begin{aligned}
 \epsilon_r &= \lim_{\Delta r \rightarrow 0} \frac{\text{change of } AB}{AB} = \lim_{\Delta r \rightarrow 0} \frac{\frac{\partial u}{\partial r} \Delta r}{\Delta r} = \frac{\partial u}{\partial r} \\
 \epsilon_\theta &= \lim_{\Delta \theta \rightarrow 0} \frac{\text{change of } AC}{AC} \quad AC = r \Delta \theta \\
 &= \lim_{\Delta \theta \rightarrow 0} \frac{\frac{\partial v}{\partial \theta} \Delta \theta + u \Delta \theta}{r \Delta \theta} = \frac{u}{r} + \frac{1}{r} \frac{\partial v}{\partial \theta} \\
 \gamma_{r\theta} &= \lim_{\Delta r \rightarrow 0, \Delta \theta \rightarrow 0} \Delta \text{ change in } \angle CAB = \lim_{\Delta r \rightarrow 0, \Delta \theta \rightarrow 0} (\gamma_1 + \gamma_2) \\
 \gamma_2 &= \frac{1}{r \Delta \theta} \frac{\partial u}{\partial \theta} \Delta \theta, \quad \gamma_1 + \gamma_2 = \frac{\partial v}{\partial r} = \frac{\partial v}{\partial r} \\
 \delta &= \frac{v}{r}, \quad \gamma_1 = \frac{\partial v}{\partial r} \frac{v}{r} \\
 \gamma_{r\theta} &= \lim_{\Delta r \rightarrow 0, \Delta \theta \rightarrow 0} \frac{1}{r} \frac{\partial u}{\partial \theta} + \frac{\partial v}{\partial r} - \frac{v}{r} = \frac{1}{r} \frac{\partial u}{\partial \theta} + \frac{\partial v}{\partial r} - \frac{v}{r}
 \end{aligned}$$

So therefore, now we have gamma r theta is equal to it is limit delta r tending to 0 delta theta tending to 0. Gamma 2 is nothing but 1 by r delta u delta theta and gamma 1 is nothing but delta v delta r minus v by r. So, that is nothing but 1 by r delta u delta theta plus delta v delta r minus v by F. So therefore, we find that the three components of strain in polar coordinates are here Epsilon r is delta u delta r. Epsilon theta is u by r plus 1 by r delta v delta theta. And gamma r theta is nothing but 1 by r delta u delta theta plus delta v delta r minus v by F. Let us now consider equilibrium equation in two dimensional rectangular coordinates.

(Refer Slide Time: 28:34)

EQUILIBRIUM EQNS. IN 2-D RECT. COORDS

$$\begin{aligned}
 \sum F_x = 0 \rightarrow \frac{\partial \sigma_x}{\partial x} \Delta y + \frac{\partial \tau_{yx}}{\partial y} \Delta y + x \cdot \Delta y = 0 \\
 \frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{yx}}{\partial y} + x = 0 \quad \dots (1)
 \end{aligned}$$

If you just consider a two dimensional object, like this subjected to loading at its boundary, it can also have load at internal points. Then, under the action of this loading stresses are going to develop at each and every point of the body. And we will have some constant or some relation satisfied by the stresses, at each and every point of the body. We would like to find them and they are nothing but the equilibrium equations.

We just concentrate on an element, which is of very small dimension. Let us say, it is of dimension Δx by Δy . And let us consider that the thickness of this body is uniform and the thickness in the z direction, thickness let us say t that is thickness in the z direction. Now, if I try to draw this element here large scale, let us show it like this. So therefore, this is Δy , this is Δx .

Now, the stresses that are going to come up on this face. Let us say, that the stress in the x direction is nothing but σ_x . So therefore, this is σ_x in the x direction. And the stress which is acting parallel to the face is nothing but τ_{xy} . Similarly, let us say that the stress acting on the face is nothing but σ_y and the shear stress on this face is equal to τ_{yx} .

