

Non-Linear Vibration
Prof. S.K. Dwivedy
Department of Mechanical Engineering
Indian Institute of Technology, Guwahati

Module - 1
Introduction
Lecture - 1
Introduction to Linear nonlinear systems

(Refer Slide Time: 00:23)

So, welcome to this course of non-linear vibration. This course is meant for the senior under graduate and post graduate students of Mechanical Engineering Department, Structural Civil Engineering Department and Aero Space Engineering Department. So, the course structure, the course content is given below. So, it is introduction, development of non-linear governing equation of motion.

(Refer Slide Time: 00:46)

Analytical solution methods:	Harmonic balance, perturbation techniques (Linstedt-Poincare', method of Multiple Scales, Averaging – Krylov-Bogoliubov-Mitropolsky), incremental harmonic balance, modified Lindstedt Poincare' techniques.
Stability and bifurcation analysis:	static and dynamic bifurcations of fixed point and periodic response, different routes to chaotic response (period doubling, torus break down, attractor merging etc.), crisis.
Numerical techniques:	time response, phase portrait, FFT, Poincare' maps, point attractors, limit cycles and their numerical computation, strange attractors and chaos; Lyapunov exponents and their determination, basin of attraction: point to point mapping and cell to cell mapping, fractal dimension.

And Analytical solution methods, Stability and bifurcation analysis then, numerical techniques. So, total 40 lectures, I will spend on this and module wise the division is like this.

(Refer Slide Time: 00:58)

Module	Lect. No	Content
1 Introduction	1	Introduction, Mechanical vibration: Linear nonlinear systems, types of forces and responses, Review of linear vibrating Systems
	2	Conservative and non conservative systems, equilibrium points, qualitative analysis, potential well, centre, focus, saddle-point, cusp point
	3	Commonly observed nonlinear phenomena: multiple response, bifurcations, and jump phenomena.

So, in the first module it is introduction, so I will take three classes to give brief introduction about this course. In the first class, I will tell about this introduction to this nonlinear vibration and linear and nonlinear mechanical vibration, then type of forces, resonances and I will review the linear vibrating system today. Then next class, I will

cover this conservative and non-conservative systems, equilibrium points, qualitative analysis, potential well, center focus, saddle-point and cusp points. In the third class commonly observed non-linear phenomena like multiple resonance, bifurcations, jump phenomena and different type of periodic, quasi periodic and chaotic responses.

(Refer Slide Time: 01:50)

2 Derivation of nonlinear equation of motion	1	Force and moment based approach, Generalized d'Alembert principle.
	2	Lagrange Principle, Extended Hamilton's principle, for Single- Multi dof and continuous systems
	3	
	4	Development of temporal equation using Galerkin's method for continuous system
	5	Ordering techniques, scaling parameters, book-keeping parameter. Commonly used nonlinear equations: Duffing equation, Van der Pol's oscillator, Mathieu's and Hill's equations.

Then, in the second module, I will cover this derivation of nonlinear equation of motion. So there, I will take five classes; in this module, I will cover different methods for deriving this equation of motion. So, the different methods include inertia based methods and energy base method. In case of inertia based method, it is force and movement based approach. So, there I will take the help of Newton second law or d'Alembert principle to derive the equation of motion, and in case of energy based approach Lagrange principle or extended Hamilton principle will be used.

And again, we will take the multi single, multi degree of freedom system and continuous systems for deriving this equation of motion. Several cases, case studies we will take to derive these equations of motions. Then, after deriving this Spatio temporal equation of motion for continuous system or temporal equation for the single to multi degree of freedom systems. So, we will go for finding the solution of the system. In case of continues system, it contains spatio temporal equation or initially, I will convert that thing to a set of temporal equation by using Galerkin method, and then after deriving the equation motion, the governing equation of motion. So, we have to do the ordering using

these ordering techniques and we may use some scaling parameter, book keeping parameter and will derive the governing equation of motion. So, particularly we will be interested to find the equation of motion of the type Duffing equation, Van Der Pol oscillator and Mathieu type of equations. So, besides that, we may study many other different type of systems.

(Refer Slide Time: 03:48)

Approximate solution method	9	Straight forward expansions
	10	Harmonic Balance method
	11	Linstedt-Poincare' method
	12	Method of Averaging
	13	Method of Averaging
	14	Method of Multiple Scales
	15	Method of Multiple Scales
	16	Method of Normal Forms
	17	Incremental Harmonic Balance method
	18	Modified Lindstedt-Poincare' method
Perturbation analysis method	19	Recently developed methods
	20	Recently developed methods

So, in the third module after deriving this equation of motion we have to solve those equations of motion by using some approximate methods. So, in those approximate methods we may use this harmonic balance method or we may go for some perturbation methods. Before doing this harmonic balance method we will do this straight forward expansions and we will see, what is the defect in this straight forward expansion method, also using this harmonic balance method we will see that by using very higher order harmonics, computationally solving this equation of motion is not, will not be proper. So, then we should, we will go for this perturbation analysis, where I will tell you about the Lindstedt-Poincare method, method of averaging, then method of multiple scales, method of normal forms, incremental harmonic balance method, modified Lindstedt-Poincare method and several recently developed methods.

So, after deriving this equation and by using this analytical or Perturbation methods we will convert our ordinary second order differential equation of motion to a set of hoisted differential equation of motion. So, for steady state solution we can find a set of

algebraic equations, which we can numerically solve to find the response of the system. Then, we will be interested to see the equilibrium, the equilibrium response, equilibrium points and their stability.

(Refer Slide Time: 05:23)

4 Stability and Bifurcation Analysis	21	Stability and Bifurcation of fixed point response, static bifurcation: pitch fork, saddle-node and trans-critical bifurcation, dynamic bifurcation: Hopf bifurcation
	22	
	23	
	24	Stability and Bifurcation of periodic response, monodromy matrix, Lyapunov exponents
	25	
	26	Different routes to chaotic response (period doubling, intermittency, torus break down, attractor merging etc.), crisis

So, after finding the responses we will be interested to study the stability and bifurcation of the responses. So, generally three different types of responses are observed in case of nonlinear system, 1 is fix point response; it may be trivial or non trivial response and then periodic response, quasi periodic response, and chaotic response. In all this cases, we will study the equilibrium points, there stability and the associated bifurcations. So, few classes I will take for stability and bifurcation of the fix point response. There I will tell about the static bifurcation and dynamic bifurcation. In case of static bifurcation, you may see super critical or soft critical pitch fork type bifurcation, saddle-node or trans-critical bifurcations and in case of dynamic bifurcation so you can see the Hopf bifurcation.

So, it may be super critical or soft critical type, similar to the fix point response. So, we will have periodic response also, in case of periodic response we will study the stability of the periodic response by finding the monodromy matrix, also we may use the Lyapunov exponent or we can go for the Poincare section of the response. Then we will see different routes to chaotic responses. So, the different routes include period doubling,

intermittency, torus break down, attractor merging and we will also study about the crisis observed in case of the chaotic responses.

