**Direct and oblique impulse**

Today, I am going to discuss about the impact of two bodies. We will discuss the direct and oblique impact. Although till now, we have studied the kinematics of particle, kinetics of particle and also we have discussed the kinematics of the bodies. Our assumption has been that bodies are perfectly rigid; that means they cannot deform. However, that when two bodies impact, there is some amount of deformation.

We will not study the deformation of the two bodies, but at least appreciate the concept that you know that two bodies when they collide, there is some amount of deformation and because of that both the bodies experience force. This point we will at least understand. Then, based on that you know that these bodies will affect each other. We will not really discuss those points that how much time it takes for collision of two bodies? We will assume that collision is instantaneous. As soon as the bodies impact, they separate out. If they do not separate out, in some cases, they remain distinct, you know that. Impact process finishes within no time that is our assumption.

We have to understand that this is idealization; because, in most of the cases this assumption may be justified. That is why we are going to do that. Although in later classes, you may study about the elastic and may be elastic context also. Another thing is that when two bodies are deforming, obviously, they will be of some finite size, but here we will not bring the size effect into the picture. We will assume that, as if there is an impact of two bodies of very small size. Therefore, they will be treated like a particle also.

(Refer Slide Time: 03:44)

Let us see, what is the process of impact? Impact refers to the collision between two bodies and is characterized by the generation of relatively large contact forces that act over a very short interval of time. In collision, two bodies make contact and then large amount of contact force is generated. If body a, applies some force on body b, then body b also applies the same amount of force on body, a. There are mainly two types of impacts.

We will study direct central impact and we will also study oblique impact. What do we mean by direct impact? When the two bodies are making contact and we draw a normal line; that means if you draw a line normal to the contacting surface and the bodies are having velocity along that normal line which is common normal of the two bodies, then that will be called direct impact. In that case, the velocities basically are also in one line.

One dimensional equation can describe the motion and the central impact means that the mass centers are in the same line. If you make an impact, something like this, that there is a this one, that body and you are doing like this, that suppose this rod is hanging and one bar comes and hits at this one, this velocity of this rod is like this. The velocity of this point on the rod will also be in this direction. However, the mass center is different. Therefore, although this impact is direct, because common normal is this and the velocities are along the common normal, but its mass

centers are not in the same line, this can be called direct non central impact. One can understand that also easily. But right now, we will not be discussing about that.

What happens if suppose two particles are making contact? Just see this figure that particle of mass  $m_1$  is going to collide with the particle of mass  $m_2$ . We can say small balls instead of a particle. Velocity of  $V_1$  is greater than  $V_2$  that means  $V_1$  is greater than  $V_2$  velocity of per mass  $m_1$  is more than velocity of mass  $m_2$ , before impact this is the situation. Since, this velocity is more than velocity of  $V_2$ , body of mass  $m_1$  catches body of mass  $m_2$  and then there is an impact. When there is an impact, what happens is that, this mass  $m_1$  is moving in that direction. It tries to move in that direction, the layers of that body  $m_2$  there is a deformation.

We know that, Hooke's law of elasticity. You know, stress is proportional to strain; that when you apply the stress then there is a strain generated and it is like something similar to spring type of thing. Although here, what happens, the situations are very complicated because the contact area also keeps on changing. But you can appreciate that if we draw a force verses time diagram, this is force here and this is time. In the beginning, just when the body has touched another body, at that time, the force is 0; then after that, force tries to increase. It is increasing and after that this keeps on increasing and then more and more deformation starts taking place.

Then what happens, as more and more deformation is taking place that means a force is being applied on body  $m_2$ . Therefore, its velocity is increasing; from  $V_2$  it is increasing. At the same time, the body  $m_1$  faces resistance, because that  $m_2$  applies the force in the opposite direction. Therefore, its velocity keeps on decreasing and gradually, a point comes. At that point, the velocity of both the bodies become same and the force has reached maximum. That time the velocity of both is same that is  $V_0$ .

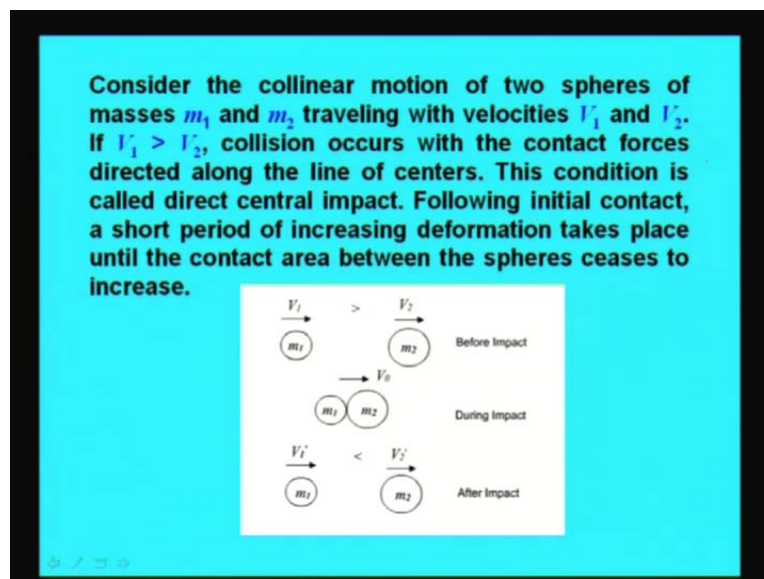

The condition also comes that both the bodies are moving with the same velocity, but then after that you know body  $m_1$  cannot press body  $m_2$  but if there is elasticity, because of elasticity there can be one situation that body  $m_1$  has pressed it to maximum extent and both the bodies are moving at the same velocity. Therefore, it is not applying the force and keeps on moving with that velocity; but usually what will happen, after that there is some elasticity and this body  $m_2$  will try to come back to the original position. Even body  $m_1$  will have tendency to go to the original position or that means recover from deformation. Therefore, it will start applying the

force in the opposite direction. Since, it will apply the force in the opposite direction that contact force will start decreasing like this and then finally, the contact force will become 0 at some point. This is the situation.

You know that contact force increases, reaches some maximum and then it comes down to 0. The exact profile may be different and it is not that necessary. This is just a schematic diagram showing that actually what may be going on. Once, in that process, a body  $m_2$  was applying the force on  $m_1$  in the opposite direction. Since they both were moving at the same velocity  $V_0$ , the velocity of  $m_1$  will decrease and it will become  $V_1$  prime. Simultaneously, the velocity of  $m_2$  will increase, because if  $m_2$  is applying a force on  $m_1$ ,  $m_1$  applies force on  $m_2$ . Therefore, during that process the velocity of this is increased. Therefore, velocity of particle  $m_2$  will become  $V_2$  prime. In this situation, after impact  $V_1$  prime is certainly less than  $V_2$  prime. In all the situations, you will see that when the two bodies collide and one body is moving with greater velocity, it contacts another body.

