**Method of momentum and analysis of robot manipulator**

In this lecture, we will discuss methods of momentum for bodies. We will also discuss one problem of robotic manipulator, where to develop the equation's dynamics finds an important role. We have already discussed the concept of momentum for a particle.

(Refer Slide Time: 01:36)

Linear momentum of a particle is mass times the velocity of the particle. Linear momentum of a mass system is the vector sum of the linear momentum of all its particles. If we denote this linear momentum by  $G$  and mass and velocity of the  $i^{\text{th}}$  particle by  $m_i$  and  $V_i$  respectively, then

$$G = \sum m_i V_i = \sum m_i \dot{r}_i$$

When the mass of each particle remains constant, the above expression may be written as

$$G = \frac{d(\sum m_i r_i)}{dt}$$

Linear momentum of a particle is mass times the velocity of the particle. It is the product of the mass and velocity. It is a function of mass and velocity; just a simple product. Linear momentum of a mass system is the vector sum of the linear momentum of all its particle. Because momentum is a vector and kinetic energy is scalar, we find out the

kinetic energy of this thing by summing kinetic energies of all the particles. Here also, we will do simple summation only. However that radial momentum is vector; therefore, it has to be summed in that way. If we denote the linear momentum by  $G$  and mass and velocity of the  $i$ th particle by  $m_i$  and  $V_i$  irrespectively, then  $G$  is equal to  $\sum m_i V_i$ . We get this for a system of particle and this is equal to  $\sum m_i \dot{r}_i$ , where  $r_i$  is the position vector of the particle.

When the mass of each particle remains constant, this expression may be written like this.  $G$  is equal to  $\frac{d}{dt} \sum m_i r_i$  divided by  $dt$ ;  $\frac{d}{dt} \sum m_i r_i$ . So,  $m_i$  can come outside and it becomes the same previous expression.

(Refer Slide Time: 03:13)

**If  $r_G$  is the position vector of mass center and  $m$  is the total mass, then**

$$mr_G = \sum m_i r_i$$

**Thus**

$$G = \frac{d(mr_G)}{dt} = m\dot{r}_G = mV_G$$

**where,  $V_G$  is the velocity of the mass center.**

**This is true for rigid as well as non rigid body. Differentiating the above expression with respect to the time**

If  $r_G$  is the position vector of mass center and  $m$  is the total mass, then  $m$  times  $r_G$  is equal to  $\sum m_i r_i$ . Thus, we have  $\frac{d}{dt} (mr_G)$  is equal to  $m\dot{r}_G$ , which is equal to  $mV_G$ , where  $V_G$  is the velocity of the mass center of the particles. There may be finite number of particles or infinite number of particles making the body or it can be system of mass. So, we get the equation that momentum of a system of particles is basically nothing but the mass times the velocity of the mass center. It is true for rigid as well as non rigid body. Here, we are not making any assumption that the particles cannot come towards each other. Therefore, this equation is valid for rigid as well as non rigid body.

(Refer Slide Time: 04:27)

$$\dot{G} = m\dot{V}_G = ma = \sum F = F_{\text{net}}$$
$$\sum F = \dot{G}$$

Integrating the above relation between  $t_1$  and  $t_2$ ,

$$\int_{t_1}^{t_2} F_{\text{net}} dt = G_2 - G_1$$

Note that all external forces exert impulses, whether they do work or not.

If we differentiate this expression with respect to time, then we get  $\dot{G}$  is equal to  $m\dot{V}$ .  $\dot{G}$  is equal to  $ma$ ,  $a$  is the acceleration of the mass center. This will become  $\sum F$  and that will become  $F_{\text{net}}$ . So,  $\sum F$  is equal to  $\dot{G}$ . We get one relation that  $\sum F$  is equal to  $\dot{G}$ . If we integrate the above relation between  $t_1$  and  $t_2$ , then  $\int_{t_1}^{t_2} F_{\text{net}} dt$  is equal to  $G_2$  minus  $G_1$ . This is the impulse of the total. Note that, all external forces exert impulses whether they do work or not. So all the forces have to be considered in this case. Then you can find out  $G_2$  minus  $G_1$ . So, this equation can also be used. This is about linear momentum.

(Refer Slide Time: 05:26)

**Angular Momentum:**

**Angular momentum is defined as the moment of linear momentum.**

**For a system of particles, the angular momentum  $H_G$  (about the mass center) is given by**

$$H_G = \sum \rho_i \times m_i V_i$$

**where  $\rho_i$  is the position vector of the particle about the center of mass as shown in the figure.**

Now, we discuss about the angular momentum. Angular momentum is defined as the moment of linear momentum. For a system of particles the angular momentum  $H_G$  about the mass center is given by  $H_G$  is equal to sigma  $\rho_i$  cross  $m_i V_i$ , where  $\rho_i$  is the position vector of the particle about the center of mass and  $V_i$  may be the absolute velocity of this.

(Refer Slide Time: 06:02)

For example, this is the situation. You have body. This is the axis system; G is the mass center and it is rotating with angular velocity  $\omega$ , and  $\rho_i$  is the distance of the mass from this and this is  $r_i$  and this is  $r_G$ . We have the absolute velocity term here  $m_i V_i$ , but  $\rho_i$  is the position vector of the particle about the center of the mass. Then you have  $V_i$ ; that means, velocity of the particle is  $\dot{r}_i$  is equal to  $\dot{\rho}_i$  plus  $\dot{r}_G$ .

(Refer Slide Time: 06:41)

Hence,

$$\begin{aligned}H_G &= \sum \rho_i \times m_i (\dot{\rho}_i + \dot{r}_G) \\&= \sum m_i \rho_i \times \dot{r}_G + \sum m_i \rho_i \times \dot{\rho}_i\end{aligned}$$

As **G** is the mass center, the first term in the above expression is 0. Hence,

$$H_G = \sum m_i \rho_i \times \dot{\rho}_i$$

Hence,  $H_G$  is equal to  $\sum \rho_i \times m_i \dot{\rho}_i + r \times \dot{r}_G$  and this will become  $\sum m_i \rho_i \times \dot{r}_G + \sum m_i \rho_i \times \dot{\rho}_i$ . As in this case, G is the mass center. So, the first term in this expression is 0 because  $\sum m_i \rho_i$ , if you will do the summation that will be total mass times the distance of center of mass from that point. So, it is 0 and this portion goes to 0. Therefore,  $H_G$  is equal to  $\sum m_i \rho_i \times \dot{\rho}_i$ .