(Refer Slide Time: 07:11)

5 Numerical Techniques	27	Time response, FFT, Frequency response curves
	28	Basin of attraction: point to point mapping and cell-to-cell mapping
	29	Poincare' section of fixed-point, periodic, quasi-periodic and chaotic responses
	30	Lyapunov exponents, Fractal dimensions
6 Applic ations	31-40	SDOF Free and Forced Vibration: Duffing Equation, van der pol's Equation: Simple or primary resonance, sub-super harmonic resonance, Parametrically excited system- Mathieu-Hill's equation, Floquet Theory, Instability regions; Multi-DOF nonlinear systems and Continuous system, System with internal resonances

So, in the fifth module I will tell you about different numerical techniques, where we will study the time response, FFT, frequency response and as you know in case of nonlinear system, a multi stable region will be observed or multiple solutions are observed then I will tell you different techniques to trace different branches of this responses. Then, as multiple solutions are available, we will study about the basin of attractions. In this basin of attraction we may use different techniques, two such techniques I will tell, that is one is point to point mapping and the second one is cell-to-cell mapping.

So, we will study then Poincare section of fixed point periodic, quasi-periodic, and chaotic responses Lyapunov exponents and fractal dimensions, we will use different numerical tools to find all these responses. So lastly, I will take around 10 classes to study different applications of the null linear systems. So, there we will study about the single degree of freedom system, multi degree of freedom systems and continuous system. In case of all these cases, we will study the free and force vibration. So, the equation already I told you may be of the type Duffing type, Van der Pol type equations. And in these cases you can see that we will see simple or primary resonances soft or super harmonic resonances. Then we may study the parametrically excited system, which are of the Mathieu-Hill types of equation. So, there we will use the Floquet theory and

we can study the instability region and some cases of internal resonances also will be covered in this course.

Also, I will give you few examples and the method of normal forms there I will use the book by A. H. Nayfeh.

(Refer Slide Time: 10:20)

So, we will also cover we will take the help of many journal papers. Particularly in this field of non-linear vibration, you can find the journals are very useful. So, the journals include “International Journal of Nonlinear Mechanics” by ELSEVIER, “Nonlinear Dynamics” by SPRINGER, then “Journal of Sound and Vibration” by ELSEVIER, “Journal of Vibration and Acoustics” ASME, “Journal of Dynamical Systems, Measurements and Control” by ASME, “Physics D: Nonlinear Phenomena” ELSEVIER, “Chaos, Soliton and Fractals” ELSEVIER, “International Journal of Nonlinear Sciences and Numerical Simulation and “Journal of Computational and Nonlinear Dynamics” ASME.

So, we will take several case studies from these journal papers and we will study the nonlinear phenomena associated in these systems. So, to start with let us see some

mechanical systems and we will see how the vibration phenomenon is occurring in those systems.

(Refer Slide Time: 11:32)

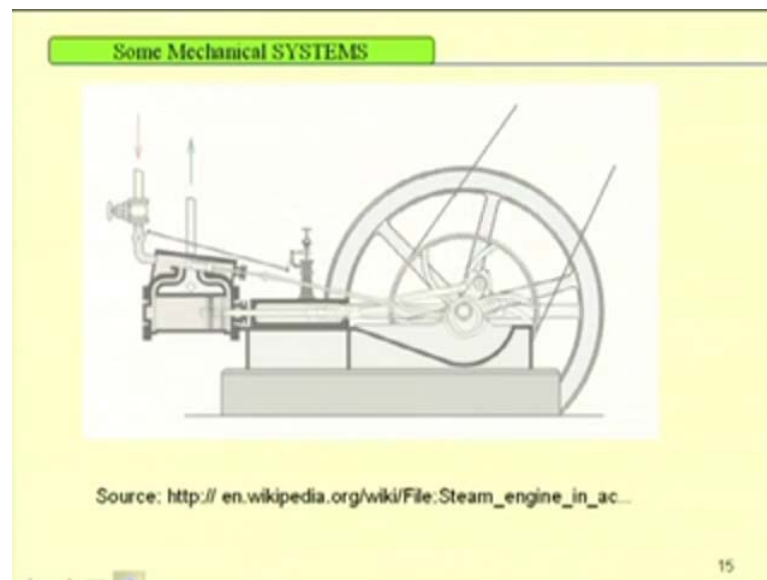

So, this page shows, so these are the some of the gears shown in these slides. This is a spur gear, so you can have spur gear, different types of gears, spur gear, vivel gears also you may have helical gears.

(Refer Slide Time: 11:54)

So, this is bevel gear, this is rack and pinion, this is worm gear and this is gear train. When more than two gears are used so, it is known as gear train. So, in these cases you can have a linear or nonlinear systems, you can model this rack and pinion or this gear systems by a linear rotary system for example, in this case of rack and pinion you can convert this system to a rotary and equivalent rotary system or an equivalent translatory system. So, if perfect rolling is assumed and if there is no manufacturing defect in that case you may neglect the vibration in the system but, due to the presence of manufacturing defect, the backlash clearance in the systems, most of the times you may see the vibration according to in this type of systems.

(Refer Slide Time: 13:00)

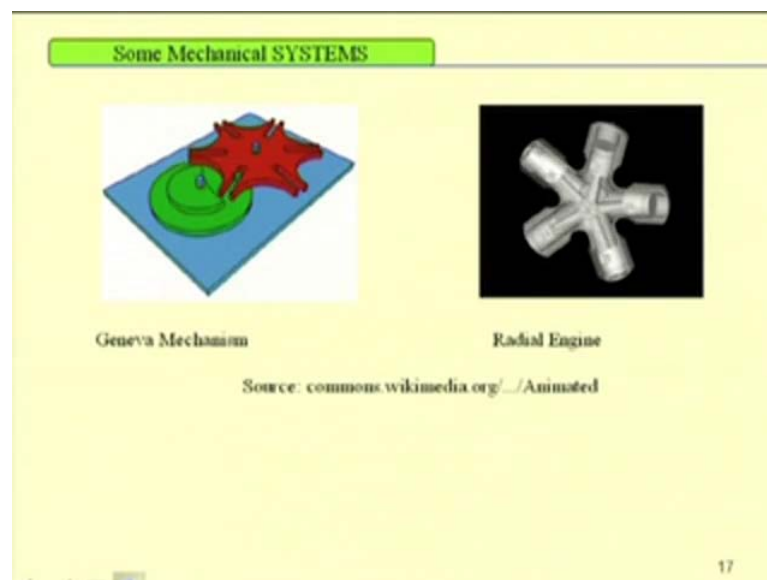

So, this is the animation for the steam engine, you can see different mechanical parts associated in the steam engine, you have a cylinder piston arrangement then this is the governor. The connecting rod, this is the crank, the crank is rotating this wheel. In this system, in this reciprocating system, one may observe inherent unbalanced force due to this inertia force associated in the system, also due to wear and tear in different mechanical parts one may observe severe vibrations.

(Refer Slide Time: 13:52)

This slide shows the internal combustion engine, here also you can have several parts, so this is particularly a slider crank mechanism, in this slider crank mechanism one can have this unbalanced primary secondary or harmonic forces in the direction of line of stroke. Also you can have different parts, like the scum and other different parts which will be subjected to vibration due to this inherent unbalanced force present in the system.

