Introduction to vibration

Module 15 Lecture 37
Forced Vibration

(Damped Undamped)

Last lecture, we studied free vibration problems. Specifically, we studied the behavior of two systems.

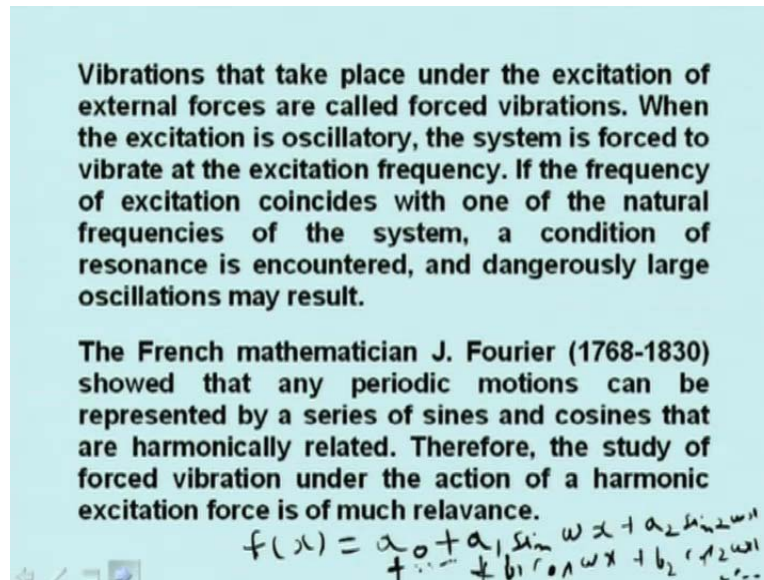

(Refer Slide Time: 01:26)

One is a damped natural vibration and another is undamped vibration. In damped one, the damping is present and in undamped, natural vibration damping is not present. Now, we specifically took two systems. This is the spring mass system. We have studied that problem and then another model was that in which we attached a dashpot. We attach a dashpot here and we put like this. Here, if we make the free body diagram of this, this was having kx , the force. Therefore, governing equation was naturally, $m\ddot{x}$ is equal to minus kx . Whereas in

this system, this is mass m and this is kx . This will basically be $c\dot{x}$. Therefore, governing equation was $m\ddot{x}$ is equal to minus kx minus $c\dot{x}$. No external force term was present.

(Refer Slide Time: 03:30)

In this lecture, today, we are going to study forced vibrations with damping and without damping. Vibrations that take place under the excitation of external forces are called forced vibrations. When we put that in this one, when the excitation is oscillatory, the system is forced to vibrate at the excitation frequency. What happens, when we apply a force on a spring mass system, suppose we know a mass is there and it is held by a spring then we displace the mass. Naturally, we have created a disturbance from its equilibrium position. So, the natural vibrations may start, but the natural vibrations that is free vibrations, they will decay with time because of the presence of the damping.

If damping is not there, then of course these free vibrations will not decay, but because there is a damping, these decay with time. In any system, damping is always present. There is no system in which there is no damping. All systems, because undamped case is just an idealization, therefore what happens? These vibrations will decay, but because there is a force present that keeps vibrating, we are mostly interested in the steady state response. Then the system will vibrate with the excitation frequency. If the frequency of excitation coincides with one of the natural frequencies of the system then we get a condition of resonance in which dangerously large

oscillations may result. Large amount of oscillations take place when there is a condition of the resonance.

Now, we are going to study the mathematical treatment of that forced vibration. French mathematician J Fourier, who was born in 1768 and died in 1830, showed that any periodic motion can be represented by a series of sine's and cosines that are harmonically related. That means you have a periodic function, suppose you have a periodic function $f(x)$, it can be represented by a_0 plus $a_1 \sin \omega x$ plus $a_2 \sin 2\omega x$ like that, there may be so many terms upto infinite. Then you have $b_1 \cos \omega x$ plus $b_2 \cos 2\omega x$ like that. So, cosine and sin terms are there. In a general case, that Fourier, we will not discuss about the Fourier series method.