(Refer Slide Time: 07:38)

**For a rigid body,**

$$\dot{\rho}_i = \omega \times \rho_i$$

**For a body in plane motion,**

$$H_G = \sum \rho_i^2 m_i \omega \hat{k} = I \omega \hat{k}$$

**Where,**

$$I_G = \sum m_i \rho_i^2$$

**Thus,**

$$H_G = I_G \omega$$

Now, for a rigid body  $\rho_i \dot{\theta}$  is equal to  $\omega$  cross  $\rho_i$ ;  $\rho_i$  is the distance of the particle from the mass center. If we differentiate it, magnitude remains same, only rotation is there. So, therefore we get  $\omega$  plus  $\rho_i$ . For a body in plane motion, this simply becomes  $H_G$  is equal to  $\rho_i^2 m_i \omega \hat{k}$  that means this is basically  $I$   $\omega$  into  $\hat{k}$ .  $I$  is the mass moment of inertia of the whole thing because  $H_G$  is equal to  $\sum m_i \rho_i^2$ . In plane motion, it is having only angular velocity  $\omega \hat{k}$ . We will get,  $I_G \omega$  in that  $\hat{k}$  direction and this is what has come.

(Refer Slide Time: 08:55)

Now,

$$\boxed{\sum M_G = \dot{H}_G}$$

Hence,

$$\int_{t_1}^{t_2} M_G dt = H_{G_2} - H_{G_1}$$

Angular momentum about any general point **O** is

$I_G$  is equal to basically  $\sum m_i r_i^2$  and that I can write  $I_G$ . This is  $I_G$ . Therefore,  $H_G$  is equal to  $I_G \omega$  is the expression we get in this one.  $\sum M_G$  is equal to  $\dot{H}_G$ ; that we already have. Hence, if we take  $t_1$  to  $t_2$   $M_G dt$  is equal to  $H_{G_2}$  minus  $H_{G_1}$ . If we can find out impulse of the moments then that is change into the angular momentum.

(Refer Slide Time: 09:11)

$$\begin{aligned} H_O &= \sum r_i \times m_i V_i \\ &= \sum (r_G + \rho_i) \times m_i V_i \\ &= \sum (r_G + \rho_i) \times m_i (\dot{\rho}_i + \dot{r}_G) \\ &= \sum r_G \times m_i (\dot{\rho}_i + \dot{r}_G) + \sum \rho_i \times m_i (\dot{\rho}_i + \dot{r}_G) \\ &= \sum r_G \times m_i \dot{\rho}_i + \sum r_G \times m_i \dot{r}_G + \sum \rho_i \times m_i \dot{\rho}_i + \sum \rho_i \times m_i \dot{r}_G \end{aligned}$$

$\downarrow$   
**O**

As **G** is the mass center, the first and last terms in the above expression will be zero. Hence,

We have discussed angular momentum about the center of mass. Let us discuss angular momentum about any general point **O** that is  $H_O$  is equal to  $\sum r_i \times m_i V_i$  that is

$\sum \mathbf{r}_G \times \rho_i \times m_i \mathbf{V}_i$ . This can be written as  $\sum \mathbf{r}_G \times \rho_i \times m_i \dot{\mathbf{r}}_i$  plus  $\mathbf{r} \cdot \mathbf{G}$  and that becomes  $\sum \mathbf{r}_G \times m_i \dot{\mathbf{r}}_i$  plus  $\mathbf{r} \cdot \mathbf{G}$  plus  $\sum \rho_i \times m_i \dot{\mathbf{r}}_i$  plus  $\mathbf{r} \cdot \mathbf{G}$  and this is equal to  $\sum \mathbf{r}_G \times m_i \dot{\mathbf{r}}_i$  plus  $\sum \mathbf{r}_G \times m_i \mathbf{r} \cdot \mathbf{G}$  plus  $\sum \rho_i \times m_i \dot{\mathbf{r}}_i$  plus  $\sum \rho_i \times m_i \mathbf{r} \cdot \mathbf{G}$ . As  $\mathbf{G}$  is the mass center, the first and last term in the above expression will be 0.  $\mathbf{r}_G$  is a constant;  $\mathbf{r}_G \times m_i \dot{\mathbf{r}}_i$  is 0, because it is about the mass center we are taking the rate of moment of mass. You take the moment of mass and then differentiate it, so this term becomes 0 and last term also is this one;  $\sum \rho_i \times m_i$  and  $m_i \rho_i \sum$  and this term will become 0. In this case,  $m_i \rho_i$  is equal to 0. So, therefore this term also vanishes.

(Refer Slide Time: 11:39)

Hence, you have got  $H_0$  is equal to  $\sum \mathbf{r}_G \times m_i \mathbf{r} \cdot \mathbf{G}$  plus  $\sum \rho_i \times m_i \dot{\rho}_i$  and this will be equal to  $mV_G d \hat{k}$ , we can write. How does this come?  $\mathbf{r} \cdot \mathbf{G}$  is  $\mathbf{V}_G$  and this is the cross product of  $\mathbf{r}_G$  into  $\mathbf{V}_G$ . Therefore, if the perpendicular distance is  $d$ , so  $mV_G$  into  $d \hat{k}$  and plus  $I \omega$  into  $\rho_i \times m_i$  is  $I \omega \hat{k}$  and  $d$  is the length of the perpendicular drawn from zero to a line passing through  $G$  in the direction of  $\mathbf{V}_G$ . This is what we get.  $H_0$  is equal to  $mV_G$  in a plane **that is this one** and  $I \omega$  into  $\hat{k}$ , for a plane motion.

(Refer Slide Time: 12:55)

$$H_0 = I_G \omega + m V_G d$$

When a body rotates about a fixed point O on the body or body extended. The relations  $V_G = r_G \omega$  and  $d = r_G$  may be substituted into the expression for  $H_0$ , giving

$$H_0 = I_G \omega + m r_G^2 \omega$$

But,

$$I_G + m r_G^2 = I_0$$

So,

$$H_0 = I_0 \omega$$

Therefore, we can write  $H_0$  is equal to  $I_G$  omega plus  $m V_G$  into  $d$ . When a body rotates about a fixed point O on the body or body extended, the relations  $V_G$  is equal to  $r_G$  omega and  $d$  is equal to  $r_G$  may be substituted into the expression for  $H_0$ , giving  $H_0$  is equal to  $I_G$  omega plus  $m r_G$  square into omega. But  $I_G$  plus  $m r_G$  square is equal to  $I_0$ , therefore  $H_0$  is equal to  $I_0$  omega. So, we get  $H_0$  is equal to  $I_0$  omega.

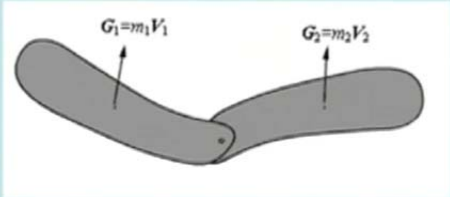

(Refer Slide Time: 13:41)

$$\sum M_0 = I_0 \dot{\omega}$$

Or,

$$\int_{t_1}^{t_2} \sum M_0 dt = I_0 (\omega_2 - \omega_1)$$

**Interconnected rigid bodies**

We also have  $\sum M_0$  is  $I_0 \dot{\omega}$ . So, therefore  $t_1$  to  $t_2$   $\sum M_0 dt$  is equal to  $I_0 \omega_2$  minus  $\omega_1$ .