(Refer Slide Time: 14:35)

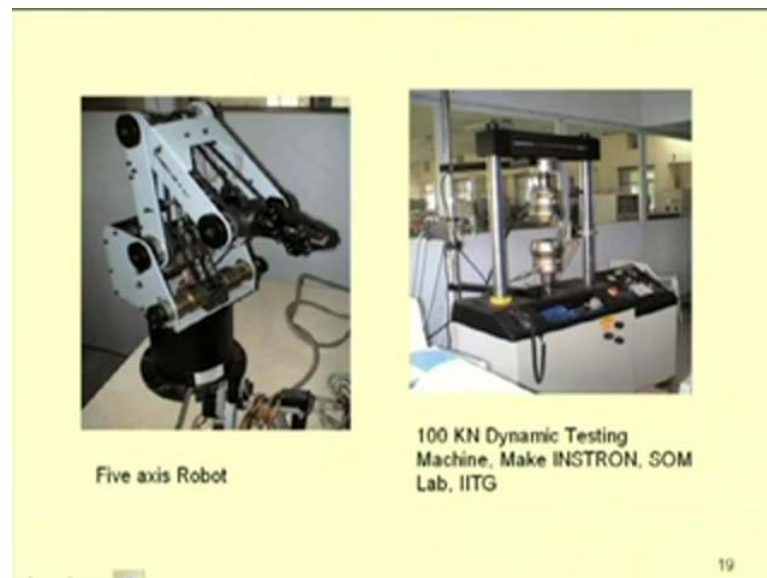

So, this is a rotary engine, this is Geneva mechanism, the animation of this systems are shown here.

(Refer Slide Time: 14:47)

Starting with these components of different machine parts, you can see different machines in this workshop, a lathe machine, this is a radial drilling machine, this is vertical drilling machine and this is shaper machine.

(Refer Slide Time: 15:11)

So, this is a five axis robot and this is u t m. So, in all these cases, one may observe that the parts are very rigid, due to this, to make it rigid or to make it very high stiffness one has to use heavy materials or make the components very heavy, but to reduce this weight for a different application for example, for space application to reduce the weight, one

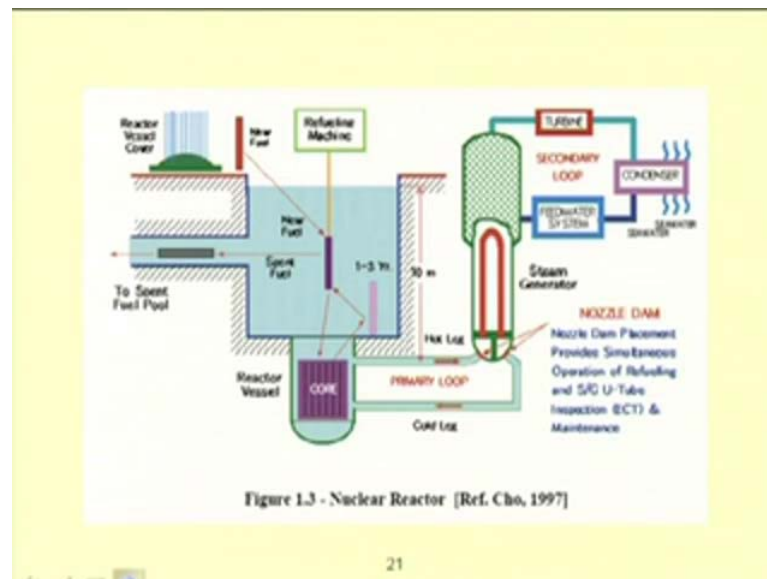

has to use light or flexible material. So, in case of flexible or light material the components will be subjected to vibration.

(Refer Slide Time: 15:57)

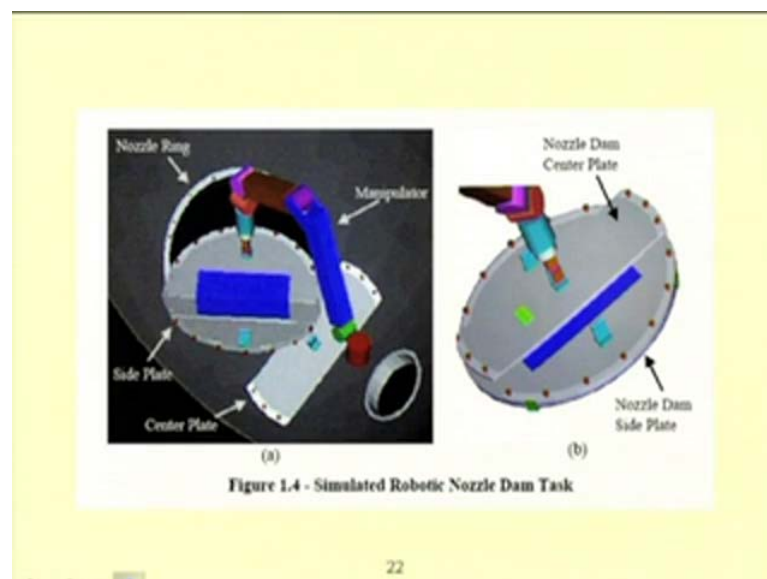

This slide shows the spot welding line, here several robots are used to manufacture a job, these robotic parts are very rigid, so it requires heavy inertia and due to heavy inertia one may use high rating time hours. So, to reduce the inertia one may make it of light weight, to make it light weight again the system will be flexible and will be subjected to vibration. So, this vibration one may model it has very small and that time one may take a linear system but, if the vibration is not small in those cases one has to consider the system to be nonlinear.

(Refer Slide Time: 16:52)

This slide shows a nuclear reactor.

(Refer Slide Time: 16:57)

So, in this nuclear reactor, to open the nozzle valve one may use a robot, one may do this thing manually or one may use a robot, but due to this radioactive nature, a robot is preferable, but in that case also lot of vibration will occur if one considers a flexible manipulator.

(Refer Slide Time: 17:19)

This is a patient positioning system, in this patient positioning system very accurate positioning is required. So for this precision positioning system, slight unbalance will cause severe damage to the patient. So in those cases, a nonlinear analysis or one may reduce the vibration by using nonlinear system analysis.

(Refer Slide Time: 17:55)

This is also another part of the patient positioning system, several parts are shown here, one may see these links if it is not rigid or if it is flexible, then it will be subjected to nonlinear vibration.

(Refer Slide Time: 18:16)

So, this is a long reach manipulator, this part in the long reach manipulator is used for repairing purpose in the satellite. In space crafts, due to weight constraint these long reach arms would be flexible, so due to the flexible nature they will be subjected to vibration. So, one cannot model this vibration to be small and in that case one will use the nonlinear vibration approach.

(Refer Slide Time: 18:50)

Here also a two link flexible manipulator is shown.

(Refer Slide Time: 18:57)

And this is also a two link flexible manipulator.

(Refer Slide Time: 19:01)

This is a spine biopsy simulator, in this case this needle part, who is touching this bone, it is flexible, due to that flexible nature it will be subjected to vibration.

(Refer Slide Time: 19:17)

This is a turbine, these blades are shown, due to unbalance in this, sometimes unbalance may occur in this turbine blade, so due to that severe vibration may occur in this system. To avoid that vibration, nonlinear analysis may be required.