Then, after impact when they separate out, the velocity of the first body which was more will be necessarily less now and the another body's velocity will be more. That situation will be there after impact. This is the process which goes on inside this one and let me just describe it again.

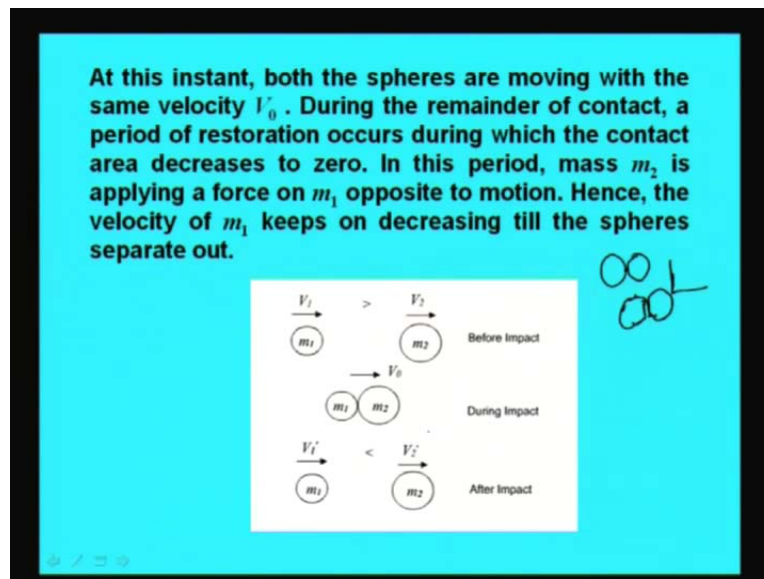

(Refer Slide Time: 12:09)

Consider the collinear motion of two spheres of masses  $m_1$  and  $m_2$  travelling with velocities  $V_1$  and  $V_2$ . If  $V_1$  is greater than  $V_2$ , then collision occurs with the contact forces directed along the line of centers. Contact forces are directed along the line of centers; that means along the normal. Therefore, this condition is called direct central impact, because the mass centers are in the same line and collision velocities are also taking along the common normal. So, this condition is called direct central impact.

Following initial contact, initial contact takes place then a short period of increasing deformation takes place. Deformation keeps on this one until the contact area between these spheres ceases to increase. Because after that velocity, both the velocities have become equal; naturally, that contact area will cease to increase. That is the situation.

(Refer Slide Time: 13:36)

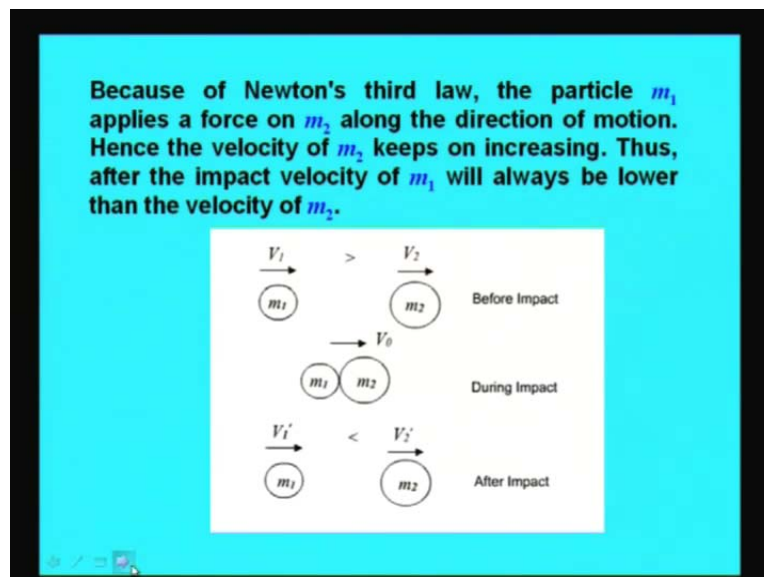

At this instant, both the spheres are moving with the same velocity  $V_0$ . When the contact area has ceased to increase; that means, contact area between the two spheres it is like this. In the beginning, there is like a point type of thing. That point is changing and contact area something like bodies have deformed. After deformation they become something like this. This is the type of thing. Contact area has increased. Like that, contact area keeps on increasing but direct contact area ceases. By that time, the force has reached the peak. After that the force cannot increase, because force is increasing because the body with greater velocity is pressing the body with a

smaller velocity and contact area is keep on increasing. The force will be proportional to the contact area. That is also there.

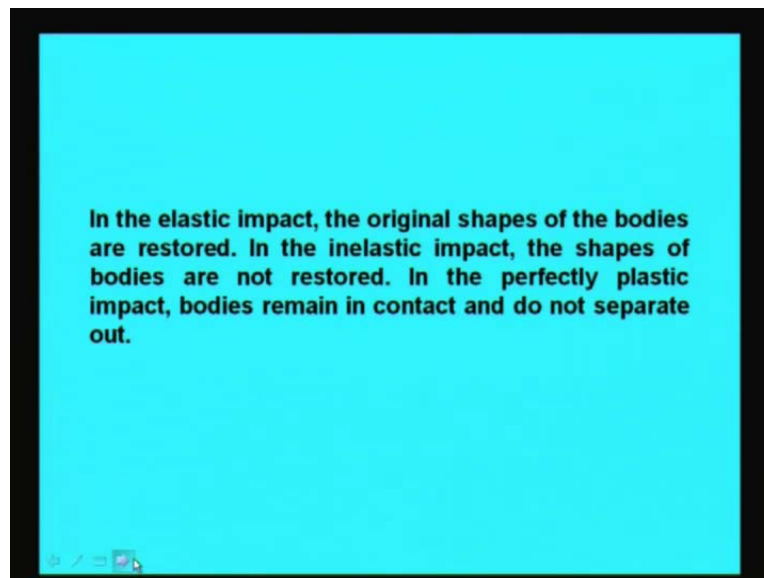

Therefore, at some instant, both the bodies have reached velocity  $V_0$ . During the remainder of contact, a period of restoration takes place that is called restoration. Restoration occurs, during which the contact area decreases to 0. The contact area will slowly decrease to 0 in the case of elastic. But sometimes, the elasticity cannot be fully recovered. That is another thing. Then certain amount of plastic deformation will also be present. In many cases, there is sufficient amount of elasticity. In this period, mass  $m_2$  is applying a force on  $m_1$  opposite to motion. Hence, the velocity of mass  $m_1$  keeps on decreasing till the spheres separate out. That is because, once the force has become 0, then they separate out because there is no force acting on that and the other body has picked up the velocity. Therefore, it will be separated out because other velocities are different.

(Refer Slide Time: 15:57)

Because of Newton's law, the particle  $m_1$  applies a force on  $m_2$  along the direction of motion. Hence, the velocity of  $m_2$  keeps on increasing. Thus, after the impact, velocity of  $m_1$  will be always lower than the velocity of  $m_2$ . That is the point and it has to be noted out.