Now, we discuss about interconnected rigid bodies. Suppose two bodies are interconnected, then the linear momentum of one body can be written as  $G_1$  is equal to  $m_1 V_1$  and another body  $G_2$  is equal to  $m_2 V_2$ . These may be the two links.

(Refer Slide Time: 14:26)

**If two bodies are interconnected, there combined free body diagram can be made. If  $\sum F$  is the net external force on the bodies**

$$\sum F = \dot{G}_1 + \dot{G}_2 = \dot{G}_{\text{system}}$$

**If  $\sum M_0$  is the net moment on the bodies about point O, then**

$$\sum M_0 = \dot{H}_{o_1} + \dot{H}_{o_2} = \dot{H}_{o_{\text{system}}}$$

If two bodies are interconnected their combined free body diagram can be made. If  $\sum F$  is the net external force on the bodies then  $\sum F$  is equal to  $G_1$  dot plus  $G_2$  dot is equal to  $G$  dot system. If  $\sum M_0$  is the net moment on the bodies about point O, then  $\sum M_0$  is equal to  $H$  dot  $o_1$  plus  $H$  dot  $o_2$  is equal to  $H$  dot o system.

(Refer Slide Time: 15:03)

Thus,  $\int_{t_1}^{t_2} F dt = \Delta G_{\text{system}}$

and  $\int_{t_1}^{t_2} M dt = \Delta H_{\text{system}}$

**Conservation of momentum**

$$\sum F = 0$$

means  $\Delta G = 0$

Similarly,  $t_1$  to  $t_2$   $F dt$  is equal to  $\Delta G_{\text{system}}$  and similarly, we can have  $t_1$  to  $t_2$   $M dt$  is equal to  $\Delta H_{\text{system}}$ ; combined for system, we can write. Conservation of momentum applies here also, if the net external force  $\sum F$  is zero. This means that  $\Delta G$  is equal to 0, combined linear momentum ..... of the bodies or links connected together remains conserved although their individual momentums may change.

(Refer Slide Time: 15:51)

Thus, if the net external force on the body is zero, its linear momentum remains conserved.

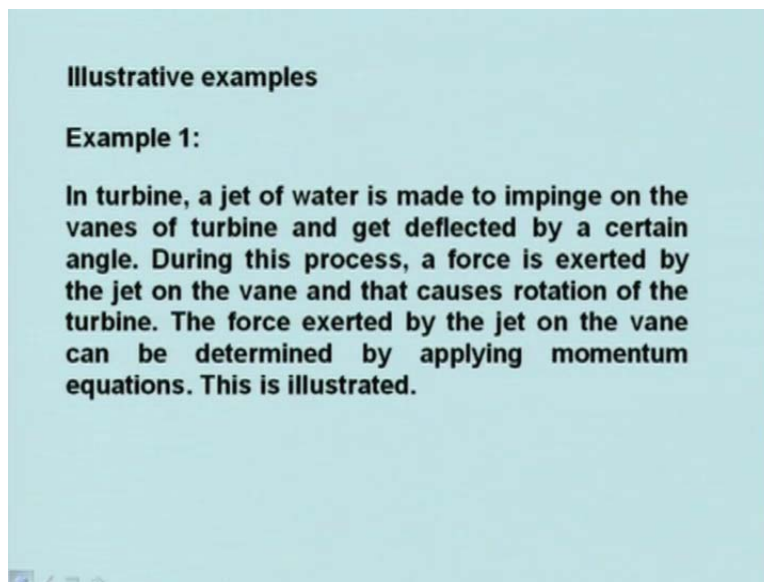

Similarly, if resultant moment <sup>of the  $\vec{r} \times \vec{v}$</sup>  about a point is zero, the angular momentum <sup>^</sup> about O remains conserved.

$$\Delta H_0 = 0$$

In this case the angular momentum about G remains constant.

So, combined linear momentum is this one. Thus, if the net external force on the body is zero, its linear momentum remains conserved. Similarly, if resultant moment about a point is zero, the angular momentum about O remains conserved. That is, if the resultant moment of the forces about a point is 0, then the angular momentum about O remains conserved. In this case, the angular momentum about G remains constant. So, that is what you get.

(Refer Slide Time: 16:38)

We give some examples; let us take one example of these principles. Now, let us see, one example from turbine.

(Refer Slide Time: 16:53)

This is a turbine bucket. Suppose, in the beginning it is stationary. You have jet of water impinging with velocity  $V_0$  and it gets deflected. The velocity remains unchanged but it gets deflected at theta, and here also, it gets deflected to theta. Then, in that case, this will be like this. In a turbine, jet of water is made to impinge on the vanes of turbine and get deflected by a certain angle. During this process, a force is exerted by the jet on the vane and that causes a rotation of the turbine. The force exerted by the jet on the vane can be determined by applying momentum equations. Now this can be done like this.

(Refer Slide Time: 17:59)

$(\rho QA)$   ~~$\rho Q$~~   $\rho VA$

**Applying impulse momentum equation**

$$F_x = (\cancel{\rho Q A})(-V_0 + V \cos \theta)$$

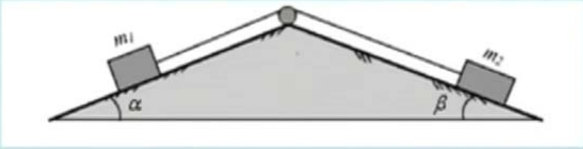

**The water exerts equal and opposite force on the blade.**

$\rho QA$  is the rate of mass coming on that;  $Q$  is the discharge,  $A$  is the area and  $\rho$  is this one. We can say  $Q$  or it should be  $\rho$  times  $V_A$ . Then applying momentum equation in this equation, we have  $\rho Q$  and this is minus  $V_0$  and plus  $V \cos \theta$ , that is the change in the momentum. So,  $V \cos \theta$  minus  $V_0$ , that is  $F_x$ . So, water exerts equal and opposite force on the blade. There is no net vertical force in this problem because of symmetry.

(Refer Slide Time: 18:57)

**There is no net vertical force in this problem. This is because of symmetry.**

**Example 2:**

The diagram shows a symmetric wedge with two inclined planes. The left plane is at an angle  $\alpha$  and the right plane is at an angle  $\beta$ . A block of mass  $m_1$  is on the left plane, and a block of mass  $m_2$  is on the right plane. The wedge is supported by a central vertical axis, and the entire system is symmetric about this axis.

Now example 2 of interconnected bodies, suppose two bodies are acting here. This is  $M_1$  and this is  $M_2$  and they are put on the inclined plane. This is  $\alpha$  and this is  $\beta$ , angle inclined with this.