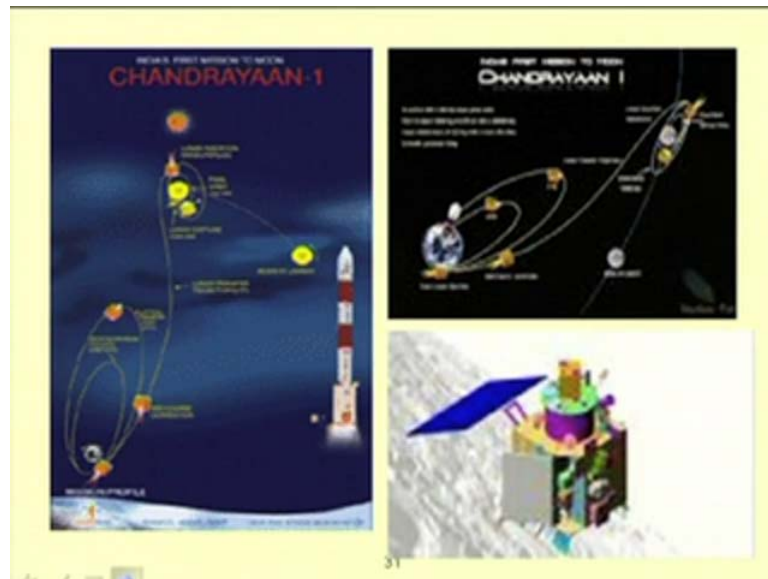

(Refer Slide Time: 19:35)

<http://www.grc.nasa.gov/WWW/K-12/airplane/index.html>

Also in these cases, these are turbines, nonlinear analysis will be required.

(Refer Slide Time: 19:41)

This is Chandrayaan, in this case also one may go for this nonlinear vibration analysis.

(Refer Slide Time: 19:52)

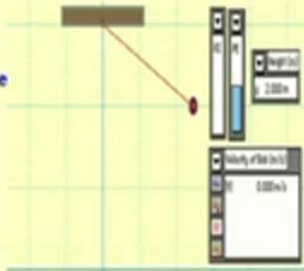

Definitions and Classification of Vibrating systems

Elementary Parts of Vibrating system

- > A means of storing potential energy
- > A means of storing Kinetic energy
- > A means by which energy is lost

The forces acting on the systems are

- > Disturbing forces
- > Restoring force
- > Inertia force
- > Damping force

The diagram shows a simple pendulum with a mass m suspended by a string of length l . The mass is displaced by an angle θ from the vertical. A free-body diagram of the mass shows three forces: a tension force T along the string, a weight force mg acting vertically downwards, and a reaction force R acting vertically upwards. The weight is decomposed into a component $mg \sin \theta$ along the string and a component $mg \cos \theta$ perpendicular to it.

Source: <http://www.glenbrook.k12.il.us/gb/sci/phys/mmedia/energy/pe.html>

32

So, now let us see, what are the elementary parts of a vibrating system? Here a very simple harmonic motion of a simple pendulum is shown, the simple pendulum, which contains a mass less thread with a bow here, it moves given an initial disturbance, so it moves. The kinetic energy, when it is at the top most position its velocity zero, so kinetic energy is zero. So, all the kinetic energy is converted to potential energy as now it is

coming back to this original position due to restoring force, this restoring force is coming due to gravity, so the potential energy decreases and it converts to kinetic energy.

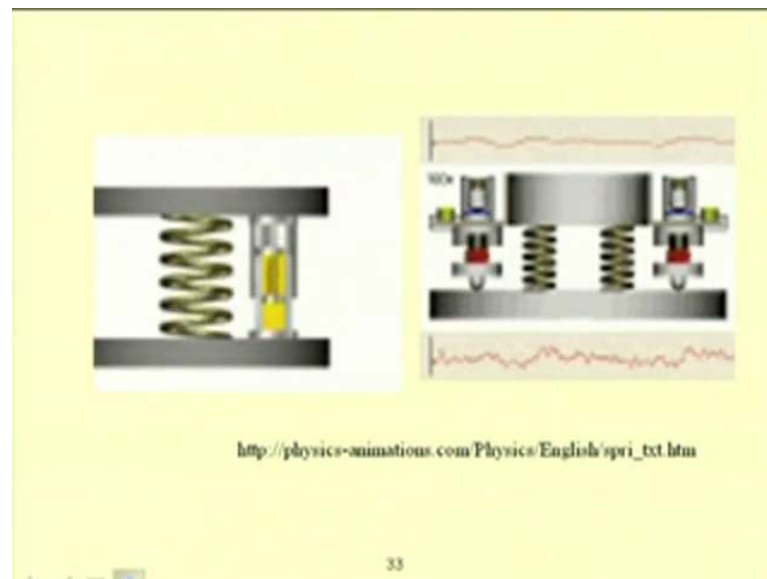

So, one can see this kinetic energy increase and decrease of kinetic energy, the total energy of the system is constant. So, in this case to have vibration in the system, one requires a initial disturbing force, then after the initial disturbing force is applied or the body is kept at this position due to a restoring force it comes back to its original position, that it is equilibrium position. But at its original position or at this equilibrium position as the body has high velocity, it is subjected to. As the body has, at this point high velocity, the velocity decreases and at this point the body has potential energy, all the potential energy is reduced and here the velocity, all potential energy is converted to kinetic energy so velocity is very high.

So, at this point due to inertia the body is moving to opposite direction, let it start from this position, so at this position due to inertia it has move up, here velocity is zero, again it will trace back to this original position. This oscillation will continue if this experiment is conducted in vacuum but if it is conducted in any ordinary room, thus vibration will come to or the pendulum will come to rest after sometimes, so due to presence of this air damping the vibration will be zero after sometimes. So, we have seen four different types of forces are acting in the system, one is the disturbing force, second one is the restoring force, third one is the inertia force and fourth one is the damping force, so each source is associated with one type of energy and one system parameter.

So, the restoring force is associated with the potential energy. In this case of pendulum, the potential energy is due to the gravity and then the inertia force, so inertia force is associated with the kinetic energy, so due to mass of the system it is it has inertia force, so inertia force is mass into acceleration and it acts in a direction opposite to that of the acceleration. And then a means by which energy is lost that is damping, so the damping force is associated with energy, energy loss due to dissipation energy. So, we have three different types of energy, one is the potential energy, second one is the kinetic energy and third one is the dissipation energy in the system. The elementary parts of the vibrating system associated with the inertia force is mass, associated with the potential energy is the stiffness and associated with the dissipation energy or a damping force is the damper.

So, in a system one may use a mass, a stiffness and a damping element. So in case of the stiffness for example, in this case due to this gravity, so it has gained this potential energy. But if one will take a cantilever beam or a beam so in that case, due to the elasticity of the system, elasticity E of the system, EI of the system, the body will gain this potential energy or the potential energy will be the strain energy in this case. So a vibrating system will have a mass, a spring element or a stiffness element then a damping element.