(Refer Slide Time: 16:16)

In the elastic impact, the original shapes of the bodies are restored. In the inelastic impact, the shapes of bodies are not restored. In the perfectly plastic impact, bodies remain in contact and do not separate out because there is nothing. No force is applied to decrease the area. Therefore, they keep moving with the common velocity and there is a plastic deformation. So, therefore they do not separate out. That is what happens in the perfectly plastic impact.

(Refer Slide Time: 16:58)

Applying the law of conservative<sup>en</sup> of linear momentum

$$m_1V_1+m_2V_2=m_1V_1'+m_2V_2'$$

The above equation contains two unknown to be determined  $V_1'$  and  $V_2'$ . Thus one more equation is needed to solve the impact problem. For this purpose, the coefficient of restitution is defined. The coefficient of restitution  $e$  is the ratio of the magnitude of the restitution impulses to the magnitude of the deformation impulses.

7

We apply the law of conservation of linear momentum. If we consider although there is a force on one particle and or body sphere, similarly, there is another force on another sphere or body. If we consider them together, there is no external force acting on these bodies; that force is internal because one body applies a force on the other body, other bodies also apply the equal amount of force. Net outside force is 0. We assume that friction is not playing any role. In fact, what happens, the contact duration is so small in most of the cases that tremendous amount of force is generated. Compared to that small amount of friction, force is often negligible. Therefore, we can apply the law of conservation of momentum to this one; that is law of conservation of linear momentum.

Linear momentum: Initially the velocity of one body is  $V_1$  and the velocity of other body is  $V_2$  and after that it becomes  $V_1$  prime and  $V_2$  prime respectively. The first body attains the velocity  $V_1$  prime, second body is at  $V_2$  prime; this is after the impact. We are not considering that small duration when really the bodies are touching each other or that they are moving with the common velocity; that we are not considering only that well before the impact and well after the impact.

We get the equation  $m_1 V_1$  plus  $m_2 V_2$  is equal to  $m_1 V_1$  prime plus  $m_2 V_2$  prime. This equation contains two unknowns to be determined,  $V_1$  prime and  $V_2$  prime. Therefore, we must need two equations. Here, we are having only one equation. We cannot solve this thing. We need another one. So, one more equation is needed for this purpose and we define the coefficient of restitution. By that we can define that situation; that means, another equation that has to come from this is momentum equation, and another comes from the kinetic energy consideration. If the body is perfectly elastic then the kinetic energy must remain conserved.

We can write that equation also. We will have that one equation for the kinetic energy, initial kinetic energy. Then after that we will have another final kinetic energy. We will have for kinetic energy also. Therefore, by that we must know that how much fraction of kinetic energy has been lost. By that also, we can find out. Therefore, that is one way of doing that. But instead of doing the same thing, in a slightly different manner, we describe, that means loss in kinetic energy can be indicated by one quantity called the coefficient of restitution,  $e$ .

This coefficient of restitution  $e$  is the ratio of the magnitude of the restitution impulses to the magnitude of the deformation impulses. That is the thing. By this quantity, this is a very important quantity, suppose you say  $e$  is equal to one; that means, the kinetic energy is conserved. There is no loss of kinetic energy. If you say  $e$  is equal to 0, then there is a significant amount of loss of kinetic energy.

If you say  $e$  is equal to 0.5 then also there is some loss of kinetic energy. At  $e$  is equal to 1, there is no loss of kinetic energy. That is there, but we do not define that 1. We define the coefficient of restitution in a different way; ultimately it reads the same observation. We can relate these two kinetic energy also, but the thing is that here it becomes the coefficient of restitution.  $e$  is the ratio of the magnitude of the restitution impulses to the magnitude of the deformation impulses. What is the meaning of that restitution impulse and deformation?

See what impulse means force into time; product of force into time is called impulse. We integrate. That means, if we integrate  $F_{dt}$  or we draw that force versus time diagram. It is like, this is increasing and after that it is this one. Up till this point, there is a deformation process, because that body one is pressing the body two and contact area is increasing. After that it reaches a point; that means top point. Then the bodies try to restore their original shape. This is the restoration period or restore.

If we take the area up to this  $F$  that means  $F dt$  integrated this will be called deformation impulse. After that restoration period is there, if we take the area of this area will be called from here to here; that means, again this area, like this upto this will be called a restitution impulse. If we take the ratio of this area to that area then we get coefficient of restitution. If the contact is perfectly elastic, in that case, the deformation impulse will be equal to the restitution impulse. Whatever that impulse you have applied, same amount of impulse is getting recovered and therefore this ratio becomes 1. Otherwise ratio will be less than 1, if you do not allow bodies to restore.

That means, only it is rising, reaches the maximum contact area but then it is not separating out. In that case, if this is the situation, this is  $F$  and this is  $T$  and if it is increased but it is not coming down after that. Therefore, you have restitution impulse is 0; therefore,  $e$  will be 0 and one point has to be noted that you see what is this  $F$ ? This  $F$  is the force on which body you can consider the force on both the bodies, because if body  $a$  is experiencing the force, the other body is also

experiencing the same amount of the force. Net force, any way is 0 and this is what happens. Another case that if it keeps on applying the force and the restitution, one case I have shown like this and in another case, if the restitution does not take place, naturally that bodies will make contact, the force increases and after that this may become this one; that means, impulse may be 0 and it may just come down. Force may come down without making any change in the area.

(Refer Slide Time: 25:32)

Here, let us see it carefully during the formation period  $m_1$  and  $m_2$  these are the two bodies, body  $m_1$  is pressing body  $m_2$ , therefore body  $m_2$  is applying a force on body  $m_1$  and that force is given by  $F_d$ , therefore that I am showing the direction of the force  $F_d$  on  $m_2$  that is applied by body  $m_1$  in turn body  $m_1$   $m_2$  is applying a force on  $m_1$  and that is in this direction, this is the situation the force acting on each particle is  $F_d$ .

During restitution period, the force acting on each particle is  $F_r$ . Then also; the force is actually in the same direction, because this is  $m_2$ . After that, you know that this is  $m_1$ . So, during restitution period also bodies will experience the force that will be  $F_r$ .

(Refer Slide Time: 26:51)

For particle 1, the coefficient of restitution  $e$  is given as

$$e = \frac{\int_{t_0}^t F_r dt}{\int_0^{t_0} F_d dt} = \frac{m_1[-V_1' - (-V_0)]}{m_1[-V_0 - (-V_1)]} = \frac{V_0 - V_1'}{V_1 - V_0}$$

Here from 0 to  $t_0$ , deformation takes place and from time  $t_0$  to  $t$  restoration takes place.  $V_0$  is the velocity when both the particles are moving at the same velocity. Similarly

$$e = \frac{V_2' - V_0}{V_0 - V_2}$$

For particle 1, if we consider just the particle one, we can consider any one particle. We consider particle 1, the coefficient of restitution is given as  $e$  is equal to  $t_0$  to  $t$ . What is  $t_0$ ?  $t_0$  is that time at which bodies have started moving with the same velocity. The force has already reached maximum and this is like this. If bodies are deforming like this, this is time and this is  $F$ , this will be  $t_0$ .