(Refer Slide Time: 19:20)

The blocks of mass  $m_1$  and  $m_2$  have on the smooth inclined planes. If they are at rest initially, find out the speed of the blocks after time  $t$ . Let  $T$  be the tension in the string,  $V$  the final speed.

Applying impulse momentum equation to  $m_2$

$$(m_2 g \sin \beta - T)t = m_2 V$$

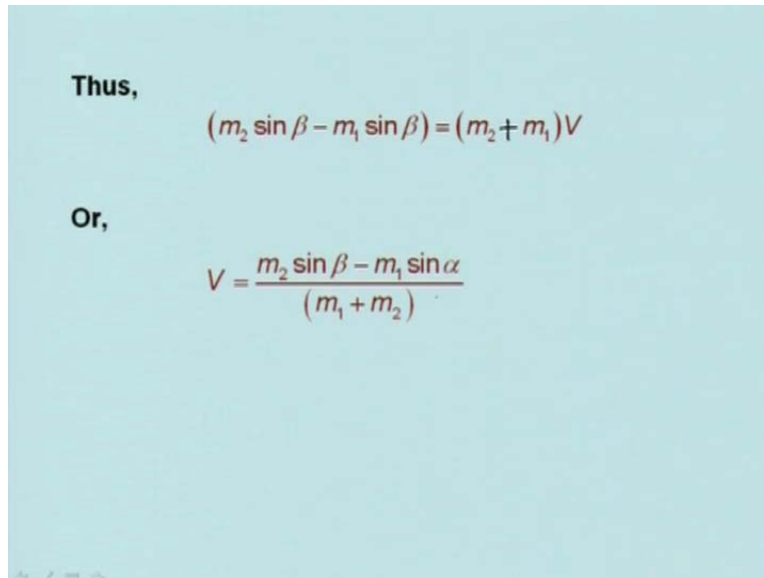

Similarly, applying, the impulse momentum equation to  $m_1$

$$(T - m_1 g \sin \alpha)t = m_1 V$$

The blocks of mass  $m_1$  and  $m_2$  have been kept on the smooth inclined plane. There are no forces acting, external forces. If they are at rest initially, find out the speed of the blocks after time  $t$ . Let  $T$  be the tension in the string and  $V$  the final speed. So, applying impulse momentum equation to  $m_2$ , we have  $m_2 g \sin \beta$  minus  $T$  into  $t$  is equal to  $m_2 V$ . We have to consider this tension  $T$  also. Similarly, apply the impulse momentum equation to  $m_1$ ,  $T$  minus  $m_1 g \sin \alpha$   $t$  is equal to  $m_1 V$ .

(Refer Slide Time: 20:13)

Thus,

$$(m_2 \sin \beta - m_1 \sin \beta) = (m_2 + m_1)V$$

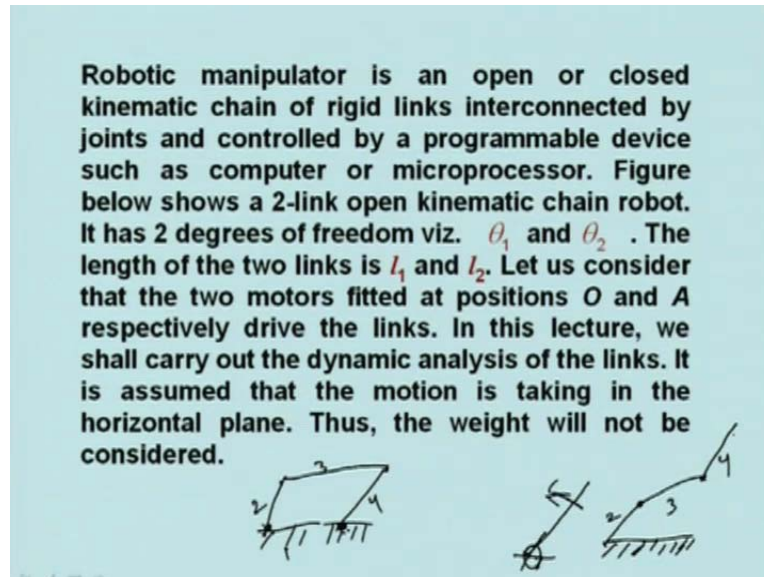

Or,

$$V = \frac{m_2 \sin \beta - m_1 \sin \alpha}{(m_1 + m_2)}$$

Then what we can do, we can add these two equations. So, we get  $m_2 \sin \beta$  minus  $m_1 \sin \beta$  is equal to  $m_2$  plus  $m_1$  into  $V$  or we get  $V$  is equal to  $m_2 \sin \beta$  minus  $m_1 \sin \alpha$  divided by  $m_1$  plus  $m_2$ .

This is how we have found out that the velocity of particle of masses  $m_1$  and  $m_2$ , by applying the impulse momentum. Impulse momentum equation has provided us this. We have discussed about the kinetics of bodies and mostly, we have given the examples from the rigid motion of the bodies.

(Refer Slide Time: 21:06)

Now, most of the things we have taken are the simple examples so that you can easily solve them with hand calculations and may be with the help of calculator. But actually, the application of dynamics is very broad and you may have to do number of problems. In that, even hand calculations will not be sufficient. One may have to use computer for solving the equations and there are these things. By now, you must know how to develop the equations, for you know dynamic this one.

I have taken one example the dynamic analysis of a two link rigid robotic manipulator. There are two links which are moving on a plane. So, it contains number of very big equation. I am not going to discuss about the solution, but we will form the equations. What is a robotic manipulator? Robot consists of mostly the links. Suppose this simple link may be there.

(Refer Slide Time: 22:42)

This may be some link. It rotates; when you give command it rotates. This is one link of a robot. In general, a robotic manipulator can consist of number of links. So, it may likely have kinematic chain. That is called four bar mechanism. Here, this link is fixed, another link connected by pin joint, another like this and then this is like this. This is 1,2,3,4. So, this is a four bar mechanism and you see that this chain is closed. This is a chain of links, link 1,2,3,4. Link 1 starts at one point and link 4 closes at that point. This is called closed kinematic chain and its degree of freedom is 1; that means, if we give some rotation to 2, then we can know that how much that 4 will move.

We can have open kinematic chain also. Suppose one link was fixed, but I could have connected to 2 and this becomes 3 and this becomes 4. So this is 2,3,4. In that case, it is an open kinematic, but in robots, these types of things are quite often used. This is link number 2, this is 3, this is 4 and they will have independent motion. I can put a motor, here I can put a motor here; I can put a motor at link number 3. So, this is what can be done. This has got three degrees of freedom, because three independent motions are possible. This is open kinematic chain. So, robotic manipulator is an open or closed kinematic chain of rigid links. Generally, we consider the links to be rigid. Otherwise, flexibility can also be considered; interconnected by joints and controlled by a

programmable device, such as computer or microprocessor. This is just linkage; but in robotic manipulator this will be generally controlled by programmable device such as any computer or microprocessor.