(Refer Slide Time: 25:25)

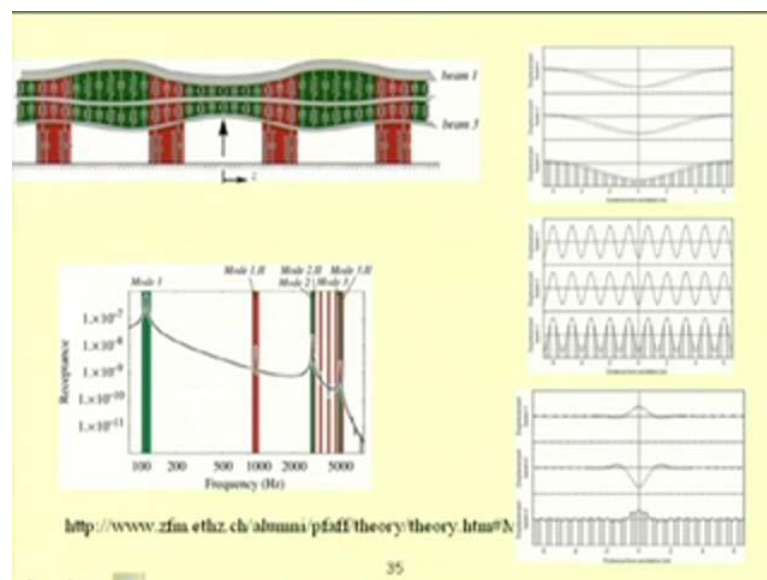

So, these slides show a spring and damper system, so this is the mass, during this vibration if it is very small or if the damping and the spring are assumed to be linear then one can see a linear motion or a simple harmonic motion.

(Refer Slide Time: 25:47)

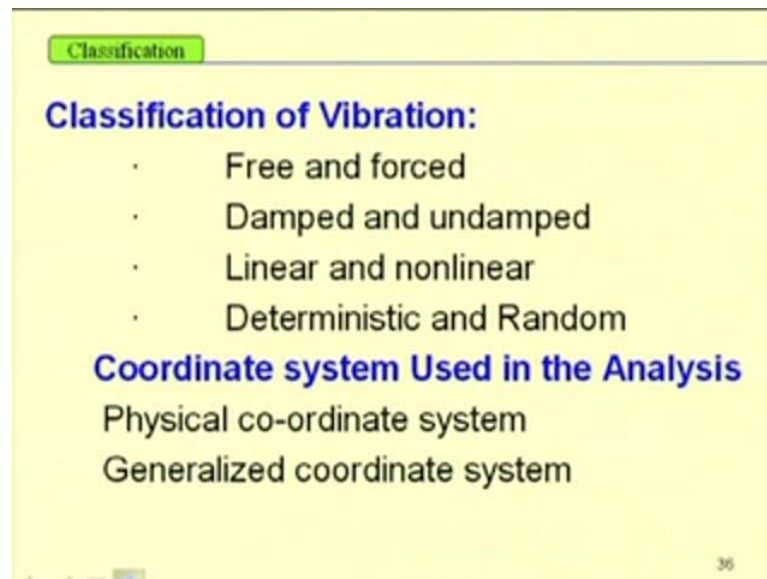

So, this slide, this animation shows a simple harmonic motion associated with a spring and mass system but, if the spring stiffness is not linear or if the spring is not linear so in that case the motion will be different type and in this course we are going to study what will be the motion if the spring is not a linear spring.

(Refer Slide Time: 26:24)

So, in this case the soil is model as different springs and the associated vibration is shown.

(Refer Slide Time: 26:35)

Classification

Classification of Vibration:

- Free and forced
- Damped and undamped
- Linear and nonlinear
- Deterministic and Random

Coordinate system Used in the Analysis

Physical co-ordinate system

Generalized coordinate system

36

So, we may classify the vibration into free or forced vibration type it may be damped or undamped type, linear or non-linear type then it may be deterministic or random. So, in case of free vibration after applying an initial unbalanced force or an initial disturbing force, the system is not subjected to any other force.

After applying this disturbance force, the system is left without any force and the system will vibrate and come to rest due to damping. Again this free vibration can be divided into 3 different categories, depending on the damping, it may be under damped, it may be critically damped or it may be over damped. And in case of force vibration, depending on the nature of the force we can have different type of response. While the free vibration will give rise to a transient response, which will die due to the presence of damping, in case of force vibration the system will oscillate with different amplitude and frequency, depending on the nature of the force. The force may be fixed it may be periodic it may be a stochastic type of force, so in case of periodic also the force may be of harmonic type or it may not be of type harmonic type. And in case of linear and nonlinear systems, we will divide the systems to be linear, when it obey the principle of super position and when it will not obey the principle of super position we can define the system to be nonlinear.

So, today we will see several examples, how to distinguish between a linear and nonlinear system. Also, we can have deterministic system and in case of deterministic,

we may have in case of deterministic response, we may have fix point response the response may be periodic, it may be quasi periodic or it may be chaotic. And the force may be a random type of force, the force may be a deterministic type of force also. The earth quake force is a random type of force, so in all these cases to analyze the system we required different coordinate systems.

The coordinate system maybe a physical coordinate system or it may be a generalized coordinate system. That thing we will discuss more in second module. So, one may follow 4 different steps for this vibration analysis.

(Refer Slide Time: 29:35)

The slide is titled "Steps for Vibration Analysis" in a green header. Below the title, there are four steps listed with red and blue arrows:

- > Convert Physical System to a simplified mathematical model
- > Determine the equation of motion of the system
- > Solve the equation of motion to obtain the response
- > Interpretation of the result for the physical system

Below the list, there is a handwritten equation: $M\ddot{x} + Kx + c\dot{x} = F$. Under the mass term M , it is written 12×12 . To the right of the equation, there is a handwritten vector notation $[F]_{12}$.

The slide number 37 is visible in the bottom right corner.

So, given a physical system, first one has to find the simplified mathematical model. To find the simplified mathematical model one may go for equivalent systems, so in these equivalent systems one may find mass, equivalent damping and equivalence stiffness of the system. After making a simplified model then one has to determine the equation of motion and after getting the equation of motion, one has to solve this equation of motion to obtain the response. And this response can be studied for bifurcation, stability and bifurcation analysis. After getting those responses and their stability, one has to interpret these results in terms of the physical system.

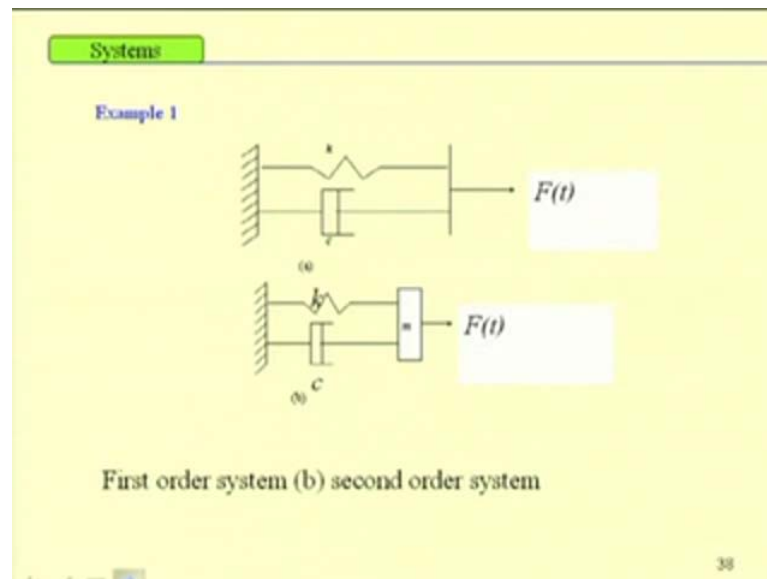

In case of equivalent system, to find the equivalent mass of the system, one can equate the kinetic energy of the original system with that of the equivalent system. Similarly, to

find the equivalent stiffness of the system, the potential energy of the original system would be equated with the potential energy of the equivalent system and in case of equivalent damping, one has to equate the dissipation energy of the original system with that of the equivalent system. We will see some examples, how to find this equivalent mass, stiffness and damping. And to model or to get simplified model, one can use this lumped parameter system, one can model the system as a single degree of freedom system two degree of freedom system or multi degree of freedom system or one can go for a continuous system modeling also. In case of single, two or multi degree of freedom system, one will have a one will have. In case of single degree of freedom system, one will have single differential equation of motion. In case of two degree of freedom system one will have a matrix equation differential equation in this form, that is $M \ddot{x} + Kx + C\dot{x} = F$. So, in this mass M is the mass matrix, K is the stiffness matrix, C is the damping matrix, x is the response and F is the force applied to the system.