From 0 to  $t_0$  deformation takes place and we have  $e$  is equal to  $t_0$  to  $t$ . Then, after that you have  $F_r$  into  $dt$ . Therefore, this becomes like this,  $t_0$  to  $t$   $F_r dt$  that force is keeping on increasing and it has become like this and divided by 0 to  $t_0$ . This  $t_0$  to  $t$  means this period  $t_0$  to  $t$ ; that is restoration period. Another one will be, if the bodies will not be able to recover, then the time they will not be able to apply the force also. So,  $F_r$  will become 0. Therefore, this will become obviously that upper part will become 0 and then it is 0 to  $t_0$   $F_d dt$ .

At this stage, you can apply the impulse momentum equation; change in the momentum is equal to the impulse. During this period, that means  $t_0$  to  $t$ , the velocity of the body one changes from  $V_0$  to  $V_1$  prime. We see that we have taken the direction of  $V_1$  prime assuming like this, but the force is acting in this direction. So, they are in the opposite direction.

To be consistent, we will take this as minus  $V_1$  prime, therefore what happens the final momentum is  $m_1$  minus  $V_1$  prime minus  $V_0$ . This will be 0 to  $t_0$   $F_d dt$  that is  $m_1$  minus  $V_0$ , because, here also the final velocity is minus  $V_0$  minus  $V_1$ . Therefore, we will be getting this and this will be equal to  $V_0$  minus  $V_1$  prime and divided by  $V_1$  minus  $V_0$ . We get one expression for  $e$  but although at this stage, we know that actually  $V_0$ , therefore, we have just written the expression like this. Here, from 0 to  $t_0$  deformation takes place and from time  $t_0$  to  $t$  restoration takes place.

$V_0$  is the velocity when both the particles are moving at the same velocity. Similarly, we can have similar type of equation for the second particle also. For the second particle, we will be having  $e$  is equal to  $V_2$  prime minus  $V_0$  divided by  $V_0$  minus  $V_2$ . So, both the things are there, so both equations. In this, we can eliminate  $V_0$  and we can get the expression for  $e$  like that.

(Refer Slide Time: 30:50)

Note that, in writing these equations, we have taken care to write the change in momentum in the same direction as the impulse. The time for the deformation is taken as  $t_0$  and the total time of the contact is  $t$ . Eliminating  $V_0$  between the two expression for  $e$  gives us

$$e = \frac{V_2' - V_1'}{V_1 - V_2} = \frac{|\text{relative velocity of separation}|}{|\text{relative velocity of approach}|}$$

In writing these equations, we have taken care to write the change in momentum in the same direction as the impulse. The time for the deformation is as taken as  $t_0$  and the total time of the contact is  $t$ . If we eliminate  $V_0$  between the two expressions for  $e$ , then between the two expressions, the expression for  $e$  becomes  $e$  is equal to  $V_2$  prime minus  $V_1$  prime divided by  $V_1$  minus  $V_2$ ; that means it is the relative velocity of separation  $V_2$  prime minus  $V_1$  prime, final velocity of body two and velocity of body one.

So, you see that both have started moving with a different velocity and they separate out with this relative velocity. This is called relative velocity of separation; other is called relative velocity of approach  $V_1$  minus  $V_2$ . So, this will be  $V_1$  minus  $V_2$ . So, the ratio of these two quantities is a positive quantity and that is called coefficient of restitution. That may range between 0 and 1.

(Refer Slide Time: 32:15)

Do you know, what is the value of  $V_0$ ? It can be found easily by applying the law of conservation of momentum.

$$m_1 V_1 + m_2 V_2 = (m_1 + m_2) V_0$$

Thus

$$V_0 = (m_1 V_1 + m_2 V_2) / (m_1 + m_2)$$

The value  $e = 1$  means that the capacity of the two particle to recover equals the tendency to deform. This condition is one of elastic impact with no energy loss. Let us find out the kinetic energy before and after impact for an elastic impact.

**Momentum Conservation:**

$$m_1 V_1 + m_2 V_2 = m_1 V_1' + m_2 V_2' \quad \text{----- (1)}$$

Do you know, what is the value of  $V_0$ ? Can we compute the value of  $V_0$ ? It can be found easily by applying the law of conservation of momentum; that means, we can say  $m_1 V_1$  plus  $m_2 V_2$  is equal to  $m_1$  plus  $m_2$  into  $V_0$ . So, we have  $m_1 V_1$  plus  $m_2 V_2$  is equal to  $m_1$  plus  $m_2$  into  $V_0$ . Thus we find out,  $V_0$  is equal to  $m_1 V_1$  plus  $m_2 V_2$  divided by  $m_1$  plus  $m_2$ . That way we can find out anyway the intermediate velocity  $V_0$ , which occurs for a short duration of time. Now, the value  $e$  is equal to 1 means that the capacity of the two particles to recover equals the tendency to deform. So, this condition is one of elastic impact with no energy loss. We have not talked about the kinetic energy, but now in this case, we will show that how there is no energy loss in this case.

Let us find out the kinetic energy before and after impact for an elastic impact. So, we have equations like we have equation for momentum conservation. We have  $m_1 V_1$  plus  $m_2 V_2$  is equal to  $m_1 V_1'$  plus  $m_2 V_2'$ .

(Refer Slide Time: 34:06)

$$\begin{aligned}
 &\text{As } e=1, \quad V_2' - V_1' = V_1 - V_2 \quad \text{-----(2)} \\
 &\text{From (2)} \quad V_2' = V_1 - V_2 + V_1' \quad \text{-----(3)} \\
 &\text{Hence (1) is written as} \\
 &\quad m_1 V_1 + m_2 V_2 = m_1 V_1' + m_2 (V_1 - V_2 + V_1') \\
 &\text{or} \quad m_1 V_1 + m_2 V_2 = m_1 V_1' + m_2 V_1 - m_2 V_2 + m_2 V_1' \\
 &\text{or} \quad m_1 V_1 + 2m_2 V_2 - m_2 V_1 = V_1' (m_1 + m_2) \\
 &\text{Thus} \quad V_1' = \frac{(m_1 - m_2)V_1 + 2m_2 V_2}{m_1 + m_2} \quad \text{-----(4)} \\
 &\text{Hence} \quad V_2' = V_1 - V_2 + \frac{(m_1 - m_2)V_1 + 2m_2 V_2}{m_1 + m_2}
 \end{aligned}$$

This is thing, as  $e$  is equal to one  $V_2$  prime minus  $V_1$  prime is equal to  $V_1$  minus  $V_2$ , because  $V_2$  prime minus  $V_1$  prime is what? It is the relative velocity of separation.  $V_1$  minus  $V_2$  is what? It is the relative velocity of approach. This is  $V_2$  prime minus  $V_1$  prime is equal to  $V_1$  minus  $V_2$  and now from this we get  $V_2$  prime, is equal to  $V_1$  minus  $V_2$  plus  $V_1$  prime. Hence, we can write one as this momentum by this  $m_1 V_1$  plus  $m_2 V_2$  is equal to  $m_1 V_1$  prime plus  $m_2 V_1$  minus  $V_2$  plus  $V_1$  prime.