We take example of just two link robotic manipulator. Only two links are there. This is open kinematic chain and it has got two degrees of freedom. You see that even this will give us complicated equations; one link is simple case. So, here, that link 1 is of length  $l_1$  and this angle is  $\theta_1$  and it is pivoted about point O. It can rotate. One motor is put and link 2 is about this one. This is  $\theta_2$  and this is about this one  $X_1$  and this is  $Y_2$  and this is  $l_2$ . So, this becomes like this one  $X_1$   $Y_1$   $\theta_2$   $l_1$   $l_2$ . Then the length of the two links is  $l_1$  and  $l_2$ . Let us consider the two motors fitted at position O and A respectively, driving the links. O and A are driving the links.

In this lecture, we shall carry out the dynamic analysis of the links. It is assumed that the motion is taking in the horizontal plane. Then we will not have to consider weight. So, motion is just taking place in the horizontal plane; that means there is a motor fitted at O and there is a motor on A also, which is driving this thing. So, that way it can be done.

(Refer Slide Time: 27:14)

**Let us make the free-body diagram of link 2. This link is subjected to a torque, which is supplied by the joint motor at A. Also, the joint reactions act on the link, 2 components of which have been shown at A.**

We can make the free body diagram of link 2. Now, this is the link 2. Here, I have shown the axis system also. One fixed axis is like this, X and Y here. Then you have  $X_1$   $Y_1$  that is  $X_1$  is along the link 1 and  $Y_1$  is perpendicular to that one. So it is a moveable coordinate system that is attached at point 1 and similarly  $X_2$   $Y_2$  is like this; that along this and this is this thing.

Now, make the free body diagram of link 2. This link is subjected to torque which is supplied by the joint motor at A. The joint reactions act on the link. We have shown that some effects on  $F_y$  component, but you know that effects 2 and  $Y_2$ , but we are not going to determine this. It is not necessary to determine the joint reactions, but I have shown here. Also the joint reactions act on the link. Therefore, joint reactions are also there and they have been shown just like this.

(Refer Slide Time: 28:51)

**Tangential acceleration of any particle  $P$  with respect to  $A = x(\ddot{\theta}_1 + \ddot{\theta}_2)\hat{j}_2$  where  $\hat{j}_2$  is the unit vector along  $x_2$  and acceleration of**

$$A = a_A$$

$$= l_1 \ddot{\theta}_1 \hat{j}_1 - l_1 (\dot{\theta}_1)^2 \hat{i}_1$$

**where the unit vectors  $\hat{i}_1$  and  $\hat{j}_1$  are in the direction of  $X_1$  and  $Y_1$  respectively.**

**Resolved component of this acceleration along the normal to the axis of second link :**

$$(l_1 \ddot{\theta}_1 \cos \theta_2 + l_1 (\dot{\theta}_1)^2 \sin \theta_2) \hat{j}_2$$

Here, tangential acceleration of any particle P with respect to A is  $x$   $\theta_{11}$  dot dot plus  $\theta_{22}$  dot dot  $j_2$ , where  $j_2$  is the unit vector along  $x_2$ . Acceleration of A is basically given that is  $a_A$  that is  $l_1 \theta_{11}$  dot dot  $j_1$  that is tangential acceleration minus  $l_1 \theta_{11}$  dot dot  $i_1$  that is centripetal acceleration, where the unit vectors  $i_1$  and  $j_1$  are in the direction of  $X_1$  and  $Y_1$  respectively. Resolved component of this acceleration along the

normal to the axis of the second link are like this; you resolve these components  $l_1 \ddot{\theta}_1 \cos \theta_2$  plus  $l_1 \dot{\theta}_1^2 \sin \theta_2$  into  $j_2$ . You get like this. So, you have obtained the resolved component along normal to the axis **because that will be.**

(Refer Slide Time: 30:15)

**Therefore absolute tangential acceleration of particle**

$$P = x(\ddot{\theta}_1 + \ddot{\theta}_2) + (l_1 \ddot{\theta}_1 \cos \theta_2 + l_1 \dot{\theta}_1^2 \sin \theta_2)$$

**Force on this particle along  $Y_2$  direction**

$$m_2 \left[ x(\ddot{\theta}_1 + \ddot{\theta}_2) + l_1 \ddot{\theta}_1 \cos \theta_2 + l_1 \dot{\theta}_1^2 \sin \theta_2 \right] dx$$

**And the moment of this force about A**

$$m_2 \left[ x^2 (\ddot{\theta}_1 + \ddot{\theta}_2) + x l_1 \ddot{\theta}_1 \cos \theta_2 + x l_1 \dot{\theta}_1^2 \sin \theta_2 \right] dx$$

Therefore, absolute tangential acceleration of particle becomes  $x \ddot{\theta}_1 + \ddot{\theta}_2$  plus  $l_1 \ddot{\theta}_1 \cos \theta_2$  plus  $l_1 \dot{\theta}_1^2 \sin \theta_2$ . We have to do this because, Newton's law can be applied in inertial frame of reference and therefore, we have to talk about the absolute acceleration. Now, force on this particle along  $Y_2$  direction is this and one single particle  $m_2 x \ddot{\theta}_1 + \ddot{\theta}_2$  plus  $l_1 \ddot{\theta}_1 \cos \theta_2$  plus  $l_1 \dot{\theta}_1^2 \sin \theta_2$  into  $dx$ , because the mass of a small element at distance  $x$  is  $m_2$  into  $dx$ . So,  $m_2 dx$  is the small mass,  $m_2$  is the mass per unit length or it can be a function of per unit length, but it can still be a function of  $x$ . The moment of this force about A is basically you multiplied by  $x$  perpendicular distance. It becomes  $m_2 x^2 \ddot{\theta}_1 + \ddot{\theta}_2$  plus this will be  $l_1 x$  times this is  $x$  times  $l_1 \ddot{\theta}_1 \cos \theta_2$  dot plus  $x$  times  $l_1 \dot{\theta}_1^2 \sin \theta_2$  into  $dx$ .

(Refer Slide Time: 32:07)

Thus, the total torque  $T_2$  acting on  $A$ , through second joint motor is given by,

$$T_2 = \int_0^{l_2} m_2 \left[ x^2 (\ddot{\theta}_1 + \ddot{\theta}_2) + x l_1 \ddot{\theta}_1 \cos \theta_2 + x l_1 (\dot{\theta}_1)^2 \sin \theta_2 \right] dx$$

$$= \frac{m_2 l_2^3}{3} (\ddot{\theta}_1 + \ddot{\theta}_2) + \frac{m_2 l_1 l_2^2 \ddot{\theta}_1}{2} \cos \theta_2 + \frac{m_2 l_1 l_2^2}{2} (\dot{\theta}_1)^2 \sin \theta_2$$

Now, let us find out  $T_1$ . For this purpose, consider the free body diagram of two links together.