So, F is a vector and x is a vector. In case of multi degree of freedom system, one has to solve this. If this is a n degree of freedom system for example, one can take a 12 storey building, so in that case one can write this a matrix by using a 12 is to 12 element. Similarly, the stiffness and damping matrix can be written with 12 is to 12 elements, and this force will be at F vector, so it will contain 12 components. So, one can use model reduction method or model analysis to convert this equation, if this equation, if this mass matrix and stiffness matrix and damping matrix are coupled, then one can use this model analysis method to convert these equations or to convert this mass matrix, stiffness matrix and damping matrix to a set of uncoupled differential equation of motion.

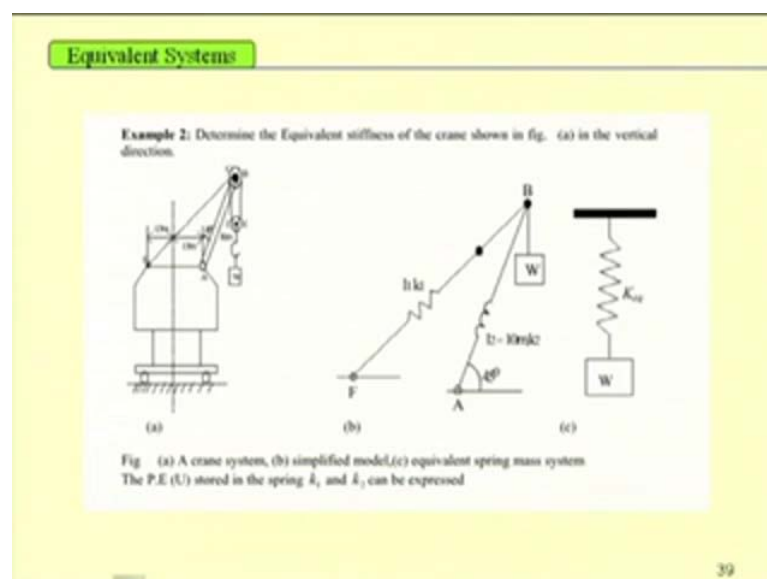

So, in that way by using model analysis method, one can have n number of uncoupled single degree of freedom equation. So, knowing the solution of a single degree of freedom system, one can find the response of a multi degree of freedom system also.

(Refer Slide Time: 33:51)

So, here several examples are given, this is only a spring and damper. The equation of motion can be written as, $Kx + C\dot{x} = F$, so this is a first order system. In this case, this is a spring, mass and damper system, the equation of motion can be written as $M\ddot{x} + C\dot{x} + Kx = F$, where x is the displacement of this, so $M\ddot{x} + C\dot{x} + Kx = F$, so this is a second order system. So, in these cases I am assuming the spring to be linear, that is why the spring force or the stiffness force I am writing equal to Kx but, if the spring is not linear then one cannot write this spring force to be Kx and in that case the equation of motion will be nonlinear.

(Refer Slide Time: 34:42)

So, to find equivalent stiffness, for example, let us take this crane system. In this crane system, this rod and this beam, so one can find the equivalent spring for this one and finally, as it is moving in this direction, the mass is moving in the downward direction, so, one can find one equivalent stiffness of the system.

So, as this rod is subjected to axial force then one can find the strain energy associated in this axial direction, one can find the strain energy here and for these two elements and then equate to that of the equivalent spring.

(Refer Slide Time: 35:35)

Equivalent Mass

Equivalent mass
Example 3: Determine the equivalent mass / moment of inertia of the gear-pinion system

$$T = \frac{1}{2} m \dot{x}^2 + \frac{1}{2} J \dot{\theta}^2$$

$$T_{eq} = \frac{1}{2} m_e \dot{x}^2$$

$$\dot{x}_e = \dot{x}$$

$$\dot{\theta} = \dot{x} / R$$

Fig. Gear and pinion system
 Equating the kinetic energy of the actual system with that of the equivalent system consisting of mass m_e having translational velocity \dot{x} the equivalent mass is obtained as follow.

$$\frac{1}{2} m_e \dot{x}^2 = \frac{1}{2} m \dot{x}^2 + \frac{1}{2} J \left(\frac{\dot{x}}{R} \right)^2 \Rightarrow m_e = m + \frac{J}{R^2}$$

Similarly one may think of an equivalent system consisting of a gear of moment of inertia J_e and rotating with angular velocity $\dot{\theta}$ and get J_e .

$$\frac{1}{2} J_e \dot{\theta}^2 = \frac{1}{2} m (\dot{\theta} R)^2 + \frac{1}{2} J \dot{\theta}^2 \Rightarrow J_e = J + m R^2$$

41

Similarly, taking this rack and pinion system, one can find the equivalent mass, one may convert this rack and pinion to an equivalent rotating system. In that case, at the speech point the velocity, is so if R is the radius of this pinion, then so R theta dot R theta dot, will be the velocity at the speech point for this pinion. And for the rack it is the x dot, it is the translational motion that is x dot, so at speech point the velocity is same.

So, one can write this x dot R theta dot equal to x dot or this is capital R, so R theta dot equal to x dot or one can write theta dot equal to x dot by R. Now, one can find the equivalent system, in this case the kinetic energy associated with this pinion equal to half J into theta dot square and for this rack one can write this is equal to half M x dot square. So, for this equivalent system, if it is translator, then I can write half M E into x dot square equal to half M x dot square plus half J into x dot by R whole square, so the

equivalent mass becomes M plus J by R square. Similarly, one can convert this thing, this whole system to an equivalent translatory system.

So, in that case, in case of equivalent translatory system the mass is this. In case of equivalent rotary system one can find the inertia associated with the system, so equivalent inertia equal to J plus $M R$ square. So similarly, by equating the dissipation energy one can find the equivalent damping or equivalent viscous damping of the system.

(Refer Slide Time: 37:58)

For example in case of coulomb damping, so if one draw the force versus \dot{x} , then so this is minus μn this is μn . So, in case of coulomb damping the force can be defined as F equal to $\mu n \text{sgn}(\dot{x})$. If the motion is harmonic, let x is harmonic, so in this case \dot{x} , so this is x versus time, so \dot{x} one can find \dot{x} is \cos , so if x is \sin form, then \dot{x} will be in \cos form \dot{x} versus t . So, one can see it changes sign two times in this, in one period. So, due to this change in direction of the velocity, the force will change from minus μn to plus μn . Due to this change in minus μn to plus μn the system is not linear, so the system may be considered to be nonlinear or this damping one can write as a nonlinear damping but, one can find the equivalent viscous damping for this system.