We have substituted all these things or we will say,  $m_1 V_1$  plus  $m_2 V_2$  is equal to  $m_1 V_1$  prime plus  $m_2 V_1$  minus  $m_2 V_2$  plus  $m_2 V_1$  prime, or we take this portion, this side  $m_1 V_1$  plus  $m_2 V_2$  minus  $m_2 V_2$  is equal to  $V_1$  prime  $m_1$  plus  $m_2$ . Thus, we get  $V_1$  prime is equal to  $m_1$  minus  $m_2$  into  $V_1$  plus  $2 m_2 V_2$  divided by  $m_1$  plus  $m_2$ . So, we get this equation. Hence,  $V_2$  prime because  $V_2$  prime is  $V_1$  minus  $V_2$  plus  $V_1$  prime. So  $V_2$  prime is  $V_1$  minus  $V_2$  plus  $m_1$  minus  $m_2$  into  $V_1$  plus  $2 m_2 V_2$  divided by  $m_1$  plus  $m_2$ .

(Refer Slide Time: 36:11)

$$\begin{aligned}
 &= \frac{m_1 V_1 - m_1 V_2 - m_2 V_2 + m_2 V_1 + (m_1 - m_2) V_1 + 2m_2 V_2}{m_1 + m_2} \\
 &= \frac{(m_1 + m_2 + m_1 - m_2) V_1 + (m_2 - m_1) V_2}{m_1 + m_2} \quad \text{-----(5)} \\
 \\
 &KE = \frac{1}{2} m_1 V_1'^2 + \frac{1}{2} m_2 V_2'^2 \\
 \\
 &\text{using the values of } V_1' \text{ and } V_2' \text{ from (4) and (5) respectively,} \\
 \\
 &KE = \frac{1}{2} m_1 \frac{[(m_1 - m_2) V_1 + 2m_2 V_2]^2}{(m_1 + m_2)^2} + \frac{1}{2} m_2 \frac{[(m_2 - m_1) V_2 + 2m_1 V_1]^2}{(m_1 + m_2)^2}
 \end{aligned}$$

Then, after that we simplify this and we get something like this,  $m_1 V_1$  minus  $m_1 V_2$  minus  $m_2 V_2$  plus  $m_2 V_1$  plus  $m_1$  minus  $m_2 V_1$  plus  $2 m_2 V_2$  divided by  $m_1$  plus  $m_2$ , or we write this like this; this is  $m_1$  plus  $m_2$  plus  $m_1$  minus  $m_2 V_1$  plus  $m_2$  minus  $m_1$  into  $V_2$  divided by  $m_1$  plus  $m_2$ , now this is the expression for  $V_2$  prime.

We have expressions for  $V_1$  prime given by this equation 4 and then, we have expressions for  $V_2$  prime given by this equation. Now, we write the kinetic energy impact; that is half  $m_1 V_1$  prime square plus half  $m_2 V_2$  prime square. If we use the values of  $V_1$  prime and  $V_2$  prime from these equations 4 and 5 respectively, we get kinetic energy is equal to half  $m_1$  and  $V_1$  square; that means,  $m_1$  minus  $m_2$  multiplied by  $V_1$  plus  $2 m_2 V_2$  divided by  $m_1$  plus  $m_2$  whole square and this thing whole square on the top. Then plus half  $m_2$   $m_1$   $m_2$  minus  $m_1 V_2$  plus  $2m_1 V_1$  whole thing square divided by  $m_1$  plus  $m_2$  square. So, this is the thing and we have to do some algebra to simplify that.

(Refer Slide Time: 37:54)

$$\begin{aligned}
 &= \frac{1}{2} m_1 \frac{(m_1 - m_2)^2 V_1^2 + 4 m_2^2 V_2^2 + 4(m_1 - m_2) m_2 V_1 V_2}{(m_1 + m_2)^2} \\
 &\quad + \frac{1}{2} m_2 \frac{(m_2 - m_1)^2 V_2^2 + 4 m_1^2 V_1^2 + 4(m_1 - m_2) m_1 V_1 V_2}{(m_1 + m_2)^2} \\
 &= \frac{1}{2} \frac{[m_1 V_1^2 \{(m_1 - m_2)^2 + 4 m_1 m_2\} + m_2 V_2^2 \{(m_2 - m_1)^2 + 4 m_1 m_2\}]}{(m_1 + m_2)^2} \\
 &\quad + \frac{1}{2} \frac{[4(m_1 - m_2) m_2 V_1 V_2 + 4(m_2 - m_1) m_1 V_1 V_2]}{(m_1 + m_2)^2}
 \end{aligned}$$

That is half  $m_1$  and this will be  $m_1$  minus  $m_2$  square  $V_1$  square plus 4  $m_2$  square  $V_2$  square plus four  $m_1$  minus  $m_2$   $m_2 V_1 V_2$  divided by  $m_1$  plus  $m_2$  square plus half  $m_2$   $m_2$  minus  $m_1$  whole square  $V_2$  square plus 4  $m_1$  square  $V_1$  square plus 4  $m_1$  minus  $m_2$  into  $m_1 V_1 V_2$  divided by  $m_1$  plus  $m_2$  whole square. So, that expression you are getting. Then, one has to adjust this. So, half can be taken as common. So, half  $m_1 V_1$  square if you take, you will get  $m_1$  minus  $m_2$  square plus 4  $m_1 m_2$  plus you get a half is outside, totally outside of this, then  $m_2 V_2$  square then  $m_2$  minus  $m_1$  whole square plus 4  $m_1$  into  $m_2$  divided by  $m_1$  plus  $m_2$  square and then you get, half here is equal to 4  $m_1$  minus  $m_2$  into  $m_2 V_1 V_2$  plus 4  $m_2$  minus  $m_1$ ,  $m_1$  into  $V_1 V_2$  divided by  $m_1$  plus  $m_2$  whole square. So, this is this big expression you are getting.

(Refer Slide Time: 39:31)

$$= \frac{\frac{1}{2}[m_1 V_1^2(m_1+m_2)^2 + m_2 V_2^2(m_1+m_2)^2]}{(m_1+m_2)^2} = \frac{1}{2}m_1 V_1^2 + \frac{1}{2}m_2 V_2^2$$

Thus  $\frac{1}{2}m_1 V_1^2 + \frac{1}{2}m_2 V_2^2 = \frac{1}{2}m_1 V_1'^2 + \frac{1}{2}m_2 V_2'^2$

**Kinetic energy is conserved**

$$m_1 V_1 + m_2 V_2 = m_1 V_1' + m_2 V_2'$$

$$V_2' - V_1' = e(V_1 - V_2)$$

This is equal to half  $m_1 V_1$  square plus  $m_2 V_2$  square bracket  $m_1$  plus  $m_2$  whole square divided by  $m_1$  plus  $m_2$  whole square. If you simplify, then this becomes half  $m_1 V_1$  square plus half  $m_2 V_2$  square. Thus, we get half  $m_1 V_2$  prime square plus half  $m_2 V_2$  prime square is equal to half  $m_1 V_1$  square plus half  $m_2 V_2$  square.