These stresses and strains are continuous function if the body is continuous. So, if you want to represent the face from the other face, which is parallel to this. But, which is at a distance of Δx . We can make use of the Taylor series expansion. And we can write the stress on this face in the normal direction to be as $\sigma_x + \Delta \sigma_x \Delta x$.

So, therefore, that is the normal stress. Similarly, the shear stress acting on this face is going to be $\tau_{xy} + \Delta \tau_{xy} \Delta x$. Again it is the Taylor series expansion of this τ_{xy} and we have got this stress. If we consider the normal stress on this face, that is obtainable again from the normal stress here. And it is changing the y direction.

So therefore, we can write now this is $\sigma_y + \Delta \sigma_y \Delta y$. And the shear stress, which is acting here you can indicate that in terms of the τ_{yx} and this is $\tau_{yx} + \Delta \tau_{yx} \Delta y$. So, this is the shear stress.

Now, the body can be also subjected to forces at internal points, one of the type of force that is commonly placed is the body force, we indicate that as body force. Examples, like gravity forces, centrifugal forces. So, if the stresses are to be calculated under the action of the body forces. Then, we must try to bring in those types of forces at each and every point of the body.

Or if you are interested in calculating the stresses under the rotation under the action of rotation of the body, then we must bring in the inertia forces. These are all treated as body forces. So, it with depends on the volume. So therefore, we call these as body forces. So, if we consider that the body force acting at this point per unit volume in the x direction by capital X. And the body force part ((Refer Time: 34:15)) volume acting in the y direction is capital Y.

So, this is the element and the forces that are the acting on the element on it is boundary. Since, the body is in equilibrium under the action of the external forces and also the body forces. Each and every point of the body must also be in equilibrium. And therefore, this element which is subjected to forces at it is boundary like this. And at the same times it is subjected to forces X and Y.

We must have this particular element in equilibrium under the action of the volume forces. So, by the consideration of such equilibrium, whatever equations we get are nothing but equilibrium equations. Let us now consider the equilibrium in the x direction. So, some of the forces in the x direction must be equal to 0. What are the stresses that continue to the forces in the x direction, you have this component of stress, this component of stress. Then, these two shear components, this one and this one there are going to contribute to the forces in the x direction. On top of that, you are also going to have this force contributing to the force in the x direction.

Now, the force arriving out of this stress acting on the space whose area is nothing but Δy multiplied by t . So therefore, the force here is nothing but σ_x plus $\Delta \sigma_x \Delta x \Delta x$ multiplied by σ_y into Δt . And the force which is arriving out of this stress σ_x is nothing but σ_x into Δy into t .

So therefore, the net force which is coming out from these two components, in the x direction is going to be $\Delta \sigma_x \Delta x \Delta x$ multiplied by Δy into Δt ((Refer Time: 36:39)). Since, Δx into Δy into t is volume of the elements. So, we

can write the net force in the x direction from the stresses in the normal stresses in the x direction are nothing but $\Delta \sigma_x \Delta x \Delta y \Delta z$, where $\Delta y \Delta z$ is nothing but $\Delta x \Delta y \Delta z$.

Now, the other component which is going to come from this stress acting on this area, whose magnitude is $\Delta \tau_{xy} \Delta y \Delta z$. And similarly, this stress τ_{yx} is also acting on the similar area. So therefore, the net force is nothing but this incremental stress multiplied by the area $\Delta x \Delta z$. So therefore, the net force is going to be again $\Delta \tau_{xy} \Delta y \Delta z$ multiplied by $\Delta x \Delta z$.

And if you represent $\Delta x \Delta y \Delta z$ as ΔV , then we will have it as $\Delta \tau_{xy} \Delta y \Delta z$ multiplied by Δx , then this force which is also contributing to the stress to force in the x direction, which is nothing but $\Delta \tau_{xy} \Delta y \Delta z$. So therefore, you have $\Delta \tau_{xy} \Delta y \Delta z$ that is the force in the x direction. So therefore, sum of all these things must be equal to 0. So, ΔV is a common quantities finally, we can write the equation as $\Delta \sigma_x \Delta x + \Delta \tau_{xy} \Delta y + \Delta \tau_{yx} \Delta x = 0$. So, this is the equilibrium equation in the x direction. Now, we would like to also consider the equilibrium in the y direction.