Thus, the total torque  $T_2$  acting on  $A$  through second joint motor is given by  $T_2$  is equal to  $m_2 \times \text{square } \theta_1 \text{ dot dot plus } \theta_2 \text{ square plus } x l_1 \theta_1 \text{ dot dot cos } \theta_2 \text{ plus } x l_1 \theta_1 \text{ dot square sin } \theta_2 dx$ . This we have to integrate from 0 to  $l_2$ . If we integrate this from 0 to  $l_2$ , we get by integrating  $m_2 l_2 \text{ square } l_2 \text{ cube by } 3 \text{ plus } \theta_1 \text{ dot dot plus } \theta_2 \text{ dot dot plus } m_2 l_1 l_2 \text{ square } \theta_1 \text{ double dot by } 2 \cos \theta_2$ . The third term is  $m_2 l_1 l_2 \text{ square by } 2 \theta_1 \text{ dot whole square sin } \theta_2$ . This is the expression for the torque coming on link 2. You see that this contains not only this term  $m_2 l_2 \text{ square}$ , but also it will depend on the other terms like acceleration of this and all these type of things. So we are getting these things. Here you are getting only the mass of link 2; you are not getting the mass of link 1.

Now, let us try to find out  $T_1$ , that means torque for link 1. For this purpose, consider the free body diagram of two links together.

(Refer Slide Time: 34:10)

We are considering the free body diagram of the links together. We could have drawn the free body diagram of only the link 1. In that case, the joint reactions will be coming at join A. Those are unknown to us, so we do not want to find out. That is why we are doing like this and in this case, you are showing that joint reactions  $F_{x1}$   $F_{y1}$  here and then torque  $T_1$  acting.

(Refer Slide Time: 34:58)

**For the particles on the first link**

**Tangential acceleration  $x\ddot{\theta}_1$**

$$dF = m_1 x \ddot{\theta}_1 dx$$

**where  $m_1$  is the mass per unit length of link 1.**

**The moment of this mass element about O is**

$$m_1 x^2 \ddot{\theta}_1 dx$$

**Thus the torque contributed by the particles of link 1**

What happens, when we consider it together, we have to consider not only the accelerations of link, 1 but you have to consider the accelerations of link 2 also. For the particles on the first link, tangential acceleration is  $\alpha$  times  $\theta_1$  dot dot and that is  $dF$  is equal to  $m_1 \times \theta_1$  dot dot  $dx$  where  $m$  is the mass per unit length of link 1. The moment of this mass element about O is  $m_1 \times x^2 \theta_1$  dot dot  $dx$ . Thus, the torque contributed by the particles of link 1 is basically  $T_1$  particles; 0 to  $l_1$ ,  $m_1 \times x^2 \theta_1$  dot dot  $dx$ .

(Refer Slide Time: 35:39)

$$T_1 = \int_0^{l_1} m_1 x^2 \ddot{\theta}_1 dx$$

$$= \frac{1}{3} m_1 l_1^3 \ddot{\theta}_1$$

If the total mass of link 1 is  $M_1$ , then

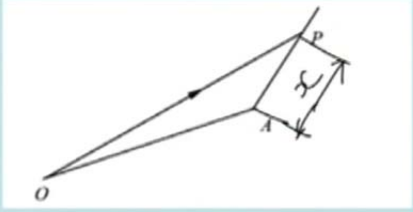

$$T_1 = \frac{M_1 l_1^2}{3} \ddot{\theta}_1$$

There will be requirement if torque for causing the motion of link 2 also.

If you integrate between 0 to  $l_1$ , you will get integration. If you put the limit,  $\frac{1}{3} m_1 l_1^3 \theta_1$  dot dot. If the total mass of link 1 is  $M_1$ , then  $T_1$  is equal to  $\frac{M_1 l_1^2}{3} \theta_1$  dot dot and this becomes  $\theta_1$  dot dot. So, this is a very nice expression that means, basically  $\theta_1$  dot dot is equal to  $\alpha$ . That means  $T$  is equal to  $\frac{1}{3} M_1 l_1^2 \alpha$ , had only the first link been present; other link was not there then matter was finished. Because this is the torque contributed by the particles of first link, motor will supply that torque. However there will be requirement of torque for causing the motion of link 2 also. That also has to be considered and that portion is little complicated to find out, but we will just discuss about that also.

(Refer Slide Time: 36:49)

Here, the coordinate of a point on link 2 is

$$\vec{OP} = l_1 \hat{i}_1 + x \cos \theta_2 \hat{i}_1 + x \sin \theta_2 \hat{j}_1$$

where  $\vec{x} = \vec{AP}$

Now, about the point O, the coordinate of point on link 2 is suppose P, so position vector OP is  $l_1 \hat{i}_1$  plus  $x \cos \theta_2 \hat{i}_1$  plus  $x \sin \theta_2 \hat{j}_1$ , where basically x is equal to AP. This is x. In this figure, this is x. We want to find out the position vector of point P that means position of point P with respect to O. So if we differentiate this position vector twice, we will get the absolute acceleration of point P. That is what we need.

(Refer Slide Time: 37:51)

The double differentiation of the position vector with respect to time provides,

$$\begin{aligned} \vec{a}_p = & l_1 \ddot{\theta}_1 \hat{j}_1 - l_1 (\dot{\theta}_1)^2 \hat{i}_1 - x (\ddot{\theta}_1 + \ddot{\theta}_2) \sin \theta_2 \hat{i}_1 \\ & + x (\ddot{\theta}_1 + \ddot{\theta}_2) \cos \theta_2 \hat{j}_1 \\ & - x (\dot{\theta}_1 + \dot{\theta}_2)^2 \cos \theta_2 \hat{i}_1 - x (\dot{\theta}_1 + \dot{\theta}_2)^2 \sin \theta_2 \hat{j}_1 \end{aligned}$$

We denote the torque at the joint O due to motion of the particles of link 2 by  $T_1^2$ .