(Refer Slide Time: 39:37)

Equivalent Damping			
<p>Example 4. Table 1 shows the equivalent viscous damping for other types of damped system.</p> <p>Table 1:</p>			
Types of damping	Damping Force	maximumDissipation energy	Equivalent Viscous damping
Viscous damping	$c\dot{x}$	$\pi c\omega X^2$	c
Coulomb damping	$\mu N \operatorname{sgn}(\dot{x}), N = mg$	$4\mu NX$	$4\mu N / \pi\omega X$
Structural, solid or Hysteretic damping	$\pi\alpha\beta_s \operatorname{sgn}(\dot{x}) x $	$\pi\alpha\beta_s \int \operatorname{sgn}(\dot{x}) \dot{x} dt$	Exercise problem

So, in that case the equivalent viscous damping will be equal to four mu n by pi omega x. So, this thing one can obtain by finding the energy dissipation due to this coulomb force and one can find that energy dissipation, so for these portion of this motion so this is, if I am assuming x to be x sin omega t then, this is mu n or F of 2 x then from here to here, so this is minus mu n, so this length is two x. So, this is two x, again for this portion the motion is n. So, the total area associated with this dissipation energy, total area equal to 4 mu x, so this is mu n x this is 2 mu n x and this is mu n x, so total area or total dissipation energy becomes 4 mu n x. So, this dissipation energy one can equate with the equivalent dissipation energy, for an equivalent viscous damper and one can find this equivalent viscous damping. So, in this way one can find the equivalent systems, equivalent mass, equivalent stiffness and equivalent damping of the system.

(Refer Slide Time: 41:17)

Modeling of the system

- Single degree of freedom system
- Two degree of freedom system
- Multi-degree of freedom system
- Continuous system

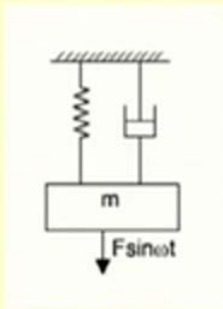

44

After finding the equivalent system or before going for the system, one can model or assume how to model the system. So, one may convert the system as a single degree of freedom system it may be a two degree of freedom system, multi degree of freedom system or continuous system.

(Refer Slide Time: 41:39)

Single Degree of Freedom Systems

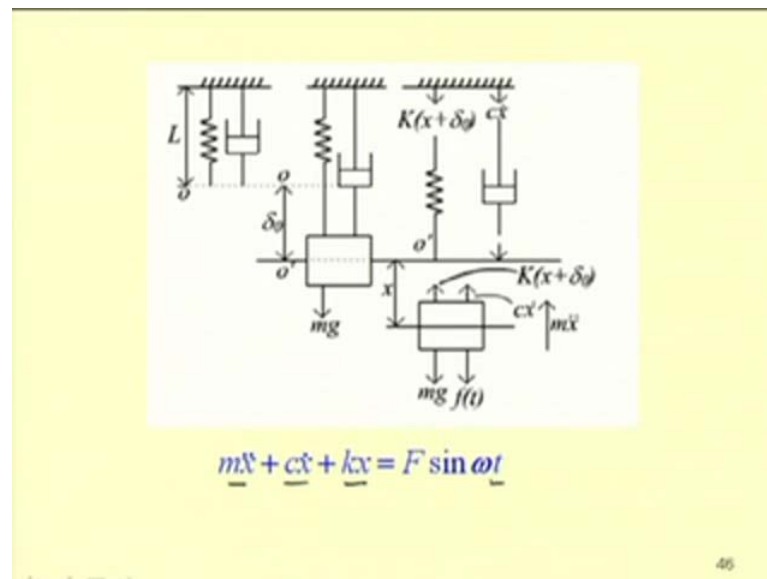

Steady state response due to Harmonic Oscillation

45

So, let us review the linear, single, multi degree of freedom system and continuous system.

(Refer Slide Time: 42:04)

A linear single degree of freedom system can be differentiated by a spring, mass and a damper, if it is subjected to a force $F \sin \omega t$, harmonic force, so then the equation of motion can be written in this form $m \ddot{x} + c \dot{x} + kx = F \sin \omega t$. This is inertia force $m \ddot{x}$, damping force $c \dot{x}$, stiffness force kx , equal to the external force.

So, one can find the response, the response will contain, 2 parts, one is the transient part and the second part is the steady state part. The transient part will die due to the presence of damping, so if it is due to damping and the steady state part will remain.

(Refer Slide Time: 42:40)

$$m\ddot{x} + c\dot{x} + kx = F \sin \omega t$$

The complete solution becomes

$$x(t) = \frac{x_1 e^{-\zeta \omega_n t} \sin(\sqrt{1 - \zeta^2} \omega_n t + \psi) + \frac{F}{\sqrt{(k - M\omega^2)^2 + (c\omega)^2}} \sin(\omega t - \phi)}{1}$$

So, the total solution of the system, equal to $x_1 e^{-(\zeta \omega_n t)} \sin(\omega_d t + \psi) + \frac{F}{\sqrt{k - M \omega^2}}$, so this is small m , $m \omega^2$ square whole square plus $c \omega$ whole square.

So, in this case the first part is the transient part and the second part is the steady state response of the system, the transient part, this x_1 and ψ depend on the initial condition and ϕ is the phase difference, this phase difference will give the time lag of or the time after which the response will occur when a force is applied to the system. So, we can have a rotating system the force we have applied in this system depending on different systems.

(Refer Slide Time: 43:51)

This force can be modeled in different ways for example, in case of a rotating unbalance, so due to the presence of a small rotating mass it will be subjected to a centrifugal force, so this centrifugal force can be divided into 2 parts, one vertical direction, one in horizontal direction. The vertical component will be $m e \omega^2 \sin \omega t$ and this horizontal part will be $m e \omega^2 \cos \omega t$ but, as it is restrained in this horizontal direction, so it can move only in the vertical direction, so the vertical force $m e \omega^2 \sin \omega t$ is the unbalanced force or is the resulting force acting on the system in this vertical direction. Due to that the system will be subjected to a vibration and one can have the response of the system, one can study the response of the system.

(Refer Slide Time: 44:50)

Similarly, one can study the whirling of a shaft, due to a bend shaft or due to the presence of one a centric mass in the disc, the system is subjected to a centrifugal force, so the plane containing the shaft access and the bearing line will rotate with increase in the speed of the shaft. So, that will cause whirling of the shaft, this whirling of the shaft is a transverse vibration of the system.