(Refer Slide Time: 39:05)

The image shows a handwritten derivation on a piece of paper. At the top, there is a small diagram of a rectangular element with dimensions Δx , Δy , and Δz . The element is subjected to normal stress σ_y and shear stress τ_{xy} and τ_{yx} . The derivation proceeds as follows:

$$\sum F_y = 0 \rightarrow \frac{\partial \sigma_y}{\partial y} \Delta V + \frac{\partial \tau_{xy}}{\partial x} \Delta V + \gamma \Delta V = 0$$

$$\frac{\partial \tau_{xy}}{\partial x} + \frac{\partial \sigma_y}{\partial y} + \gamma = 0 \quad \dots (2)$$

$$\sum M_0 = 0 \rightarrow \tau_{xy} \Delta y \Delta z + \frac{\partial \tau_{xy}}{\partial x} \Delta x \Delta y \Delta z - \tau_{yx} \Delta x \Delta z - \frac{\partial \tau_{yx}}{\partial y} \Delta y \Delta x \Delta z = 0$$

Dividing by $\Delta x \Delta y \Delta z$:

$$\tau_{xy} - \tau_{yx} = 0$$

$$\tau_{xy} = \tau_{yx} \quad \dots (3)$$

So, if you now consider in a similar manner summation of the forces in the y direction equal to 0. That will give us like this, you are the force coming out in this y direction is

due to this normal stress, this normal stress. And due to this shear stress and this shear stress plus component due to the body force y .

Now, the differential force acting in the y direction due to normal stress is going to be this magnitude multiplied by the area, which is δx into t . And therefore, again you can write $\delta x \delta y$ into t as δv . So therefore, differential force is nothing but this $\delta \sigma_y \delta y$ multiplied by δv . So, $\delta \sigma_y \delta y$ multiplied by v , and from the shear stress τ_{xy} plus $\delta \tau_{xy} \delta x \delta x$. And this τ_{xy} acting here, the area of this face is nothing but δy into t . So therefore, the differential force in going to be simply due to this multiplied by the area is $\delta y t$. The component would be $\delta \tau_{xy} \delta x$ into δv .

So therefore, again this is going to be $\delta \tau_{xy} \delta x$ multiplied by δv plus the component due to Y is nothing but Y into δv . So therefore, this is Y into δv is equal to 0. So, you can now take the common factor out and therefore, second equilibrium equation is $\delta \tau_{xy} \delta x$ plus $\delta \sigma_y \delta y$ plus Y equal to 0.

Now, we will consider let us say that the centre point here of the element is O . Now, this element must also be movement equilibrium, and therefore if you write movement of all these forces about the centre point O equal to 0. Let us what are the forces that are going to cause movement. Since, this stress is going to be uniformly acting over this area.

Let me put it this way. That, we are considering this distance δY is so very small that this stress intensity can be taken to be uniform over this area. Similarly, for all other stresses you can them to be uniform over the stresses over they are acting. Therefore, the resultant of the force due to this stress will pass through this point. So, also due to this will pass through this point.

And by similar consideration, resultant force due to this stress and this stress will pass through this point. So therefore, the movement and again X and Y are going to pass through this point. So therefore, this movement caused by these two shear stresses in anticlockwise direction, these two shear stresses in the clock wise direction.

Now, if you try to consider the movement due to these two shear stresses, in the anti clockwise direction. It is nothing but we will have this $\delta \tau_{xy}$ working on an area of magnitude δY into t . And they are separated at a distance of δX . So therefore,

our movement magnitude is going to be nothing but that is τ_{xy} acting on an area of Δy into t and these two stresses are at a distance of Δx . So, that is the movement due to this and this component.

Now, if I consider this it is acting on an area of Δy into t . And it is acting at a distance of Δx . So therefore, we have a component like $\tau_{xy} \Delta x$ into Δx . And it is acting over an area of Δy into t and the momentum is Δx by 2. So therefore, it is Δx by 2, that is anticlockwise movement. Now, if we go for similar reasoning for this component τ_{yx} and τ_{yx} plus $\tau_{yx} \Delta y$ into Δy . This τ_{yx} will give us movement which is nothing but τ_{yx} multiplied by Δx into t multiplied by Δy . So therefore, that movement is going to be in clockwise direction.