That means the final kinetic energy of the two particles is equal to the initial kinetic energy of the two particles. The kinetic energy of the particles or bodies change, but combined thing remains same, in which  $e$  is equal to 1. That we have demonstrated. Similarly, we can of course demonstrate that when the bodies are making perfectly elastic contact, then the kinetic energies that get changed.

After describing these things, it must be clear that it is easy to solve the problems of direct central impact. There you have to write one equation for the balance of linear momentum, the other equation will come from the coefficient of restitution or theory; that means,  $V_2$  prime minus  $V_1$  prime is equal to  $e$  times  $V_1$  minus  $V_2$ . So, we will have two equations. So, there will not be difficulty in solving the problem of two unknowns. The two bodies are colliding, mass  $m_1$  and with velocity  $V_1$  it is moving. This another one is  $m_2 V_2$  is equal to  $m_1 V_1$  prime plus  $m_2 V_2$  prime.

Your goal is just to find out  $V_1$  prime and  $V_2$  prime. So, here it is like this, where one equation is this and the other equation is given by this.  $V_2$  prime minus  $V_1$  prime is equal to  $e$  times  $V_1 - V_2$ , is this is the thing. We got, velocity of approach is  $V_1 - V_2$ ; velocity of separation is  $V_2$  prime minus  $V_1$  prime. So, therefore this is the thing.

This  $e$ , value of  $e$  must be known. It is a property factor of so many things. It depends on the material, it depends on the size of the balls, it depends on which velocities they are. You know that making impact or collision. So, like that this must be, but it will be given in a problem. Therefore, this is given. So, you have 2 equations and 2 unknowns; that is  $V_1$  prime and  $V_2$  prime. This can be easily solved.

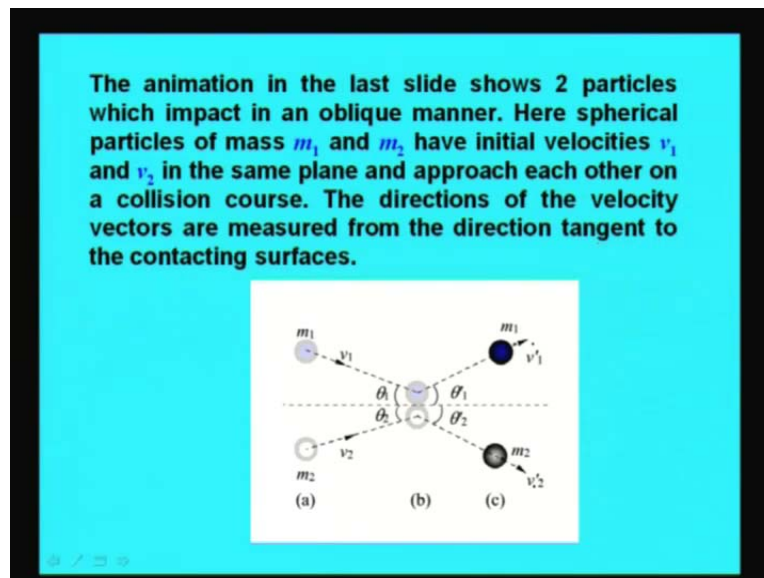

We need not write anything about the kinetic energy in this case. So, first this is the thing. So, that way you can solve the problems of direct central impact. Now, we will be discussing about the oblique impact problem.

(Refer Slide Time: 43:10)

In this case, the particles collide at certain angle and if you know that it may make contact, then the common normal is in some different direction. So, in this case, here the two bodies like we have two spheres. They are going here and they may be moving with some inclination.

(Refer Slide Time: 44:00)

In this case, two bodies will make collision and the situation will be like this. There is a particle  $m_1$  and there is a particle  $m_2$ ; both are moving with the velocity  $V_1$ , this is moving with the velocity  $V_2$ , both may contact at this point, collide and after that they separate. So, you know that when they make contact, this is the normal direction and this direction is the tangential direction.

Now, this part, this is making that angle  $\theta_1$  from this direction  $t$  and this is making angle  $\theta_2$  from here. Similarly, that from the tangent direction this particle  $m_1$  after the collision is making angle  $\theta_1$  prime and this is making an angle  $\theta_2$  prime. Therefore, this is  $V_1$  prime and this is  $V_2$  prime, this is  $m_1$  and this is  $m_2$ . The direction of the velocity vectors are measured from the direction of tangent to the contacting surfaces. So, this is the case of the oblique contact, because they are making contact at angle. So, these are the three situations here, shown a b and c.

(Refer Slide Time: 45:36)

Thus, the initial velocity components along the **t** and **n**-axes are

$$(v_1)_n = -v_1 \sin \theta_1, (v_1)_t = -v_1 \cos \theta_1,$$

$$(v_2)_n = -v_2 \sin \theta_2 \quad \text{and} \quad (v_2)_t = -v_2 \cos \theta_2.$$

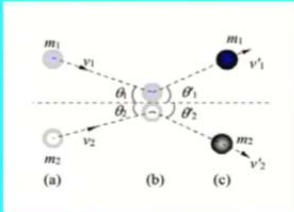

Note that  $(v_1)_n$  is a negative quantity for the particular coordinate system and initial velocities shown.

Thus, the initial velocity components along the t and n axes are, we can write that suppose, you have  $V_1$  we can resolve. Then along the normal,  $V_1 n$  is equal to minus  $V_1 \sin \theta_{11}$ , because it is coming downward. So, we have put a minus 1 and  $V_1$  tangential. If we say that minus  $V_1 \cos \theta_{11}$  in that direction, similarly,  $V_2 n$  is the velocity and that we have written minus  $V_2 \sin \theta_{21}$  and  $V_2 t$  is equal to minus  $V_2 \cos \theta_{21}$ .  $V_1$  depends on the coordinate system that whether you call that  $V_1 n$  positive or negative. If you take that, for this particle if you take upward direction as y, then it is like this.