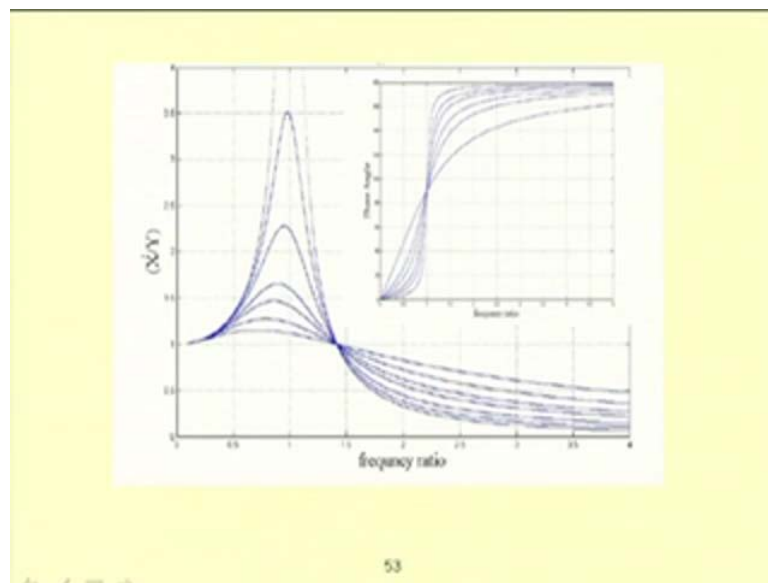

(Refer Slide Time: 45:34)

In this case one can find this r, that is the distance from the center of this bearing center to the shaft center, r by e in this form and if one plots that thing then, one can see this is

the phase angle versus frequency response, one can have the r by e response also. Also in this linear system one may study the support motion in most of the cases for example, in case of a vehicle moving on a road, so generally there is undulation in the road, this road can be modeled as a vibrating or support vibrating vibration of the support, this vibration can be modeled as a periodic, for simplicity it can be modeled as a periodic motion, y equal to $y \sin \omega t$, due to this motion the instrument or the vehicle will undergo vibration and the motion transmitted to the body due to the support motion can be given by this equation .

(Refer Slide Time: 47:01)

So, in this case if one plots x by y versus this frequency ratio, then one can observe that with increase in frequency of the support initially the response increases if there is no damping in the system then that amplitude becomes infinity but, due to the presence of damping the response reduces, one can observe irrespective of damping, the response one can have the response equal to x by y equal to one at ω by ω_n equal to root 2.

So, this value is ω by ω_n equal to root 2, so after root 2 one can observe with increase in damping the response amplitude increases. Also one may observe in this case when one operate the system at a frequency very away from the natural frequency then the phase angle is ϕ , phase angle ϕ equal to 180 degree and irrespective of damping at ω equal to ω_n the phase difference equal to π by 2.

(Refer Slide Time: 48:25)

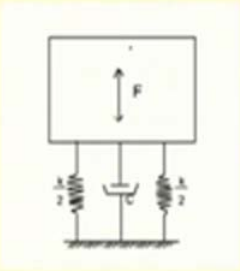

Vibration Isolation

Force Transmitted to the Support

$$F_t = \sqrt{(KX)^2 + (c\omega X)^2}$$

$$= KX \sqrt{1 + \left(\frac{2\zeta\omega}{\omega_n}\right)^2}$$

Amplitude of steady state response

$$X = \frac{F_0 / K}{\sqrt{\left[1 - \left(\frac{\omega}{\omega_n}\right)^2\right]^2 + \left(\frac{2\zeta\omega}{\omega_n}\right)^2}}$$

54

So, in case of support motion the support is giving a force or motion to the main system similarly, a force can be transmitted from the vibrating machine to the ground. So, that force transmitted to the ground or the force transmitted to the machine can be isolated by using the principle of vibration isolation. So the force if one calculate how much force is transmitted to the ground, this force is transmitted to through the spring and damper; one can find the force transmitted to the support equal to root over KX whole square plus $c\omega X$ whole square. So that is equal to KX root over $1 + 2\zeta\omega$ by ω_n whole square. The amplitude of steady state response as it is known to be F_0 by K , where F_0 equal to amplitude of this force, so a force of $F \sin \omega t$ or $F_0 \sin \omega t$ is applied to the equipment so this X . Amplitude equal to F_0 by K root over $1 - \omega$ by ω_n whole square whole square plus $2\zeta\omega$ by ω_n whole square.

(Refer Slide Time: 49:50)

For Force applied to the mass

$$\left| \frac{F_t}{F_0} \right| = \frac{1 + \left(\frac{2\zeta\omega}{\omega_n} \right)^2}{\sqrt{\left[1 - \left(\frac{\omega}{\omega_n} \right)^2 \right]^2 + \left(\frac{2\zeta\omega}{\omega_n} \right)^2}}$$

From Support motion

$$\left| \frac{X}{Y} \right| = \frac{1 + \left(\frac{2\zeta\omega}{\omega_n} \right)^2}{\sqrt{\left[1 - \left(\frac{\omega}{\omega_n} \right)^2 \right]^2 + \left(\frac{2\zeta\omega}{\omega_n} \right)^2}}$$

55

So, one can find the expression for force transmitted to the ground by the force of the, machine amplitude of the external force, so the expression is same as that you have seen in case of support motion.

(Refer Slide Time: 50:07)

So this X by Y or F t by F 0, one can get same curve, one can isolate the vibration of the system, if it is operated at a frequency higher than root 2. And in that case one may observe, when it is operating at a speed greater than root 2 times the natural frequency, presence of damping will increase the amplitude of the motion. And before omega or if

omega is less than the natural frequency, omega is the external frequency, if the external frequency is less than the natural frequency of the system, then a damper is a must. So, if there is no damping, so when one increase the frequency of the system, it reaches a frequency, it reaches a very high value of amplitude, it may be infinity at omega equal to omega n if there is no damping present in the system.

(Refer Slide Time: 51:14)

So, one can obtain the damping of the system by studying the sharpness of resonance. In this case, one can see in case of a single degree of freedom system, the maximum amplitude equal to $1/2\zeta$, so one can find the equality factor associated with this, and one can determine the damping of the system. Also, one may obtain the damping of the system from the free vibration of the system, for example in case if one takes the free vibration response of the system. So in that case by plotting the response of the system, if this is a under damped system, then the response amplitude can be will go on decreasing, and one can find different amplitude, this amplitude one can find. So, by dividing let this is X_1 this is X_2 , then this X_2 by or X_1 by X_2 \ln of X_1 by X_2 equal to $2\pi\zeta$ by root over $1 - \zeta^2$.

So, this is known as logarithmic decrement, from experiment one can find the damping of the system by finding the logarithmic decrement of the system. So, using one accelerometer or hygrometer, one can find the free vibration response of the system, so after getting the free vibration response, one can find the successive amplitude, and from

that one can obtain the logarithmic decrement of the system. After getting logarithmic decrement of the system, one can find damping of the system. So if the damping is very small, one can neglect this zeta square with respect to 1, so one can write this logarithmic decrement equal to $2\pi\zeta$ and one can easily get zeta from that.

Also, from this time response one can find the time period, one can find this ω_d , that is damped natural frequency of the system, equal to $2\pi/T$, if one gets the time period of the system then one can find this ω_d . So, the natural frequency of the system as it is related to the damped natural frequency by the expression $\omega_d = \omega_n \sqrt{1 - \zeta^2}$, one can obtain ω_n of the system. After getting the natural frequency one can find the system parameter or system stiffness, if mass of the system is known. So from the vibration response of this linear system, one can find or identify the system parameters.

One may use this vibration measuring instruments, which work on same principle as that of the support motion to manufacture this vibration measuring instrument. So, recalling this X/Y or Z/Y , Z is the relative motion, one can use the same system as an accelerometer when it is operating at a very low frequency and use as a seismometer when it is operated at a very high frequency. So today's class we have studied about the or we have reviewed the linear system, we know different types of nonlinear systems, and also we have seen the application of the course that is the nonlinear vibration system to a range of systems.

So, this course will be useful for the senior undergraduate or post graduate students in Mechanical Engineering Department, Civil Structural or Aerospace Engineering Department. So in the next class, we will see the difference between linear and nonlinear systems and we will also study the different phenomena associated with the nonlinear system.