So, you can write now you can write that τ_{yx} it is acting over an area of Δx into t . And the movement turn is Δy minus the movement due to this is going to be $\tau_{yx} \Delta y$ into Δy multiplied by Δx into t and the movement turn is Δy by 2. So therefore, we have $\tau_{yx} \Delta y$ multiplied by Δy and the area is Δx into t and the momentum is Δy by 2.

So, these are the two constituents. So, this is in the anticlockwise direction, this movement is in the clockwise direction. So therefore, they must add up to 0. Now, we are trying to talk about a distance Δx Δy very small. So, since Δx is very small and so also Δy . Therefore, we find that these terms are going, if we just remove the $\Delta x \Delta y$ into t term, this term is going to be left with Δx by 2 and this term is going to be left with Δy by 2. And you can neglect them. So finally, what we find is that you will have τ_{xy} minus τ_{yx} is equal to 0. Therefore, τ_{xy} is equal to τ_{yx} . So, this is the... So, let us name this as the 2nd equilibrium equation and this is the 3rd equilibrium equation.

So therefore, we have three equilibrium equations in two dimension. These are the three equilibrium equation in two dimensional rectangular polar coordinates. This one is in the equilibrium in the X direction, this is in the Y direction and this is the momentum equilibrium equation ((Refer Time: 47:16)).

Now, one important thing you must appreciate that the stresses at a point are such that the τ_{xy} space is acting on the face, which is perpendicular to the X direction. τ_{yx}

is the stress acting on the face perpendicular to the Y direction. These two stresses are acting on to orthogonal planes. And they are always going to be equal.

That is why some times you call, this tau y x to be complimentary to tau x y. Whenever, this is present this stress is also present. And obviously, this stress is always present along with this. So, whenever this stress is present we are also going to have this stress here. So, these complimentary stresses are equal. So, without further discussion we can always assume that tau x y to be equal to tau y x and that ensures moment equilibrium. Now, these three equilibrium equations if we make use of the tensor notation, it becomes again compact.

(Refer Slide Time: 48:22)

The image shows a handwritten derivation of equilibrium equations in two dimensions. A hand is pointing to the first equation.

$$\sum F_x = 0 \rightarrow \frac{\partial \sigma_x}{\partial x} \Delta V + \frac{\partial \tau_{yx}}{\partial y} \Delta V + x \cdot \Delta V = 0$$

$$\frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{yx}}{\partial y} + x = 0 \quad \dots (1)$$

$$\frac{\partial \tau_{xy}}{\partial x} + \frac{\partial \sigma_y}{\partial y} + Y = 0 \quad \dots (2)$$

$$\sum M_O = 0 \rightarrow \tau_{xy} \Delta y \Delta x + \frac{\partial \tau_{xy}}{\partial x} \Delta x \Delta y \frac{\Delta x}{2} - \tau_{yx} \Delta x \Delta y - \frac{\partial \tau_{yx}}{\partial y} \Delta y \Delta x \frac{\Delta y}{2} = 0$$

$$\Delta x \rightarrow 0 \quad \Delta y \rightarrow 0 \quad \tau_{xy} - \tau_{yx} = 0$$

$$\tau_{xy} = \tau_{yx} \quad \dots (3)$$

$$(1) \& (2) \rightarrow \sigma_{i,j} + x_i = 0 \quad \begin{matrix} i=1,2 \\ j=1,2 \end{matrix}$$

So, particularly this equation 1 and 2 we can write like this sigma i j comma j plus x i equal to 0 where i takes up value 1 to 2. So, also j takes a value 1 to 2. So, when you have i equal 1 and this comma indicates derivative of this component with respect to j. So therefore, you could give us two component and this since there repeated there is summation involved.