(Refer Slide Time: 46:42)

States of 3 different situations are shown below. For given initial conditions of  $m_1$ ,  $m_2$ ,  $(v_1)_n$ ,  $(v_1)_t$  and  $(v_2)_n$ ,  $(v_2)_t$ , there will be four unknowns, namely  $(v_1')_n$ ,  $(v_1')_t$ ,  $(v_2')_n$  and  $(v_2')_t$ . The four needed equations are obtained as follows:

(1) Momentum of the system in the  $n$ -direction. This gives,

$$m_1(v_1)_n + m_2(v_2)_n = m_1(v_1')_n + m_2(v_2')_n$$

This situation is shown now. States of 3 different situations are shown below. For given initial conditions of  $m_1$ ,  $m_2$ ,  $V_1 n$ ,  $V_2 n$ , there will be now four unknowns. We have got four unknowns namely, what are the four unknowns?  $V_1$  prime  $n$ , we must know the normal component of that. You know both the velocity particles. What is this one? So,  $V_1$  prime  $n$ . Then similarly, tangential components are also unknown. So,  $V_1$  prime  $t$  and then  $V_2$  prime  $n$  and  $V_2$  prime  $t$ . Thus, you need four equations to solve that. From where will we get four equations?

What will you do to get four equations? There is no problem in solving this one; therefore, problem is solved. We just need four equations to find out unknowns. What are those unknowns normal after the impact, because before the impact we must know the velocities. Before the impact everything is known; masses are known, impacting velocities are known, at which angle they are going to make a contact is also known, because you know that you can join the line of contact and you can find out that angle also.

After the impact we must know the velocity. So, velocity has two components. Therefore, two particles. So, total four components, so four unknowns are there, or we can say  $V_1$  prime  $V_2$  prime and  $\theta_1$  prime and  $\theta_2$  prime are the unknown. So, we have to get four equations. Now, first equation we get, momentum of the system in the  $n$  direction gives  $m_1 V_1 n$  plus  $m_2 V_2 n$  is equal to  $m_1 V_1$  prime  $n$  plus  $m_2 V_2$  prime  $n$ . So, that means, in  $n$  direction the momentum

conserved and that is what that you are getting. This is one equation, because there they are impacting and the forces are applied normal to this one. Although the forces are applied normal, their velocities in the normal direction will change. However, that a total net momentum is conserved and you get this equation. So, this is one equation. How will you get the other equations?

(Refer Slide Time: 49:20)

**(2) and (3) The momentum for each particle is conserved in the  $t$ -direction since there is no impulse on either particle in the  $t$ -direction. Thus**

$$m_1(v_1)_t = m_1(v'_1)_t \quad m_2(v_2)_t = m_2(v'_2)_t$$

**(4) The coefficient of restitution, as in the case of direct central impact, is the positive ratio of the recovery impulse to the deformation impulse. Hence, like in the case of direct impact,**

$$e = \frac{(v'_2)_n - (v'_1)_n}{(v_1)_n - (v_2)_n}$$

**Once four final velocity components are found, the angles  $\theta'_1$  and  $\theta'_2$  of the figure may be easily determined.**

In the second and third equations we get from this consideration, if there is a smooth contact then the momentum of each particle is conserved in the  $t$  direction. Otherwise also, you know that if the particles are making contact, then the momentum. When there is no impulse on either of the particles in the  $t$  direction, like smooth contact, then in that case  $m_1 V_{1t}$  is equal to  $m_1 V'_{1t}$ ; that means no tangential velocity change occurs for particle, a. Same thing is for particle b, means another particle also; that is  $m_2 V_{2t}$  is equal to  $m_2 V'_{2t}$ . So,  $V_{2t}$  is equal to  $V'_{2t}$ , these are the conditions.

Otherwise, if friction is there, then the situation becomes difficult. Another condition, fourth condition is the coefficient of restitution as in the case of direct central impact. It is to be noted that the coefficient of restitution is defined as the ratio of the velocity of separation to velocity of approach. These velocities are always normal, not the tangential velocity. So, we define with

respect to that normal velocity. So, the coefficient of restitution as in the case of direct central impact is the positive ratio of the recovery impulse to the deformation impulse.

Hence, like in the case of direct impact, we get here also  $e$  is equal to  $V_2' \cdot n - V_1' \cdot n$  divided by  $V_1 \cdot n - V_2 \cdot n$ . So, this is the thing normal. We have got now four equations, one is in terms of normal momentum it means conserved. Then for two particles, separately we have written that tangential this thing. If friction is known, then we have to know that friction force etc., and by that we will find out the change in velocity. But here, in the smooth contact you can easily find out and fourth equation is given by this one. So, four velocity components are found. Then, if you can find out four final velocity components, then we can determine angles  $\theta_1'$  and  $\theta_2'$  and our problem is solved. So, this method can be implied.

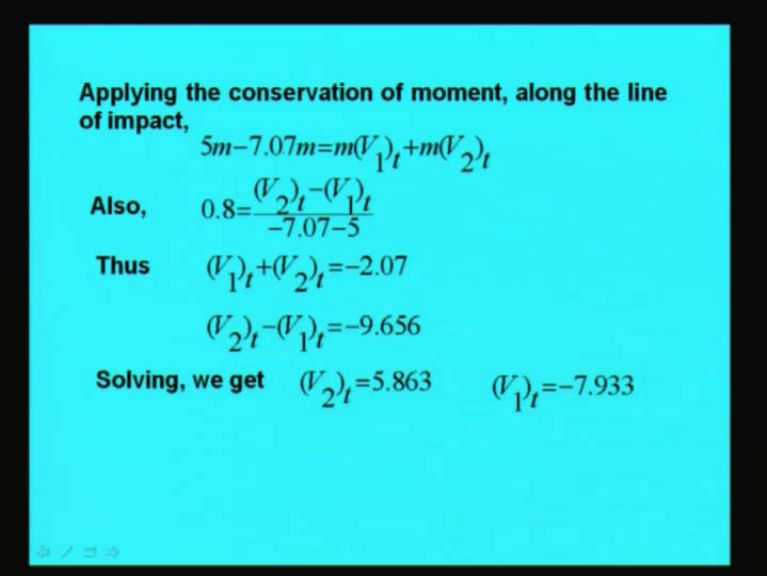

(Refer Slide Time: 52:02)

I give one example of oblique contact. Supposing, two balls of the same size and mass collide with the velocities of approach shown. Two balls of same size are colliding with the velocity shown for a coefficient of restitution of 0.8. What are the final velocities after they part? That question is there. So, what happens? That body, one body is going with 5 meter per second, other body is coming at 10 meter per second this is 10 meter per second but this velocity is at 45 degree to the common normal. In that case, resolve it into two components.

So, one component that normal component is 7.7, 7.07 and this is 1 meter per second, normal component is also 7.07 meter per second like that.