However, we know that if we have any periodic motion that can be represented by a series of sine's and cosine's. Therefore, the study of forced vibration under the action of a harmonic excitation force is very important, because suppose if we can find out the expressions for that what happens? When the force f is equal to $a_1 \sin \omega t$ then we can take another force f is equal to another $a_2 \sin 2\omega t$. Therefore, under the action of combined terms, the response will also be combined, because this system if we take k and m and even damping coefficient c as a constant, then this is a linear system. That means, we can simply find out the displacement by superposition under the two circumstances.

(Refer Slide Time: 07:56)

Therefore, let us try to study that. This is mass then this is a spring then this is dashpot and this is x . There is a force F acting here. Now, this will be $F_0 \sin \omega t$. Let us assume that F is equal to $F_0 \sin \omega t$ that means you have got a sinusoidal forcing function. This is kx then this is $c\dot{x}$; kx is the restoring force and $c\dot{x}$ is this one. Therefore what happens? Now this is the free body diagram of mass m . There is a force $F_0 \sin \omega t$. This is kx and this is $c\dot{x}$.

(Refer Slide Time: 09:00)

Consider the spring-mass-dashpot system. The mass is displaced by a distance x and its free body diagram is shown. From this figure, we see that the equation of motion is

$$m\ddot{x} + c\dot{x} + kx = F_0 \sin \omega t$$

The solution to this equation consists of two parts, the complementary function, which is the solution of the homogeneous equation and the particular integral.

The particular solution in the equation is a steady-state oscillation of the same frequency ω as that of the excitation. We can assume the particular solution to be of the form

Then consider the spring-mass-dashpot system. The mass is displaced by distance x and its free body diagram is as shown. From this figure, we see that the equation of motion is $m\ddot{x}$ plus because the equation is basically $m\dot{x}$ is equal to minus kx minus $c\dot{x}$. Therefore, it can be written as plus $F_0 \sin \omega t$. Therefore, this can be written as $m\ddot{x} + kx + c\dot{x}$ is equal to $F_0 \sin \omega t$.

Solution to this equation consists of two parts; one is called the complementary function, which is the solution of the homogeneous equation. That means, if we solve $m\ddot{x} + c\dot{x} + kx = 0$, we will get one solution that is called solution of the homogeneous equation. This equation $m\ddot{x} + c\dot{x} + kx = 0$ is called homogenous, because if x equal to a , is the solution then x is equal to constant times a , is also a solution. That means, if one solution is x then naturally cx is also a solution. So, it is totally homogeneous that it is called complementary function. The other one is that particular integral that depends upon the term on the right hand side. In this case, it is $F_0 \sin \omega t$. So, the combined motion is basically just the combination of complementary function and particular integral.

The physical significance of this is that when we displace a mass by some force, then combined effect which we get, is the sum of these two things; that means, natural vibrations, that mass particle starts vibrating in natural mode and then forcing term vibrations are also present. Therefore, the motion is the combination of these two. The particular solution in the equation is a steady-state oscillation of the same frequency ω as that of the excitation.

(Refer Slide Time: 11:58)

$x = X \sin(\omega t - \phi)$

where X is the amplitude of oscillation and ϕ is the phase of the displacement with respect to the exciting force.

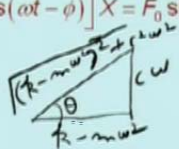

Substituting this in the equation of motion

$$-m\omega^2 X \sin(\omega t - \phi) + c\omega X \cos(\omega t - \phi) + kX \sin(\omega t - \phi) = F_0 \sin \omega t$$

Or,

$$[(k - m\omega^2) \sin(\omega t - \phi) + c\omega \cos(\omega t - \phi)] X = F_0 \sin \omega t$$

Or,

We can assume particular solution to form this one. We just assume, let us see that what happens?

x is equal to let us say $X \sin \omega t - \phi$, where X is the amplitude of oscillation and ϕ is the phase of the displacement with respect to the excitation force. If you substitute this expression in the equation of motion, you get like this; minus $m\omega^2 X \sin \omega t - \phi$, because $X \sin \omega t - \phi$ has been differentiated two times. So, you get minus $m\omega^2 X \sin \omega t - \phi$ plus $c\omega X \cos \omega t - \phi$. It has been differentiated one time plus $kx \sin \omega t - \phi$ is equal to $F_0 \sin \omega t$, or $k - m\omega^2 \sin \omega t - \phi$ plus $c\omega \cos \omega t - \phi$ into x is equal to $F_0 \sin \omega t$, that expression we got.