Now, this is the expression we have got. We denote the torque at the joint O due to the motion of the particles of link 2 by  $T_1$  2.

$$T_1^2 = r \times F$$

$$= \int_0^{l_2} m_2 dx \left[ l_1^2 \ddot{\theta}_1 + l_1 x (\ddot{\theta}_1 + \ddot{\theta}_2) \cos \theta_2 - l_1 x (\dot{\theta}_1 + \dot{\theta}_2) \sin \theta_2 + l_1 x \cos \theta_2 \ddot{\theta}_1 \right]$$

$$+ x^2 (\ddot{\theta}_1 + \ddot{\theta}_2) \cos^2 \theta_2 - x^2 (\dot{\theta}_1 + \dot{\theta}_2)^2 \sin \theta_2 \cos \theta_2 + x l_1 (\dot{\theta}_1) \sin \theta_2$$

$$+ x^2 (\ddot{\theta}_1 + \ddot{\theta}_2) \sin^2 \theta_2 + x^2 (\dot{\theta}_1 + \dot{\theta}_2)^2 \sin \theta_2 \cos \theta_2,$$

$$= \int_0^{l_2} m_2 \left[ l_1^2 \ddot{\theta}_1 + l_1 x (\ddot{\theta}_1 + \ddot{\theta}_2) \cos \theta_2 - l_1 x \dot{\theta}_2^2 \sin \theta_2 - 2 l_1 x \dot{\theta}_1 \dot{\theta}_2 \sin \theta_2 \right. \\ \left. + l_1 x \cos \theta_2 \ddot{\theta}_1 + x^2 (\ddot{\theta}_1 + \ddot{\theta}_2) \right] dx$$

27

$\ddot{\theta}_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin^2 \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin \theta_2 \cos \theta_2$  which can be written as  $0$  to  $l_2$  this is  $m_2 l_1^2 \ddot{\theta}_1$  plus  $l_1 \cos \theta_1 \ddot{\theta}_2$  plus  $\ddot{\theta}_2 \cos \theta_2$  minus  $l_1 x \ddot{\theta}_2 \sin \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin^2 \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin \theta_2 \cos \theta_2$ . This is  $l_1 x \cos \theta_2 \ddot{\theta}_1$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin^2 \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin \theta_2 \cos \theta_2$ .

(Refer Slide Time: 42:01)

$$\begin{aligned}
 &= m_2 l_1^2 \ddot{\theta}_1 + \frac{m_2 l_1 l_2^2}{2} (\ddot{\theta}_1 + \ddot{\theta}_2) \cos \theta_2 - \frac{m_2 l_1 l_2^2}{2} \dot{\theta}_2^2 \sin \theta_2 \\
 &- 2 \frac{m_2 l_1 l_2^2}{2} \dot{\theta}_1 \dot{\theta}_2 \sin \theta_2 + \frac{m_2 l_1 l_2^2}{2} \cos \theta_2 \ddot{\theta}_1 + \frac{m_2 l_2^3}{3} (\ddot{\theta}_1 + \ddot{\theta}_2) \\
 &+ x^2 (\ddot{\theta}_1 + \ddot{\theta}_2) \cos^2 \theta_2 - x^2 (\dot{\theta}_1 + \dot{\theta}_2)^2 \sin \theta_2 \cos \theta_2 + x l_1 (\dot{\theta}_1) \sin \theta_2 \\
 &+ x^2 (\ddot{\theta}_1 + \ddot{\theta}_2) \sin^2 \theta_2 + x^2 (\dot{\theta}_1 + \dot{\theta}_2)^2 \sin \theta_2 \cos \theta_2
 \end{aligned}$$

Putting  $\underline{m_2 l_2 = M_2}$

$$\begin{aligned}
 T_i^2 &= M_2 l_1^2 \ddot{\theta}_1 + \frac{M_2 l_1^2}{3} \ddot{\theta}_2 + \frac{M_2 l_1 l_2}{2} \cos \theta_2 \ddot{\theta}_2 - \frac{M_2 l_1 l_2}{2} \dot{\theta}_2^2 \sin \theta_2 \\
 &- M_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin \theta_2
 \end{aligned}$$

Now, if we do the integration,  $0$  to  $l_2$ , particles are  $0$  to  $l_2$ , we get this expression  $M_2 l_1^2 \ddot{\theta}_1$  plus  $M_2 l_1 l_2^2$  square by  $2 \ddot{\theta}_1$  plus  $\ddot{\theta}_2 \cos \theta_2$  minus  $M_2 l_1 l_2^2$  square by  $2 \dot{\theta}_2^2 \sin \theta_2$  minus  $2 M_2 l_1 l_2^2$  square  $\dot{\theta}_1 \dot{\theta}_2 \sin \theta_2$  plus  $M_2 l_1 l_2^2$  square  $2$  by  $\cos \theta_2 \ddot{\theta}_1$  plus  $M_2 l_2^3$  cube by  $3 (\ddot{\theta}_1 + \ddot{\theta}_2)$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin^2 \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_1 \sin \theta_2 \cos \theta_2$  plus  $x^2 \ddot{\theta}_2 \sin \theta_2 \cos \theta_2$ . We are getting very big expressions, lengthy expressions; you must check it by calculations. When you do such

big expressions, there are chances of mistakes. That is why, these days most of these integrations are carried out in computer. One can do the numerical integration.

Now-a-days softwares are there which can obtain the close form integrations also, like Matlab etc; in that you can do. Otherwise numerical integration is preferred, but I thought of showing at least one example of developing the dynamics equation. So, I have taken this. Now, you must verify these things. Put  $m_2 l_2$  is equal to  $M_2$ .  $m_2 l_2$  is the total mass  $M_2$ , then you have  $T_1^2$  that means torque required at joint O, because of the motion of link 2 that is  $M_2 l_1^2 \ddot{\theta}_1 + M_2 l_2^2 \ddot{\theta}_2 + M_2 l_1 l_2 \ddot{\theta}_2 \cos \theta_2 - M_2 l_1 l_2 \dot{\theta}_2^2 \sin \theta_2 - M_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin \theta_2$ .

(Refer Slide Time: 45:13)

**Total torque =  $T = T_1^1 + T_1^2$**

$$= \frac{M_1 l_1^2}{3} \ddot{\theta}_1 + M_2 l_1^2 \ddot{\theta}_1 + \frac{M_2 l_2^2}{3} \ddot{\theta}_2 + \frac{M_2 l_1 l_2}{2} \cos \theta_2 \ddot{\theta}_2 - \frac{M_2 l_1 l_2}{2} \dot{\theta}_2^2 \sin \theta_2 - M_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin \theta_2$$

**We observe that torque of second motor does not depend on the mass of link 1, whereas the torque on the motor at O depends on the mass of both the links.**

The total torque of this one required at point O, joint O of this one comes out to be T is equal to  $T_1^1$  plus  $T_1^2$  that is  $M_1$  by 3  $l_1^2$  square  $\ddot{\theta}_1$  plus  $M_2 l_1^2$  square  $\ddot{\theta}_1$  plus  $M_2 l_2^2$  square by 3  $\ddot{\theta}_2$  plus  $M_2 l_1 l_2$  by 2  $\cos \theta_2$   $\ddot{\theta}_2$  minus  $M_2 l_1 l_2$  by 2  $\dot{\theta}_2^2 \sin \theta_2$  minus  $M_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin \theta_2$ . We see that the torque required is ..... by both the motors. We get the equations which contain the square terms also. Nonlinear terms are there. We have  $\ddot{\theta}_2$  square and all these

things. So, we get the expression for total torque. We observe that torque of second motor does not depend on the mass of link 1, whereas the torque on the motor at O, depends on the masses of both the links. Therefore, these are the expressions for the torques and these equations can be solved.