And therefore, it gives you the equation onto. So, this is also sometimes called equilibrium equations in two dimensions. Obviously, we can have the extension some in three dimension very easily. Then, in that case we are going to have the same form. But, we are going to have values of I varying from 1, 2, 3. So, j taking up values 1 2 3.

So, I leave it as an exercise for you to determine the equilibrium equations in three dimension. So, to summarize what we have done in this lecture is that, we have considered first of all the transformation of strains. Strain is a tensor like is stress tensor. And whatever rules apply to transformation of stress can be used for the transformation of strains. So, we have written the expression for strain transformation from one system to another system.

(Refer Slide Time: 50:22)

1) $\epsilon_{mn} = l_{mi} l_{nj} \epsilon_{ij}$
 (New) (D.C.'s) (Old)

2) $\epsilon_r = \frac{\partial u}{\partial r}$ $\epsilon_\theta = \frac{u}{r} + \frac{1}{r} \frac{\partial v}{\partial \theta}$
 $\gamma_{r\theta} = \frac{1}{r} \frac{\partial u}{\partial \theta} + \frac{\partial v}{\partial r} - \frac{v}{r}$
 $\epsilon_r = \frac{\partial u}{\partial r} = \frac{du}{dr}$
 $\epsilon_\theta = \frac{u}{r}$ $\gamma_{r\theta} = 0$

3) Eqn. Eqn. $\sigma_{\theta\theta} + x_r = 0$

Diagram: A circular cross-section of a cylinder with radius r . A radial displacement u is shown, and the condition $v=0$ is indicated. The displacement is labeled $u = u(r)$.

So, in the new system $m n$ Epsilon $m n$ is nothing but Epsilon $m i$ Epsilon $n j$ multiplied by Epsilon $i j$, where this is new and this is old set. And these are the direction cosines of the new set. Then, we have tried to consider definition of strains in polar coordinates. And we have found that Epsilon r is equal to partial derivative of the radial displacement u with respect to r .

That is the strain in the radial direction. And the strain in the circumferential direction it was nothing but u by r plus 1 by r delta v delta θ . And similarly, we had also derived gamma $r \theta$ which is nothing but 1 by r delta u delta θ plus delta v delta r minus v by r . Now, I would like you to note one situation, that there is a possibility that we may have displacements taking place only in the radial direction.

Think of the case, that you have a hollow cylinder and it is pressurized by internal pressure, under the action of this internal pressure. The points are going to move only in the radial direction. And the geometry of the body will not get distorted. And it is simply

going to expand. And therefore, each point is going to just have a displacement in the radial direction, you will not find any displacement in the tangential direction here.

So, v is equal to 0 and this u is going to be only dependent on the radial distance of the point. And therefore, this u is a function of r alone. So, in this particular case u is a function of r alone and v is 0. And therefore, in this case what are going to be the strains, you will find that here ϵ_r is just going to be $\frac{du}{dr}$, and since u is a function of r alone. So, you can write this thing as $\frac{du}{dr}$ total derivative. Rather than, partial derivative and ϵ_θ is going to be nothing but since v is not present. So, this part is 0, and the tangential strain is $\frac{u}{r}$ and shear strain $\gamma_{r\theta}$ here in u is not a function of θ . So, therefore, this is going to be 0 v is not present. So, therefore, this is 0 and v is 0, so therefore, everything is 0, so therefore, there is no shear strain.

So, what we find is that in this case there is no shear deformation of the body. And this is also clear from the changed configuration of the body. In this case it is simply going to maintain the radial symmetry or symmetry about the axis. So therefore, it is not going to have any change of angle between the radial and tangential directions.

What I mean is that, if you have a circle initially like this. The angle between the radial direction and tangential direction is 90 degree. And once, it gets displaced to a position like this. The angle between the radial direction and tangential direction is again 90 degrees. So therefore, there is no shear deformation here.

So therefore, in this case; obviously, the angle 90 degree is maintained. And therefore, the shear strain is 0 there and this is a typical case, where in you have only radial displacements. Then we consider of course, the equilibrium equations in 2D rectangular coordinates. And those equilibrium equations, we have written in the form $\sigma_{ij,j} + x_i = 0$.