(Refer Slide Time: 53:14)

Applying the conservation of moment, along the line of impact,

$$5m - 7.07m = m(V_1)_t + m(V_2)_t$$

Also,

$$0.8 = \frac{(V_2)_t - (V_1)_t}{-7.07 - 5}$$

Thus

$$(V_1)_t + (V_2)_t = -2.07$$

$$(V_2)_t - (V_1)_t = -9.656$$

Solving, we get

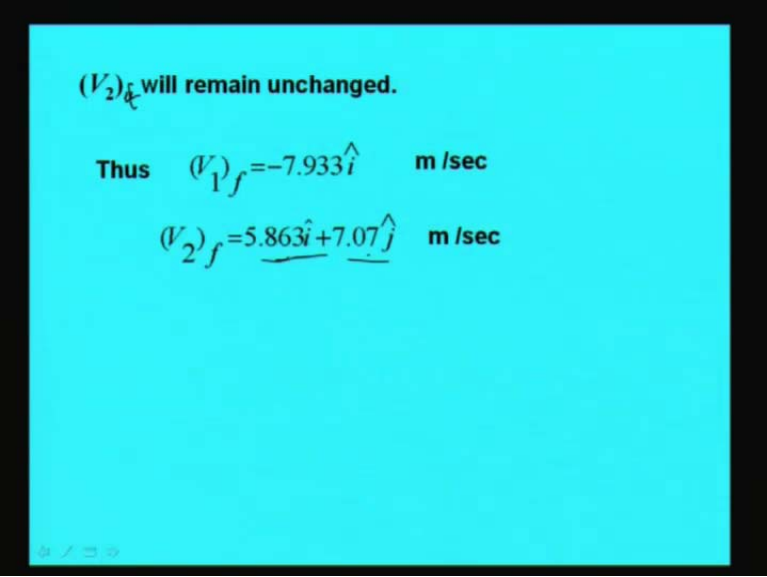

$$(V_2)_t = 5.863 \quad (V_1)_t = -7.933$$

Then, you apply the conservation of momentum along the line of impact. So, 5 into mass, if mass is same. So, 5m minus 7.07m. In the beginning this velocity, this velocity is in opposite direction, so minus sign and is equal to  $m_1 V_{1t}$  plus  $m_2 V_{2t}$  normal, that is along the normal directions. Let us use the symbol n here. Also we have, coefficient of restitution is 0.8 given.

Therefore, 0.8 is equal to  $V_{2n}$  minus  $V_{1n}$  and divided by, in the beginning, minus 7.07 because this is minus 7.07 and the other is a minus 5; because these are minus 5, so velocity of approach. They are approaching towards each other with 7.07 plus 5, so it gets added. So therefore, we have this is  $V_{2n}$  minus  $V_{1n}$  plus  $V_{2n}$  is equal to, from the first moment conservation equation. This is actually momentum minus 2.07. Similarly, here you get  $V_{2n}$  and  $V_{1n}$  is equal to minus 9.656. Solving this, we get  $V_{2n}$  is equal to 5.863 and  $V_{1n}$  is equal to minus 7.933.

(Refer Slide Time: 55:10)

$(V_2)_t$  will remain unchanged.

Thus  $(V_1)_f = -7.933 \hat{i} \text{ m/sec}$

$(V_2)_f = \underline{5.863 \hat{i}} + \underline{7.07 \hat{j}} \text{ m/sec}$

We have obtained like that.  $V_{2t}$ ,  $V_{1t}$  n  $V_{2t}$  remains same. Therefore, final velocity of that one particle can be written as minus 7.933 i in the i direction and the other one is actually 5.863 i plus 7.07 j in that direction, because you know that 7.07 components remains unchanged and only this part we have added in the i direction. So, this is what the velocity. By solving the four equations, we have been able to solve this problem. So, these are the basic concepts about the direct and central impact. Now, let me just tell you simple things and simple problems.

(Refer Slide Time: 56:36)

$$\begin{aligned}
 e &= 0 \\
 V_2' - V_1' &= 0 \\
 mV_1 + mV_2 &= mV_0 + mV_0 \\
 V_0 &= \frac{V_1 + V_2}{2} \\
 \frac{1}{2}mV_1^2 + \frac{1}{2}mV_2^2 &= (KE)_i \\
 \frac{1}{2}mV_0^2 + \frac{1}{2}mV_0^2 &= (KE)_f \\
 \frac{1}{2}m[V_1^2 + V_2^2 - 2V_0^2] & \\
 &= \frac{1}{2}m[V_1^2 + V_2^2 - 2\left(\frac{V_1 + V_2}{2}\right)^2] \\
 &= \frac{1}{2}m[2V_1^2 + 2V_2^2 - V_1^2 - V_2^2 - 2V_1V_2] \\
 &= \frac{1}{2}m(V_1 - V_2)^2
 \end{aligned}$$

We discussed some problems, like suppose you want to show, in the case of the contact of two bodies with which a perfectly plastic impact  $e$  is equal to 0. In that case,  $V_2$  prime minus  $V_1$  prime will be 0; that means, both moves with the same velocity. Therefore, what happens in this case, you get mass into that, suppose the two particles of this one, two particles are of the same mass, we have to just simplify the situation. I am taking the two particles of the same mass. In that case, it will be initially, the velocity may be  $mV_1$  plus  $mV_2$ . This is  $m$  and finally the velocities become  $V_0$ , same velocity.

This will become  $mV_0$  plus  $mV_0$ . All  $V_0$  then will become basically  $V_1$  plus  $V_2$  by 2. In the beginning, you are having the kinetic energy half  $m_1V_1$  square plus half  $m_2V_2$  square, but finally the kinetic energy has. So, this is  $KE_i$  and  $KE_{final}$  is half  $mV_0$  square plus half  $mV_0$  square, that means  $V_0$ . So, this is  $KE_{final}$ . So, what is the change in the kinetic energy is, that means half  $m$  is common. So, we can take half also common. So, basically we will get  $V_1$  square plus  $V_2$  square and then minus  $2V_0$  square; that is, initial minus final. So, half  $m$  will remain common and this will become  $V_1$  square plus  $V_2$  square minus twice  $V_1$  plus  $V_2$  whole square by 4. So, this will become half  $m$  and this will become  $V_1$  square. So, we can write that minus.

This will become  $V_1$  by this one. This will become something like this;  $V_1$  square plus  $V_2$  square minus or 2 we can take common, then this becomes  $2V_1$  square  $2V_2$  square minus  $V_1$  square

minus  $V_2$  square minus twice  $V_1 V_2$ . So, the inside quantity can be written as something outside, because then  $V_1$  minus  $V_2$  whole square. Therefore, this energy is always positive; that means, initial kinetic energy is always more than final kinetic energy.

(Refer Slide Time: 01:01: 10)

Similarly, I give one example of some oblique contact. Suppose there is a rigid floor and a ball is hitting here at  $\phi$  theta angle from normal, it gets reflected. If there is a perfect elastic collision, then in that case, it will get reflected at the same theta. Why because in that case, the velocity of approach and velocity of this one, magnitude should be same, therefore theta. However, in the other case, if you know that  $e$  is not equal to this one, then the velocity of separation should reduce and therefore, you know it will move at something like this.

Therefore, this angle may be something  $\phi$ , where  $\phi$  will be less than theta, say more than theta. In this case  $\phi$  will be more than theta. So, if a small ball hits that perfectly smooth rigid surface, in that case, just like a light gets reflected, in the same way it get reflected and otherwise this is the thing. So, this is one example of that oblique impact.