For any given configuration solving this type of equation, you may have to use numerical method. One can be direct problem in which somebody may give you  $\theta_1$  as a function of time,  $\theta_2$  as a function of time then it is easy. You can just put that, differentiate and get the value of that. In some cases, you may have been prescribed the torque and you have to find out the angular displacements. In that case, the inverse procedure has to be done. So, you have to do some sort of integration because this then becomes a differential equation which has to be solved. Numerical methods can also be used. This is the thing that you have to do.

(Refer Slide Time: 48:11)

If in addition to mass of the links, there is concentrated mass at the end, the equations can be developed in the similar way. Suppose, there is a tip mass  $M_p$  situated at the tip of the second link, then mass per unit length of the second link may be written as,

$m_2 + M_p \delta(x - l_2)$ , where  $\delta(x - l_2)$  the Dirac-Delta function defined at  $l_2$ . Its value is infinite at  $l_2$ , but if we integrate the Dirac-delta function over the small length surrounding  $l_2$ , we will get 1. In the case of non-uniform link,  $m_2$  will be a function of  $x$  instead of a constant quantity.

$$\int M_p \delta(x - l_2)$$

Here we have done simplification in integrations. We have been taking  $m_1$  etc., outside. If it was not so, if  $m_1$  was a function of  $x$ , that means i can take out rod and this thing. then, we have to put inside that and some cases we can integrate given  $m$  as function of  $x$ . In

some cases we have to use the numerical methods only. If in addition to the mass of the links, there is a concentrated mass at the end then what should be done? Then equations can be developed in the similar way. If you have got concentrated mass then suppose there is tip mass for example  $M_p$ , which is situated at the tip of the second link, then same type of expressions can be developed, but the mass per unit length of the second link may be written as  $m_2$  is equal to  $m_2$  plus  $M_p \delta(x - l_2)$ , where  $M_p$  is the peak mass and  $m_2$  is the mass per unit length.  $m_2$  has got the unit of kg per meter, whereas  $M_p$  has got the unit of kg but it has been multiplied by  $\delta(x - l_2)$ , where  $\delta(x - l_2)$  is the Dirac-delta function which is defined at  $l_2$ . Dirac-Delta function is at  $l_2$ , whose value approaches infinity and  $V$ , where velocity is 0. If you integrate Dirac-delta function between limit 0 to  $l_2$ , then you will be getting the value as 1 only. So, Dirac-delta function has got the unit of 1 by meter.

So, its values are finite at  $l_2$  but if we integrate the Dirac-Delta function over the small length surrounding  $l_2$ , we will get 1. In the case of non-uniform link,  $m_2$  will be a function of  $x$  instead of a constant quantity. Therefore, in the integral sign, we can put and that causes no problem. Suppose you have the Dirac-Delta function, we will have the property. Suppose you get some term like  $M_p$ , then  $\delta(x - l_2)$  multiplied by something like  $x \cdot dx$ . So, it will become  $M_p$  the value of that function at  $l_2$ . That means, if you have a function  $F(x)$  which is multiplied by  $\delta(x - l_2)$ , this is nothing but the value of the function of at  $l_2$ . Therefore, that is  $H_G$ . In the case of non-uniform link,  $m_2$  will be a function of  $x$  instead of a constant quantity.

(Refer Slide Time: 51:37)

Thus, all the calculations can be repeated by replacing  $m_2$  by  $m_2 + M_p \delta(x - l_2)$ .

It is interesting to observe that, if both the links are rotating with constant angular velocity then also the torque will be required. In that case, the

torque on the motor at A will be  $\frac{M_2 l_1 l_2}{2} (\dot{\theta}_1)^2 \sin \theta_2$

and the torque on the motor at A will be

$$-\frac{M_2 l_1 l_2}{2} (\dot{\theta}_2)^2 \sin \theta_2 - M_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin \theta_2$$

Thus, all the calculations can be repeated by replacing  $m_2$  by  $m_2$  plus  $M_p \delta x$  minus  $l_2$ . It is interesting to observe that, if both the links are rotating with constant angular velocity then also the torque will be required. Suppose both are moving in a single link, it is not required; but in this case it is required. In that case, the torque on the motor at A will be  $M_2 l_1 l_2$  by  $2 \theta_1 \dot{\theta}_1^2 \sin \theta_2$  because of the angular velocity of the second link. If the second link is stationary then, that torque will not be same. First link is stationary then the torque will not be required. If the first link is not stationary then this will be required and  $\sin \theta_2$  and the torque on the motor at A will be minus  $M_2 l_1 l_2$  by  $2 \theta_2 \dot{\theta}_2^2 \sin \theta_2$  minus  $M_2 l_1 l_2 \theta_1 \dot{\theta}_1 \theta_2 \dot{\theta}_2 \sin \theta_2$ .

We see that although links are moving with constant velocity, still that torque is required because of the second link. We take the torque in inertial system. Now, if  $m_2$  is 0 then there will not be any requirement of the torque.

(Refer Slide Time: 53:25)

In case, the first link is stationary and only the second link rotates, the torque on the second link will be,

$$\frac{M_2 l_2^2}{3} \ddot{\theta}_2$$

i.e., equal to mass moment of inertia times angular acceleration as expected.

In this case for keeping the first link stationary, some torque will have to be applied at O also. Its magnitude is

$$\frac{M_2 l_1 l_2}{2} \cos \theta_2 \ddot{\theta}_2 - \frac{M_2 l_1 l_2}{2} \sin \theta_2$$

In case the first link is stationary and only the second link rotates, the torque on the second link will be  $M_2 l_2^2$  by 3  $\ddot{\theta}_2$ ; that is  $\ddot{\theta}_2$ , basically. That is equal to the mass moment of inertia times the angular acceleration as expected. In this case for keeping the first link stationary, some torque will have to be applied at O also and its magnitude is  $M_2 l_1 l_2$  by 2  $\cos \theta_2 \ddot{\theta}_2$  minus  $M_2 l_1 l_2$  by 2  $\sin \theta_2$ . This way, by applying only the basic principles of the dynamics, we can solve these types of problems. Lot of expression have been developed, but if we apply only the Newton's law to particles and remember the fact that these laws are valid in inertial reference system only, then we can develop the equations for any type of problem.

We have been doing in the previous lectures, basically this. We have been developing other expressions like for rigid body, but basically we apply the equations to particle then we can always get the expressions. It may be simple rod rotating or it may be that robotic manipulator. In that case also, these type of things can be applied. So, that was my purpose of showing this example.