We have to find out the expression for x . If we carry out trigonometry here, can I simplify this expression, $k - m\omega^2 \sin \omega t - \phi$. If we just see that if I can represent them in trigonometric form, if this is θ and if this is $k - m\omega^2$ and this is $c\omega$ and this is under root of $k - m\omega^2$ plus ω^2 plus $c^2 \omega^2$. Finally, we can get $\sin \theta$ type of term.

(Refer Slide Time: 14:03)

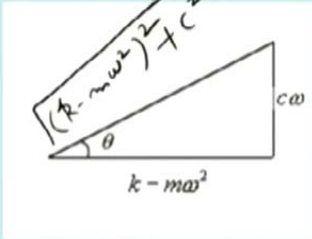

$$\begin{aligned}
 & \left[\frac{k - m\omega^2}{\sqrt{(k - m\omega^2)^2 + c^2\omega^2}} \sin(\omega t - \phi) + \frac{c\omega \cos(\omega t - \phi)}{\sqrt{(k - m\omega^2)^2 + c^2\omega^2}} \right] \times \sqrt{(k - m\omega^2)^2 + c^2\omega^2} \\
 &= F_0 \sin \omega t \\
 & \sqrt{(k - m\omega^2)^2 + c^2\omega^2} [\cos \theta \sin(\omega t - \phi) + \sin \theta \cos(\omega t - \phi)] \times \\
 &= F_0 \sin \omega t \quad \sin(\omega t - \phi + \theta)
 \end{aligned}$$

where θ is shown in the adjoining figure.

If we divide this whole thing by $k - m\omega^2$ divided by that thing this we are dividing this thing by this expression that means square of these two terms this and this then take the under root, we divide by $\sin \omega t$. Similarly, here $c\omega t$ and here this is $\cos \omega t$ minus ϕ , like that multiplied; since we divided by under root $k - m\omega^2$ plus $c^2\omega^2$. Therefore, we have to multiply it also by this thing then this expression remains same. Therefore, the previous expression and this expression is basically same. This is equal to $F_0 \sin \omega t$.

We can take this common. Here $k - m\omega^2$ whole square plus $c^2\omega^2$ square multiplied by $\cos \theta$, because this can be written $\cos \theta$ and this is $\sin \theta \cos \omega t$ is equal to $F_0 \sin \omega t$ where θ is basically like this.

(Refer Slide Time: 15:16)

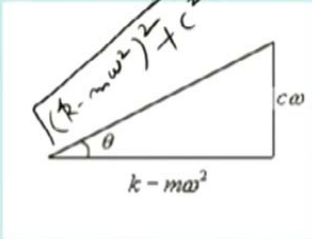

Simplifying the above equation we may write:

$$\sqrt{(k - m\omega^2)^2 + c^2\omega^2} [\sin(\omega t + \theta - \phi)] X = F_0 \sin \omega t$$

This is k minus m omega square and this is c omega. Therefore, by Pythagoras theorem, this is k minus m omega square plus c square omega square. Simplifying this expression, we may write this as $\sin \omega t$ plus ϕ , because this is the formula of $\sin \omega t$ plus ϕ . This one $\cos \omega t$ minus θ this is $\sin \omega t$ plus θ minus ϕ basically, because this is a b . So, $\sin \omega t$ minus ϕ plus θ . Apply the formula of $\sin a$ plus b ; so, $\sin a \cos b$. So, $\sin \omega t$ minus ϕ $\cos \theta$ $\sin \cos \omega t$ minus ϕ and this is θ . So, this is $\sin \omega t$ minus ϕ $\cos \theta$ $\cos \omega t$ minus ϕ $\sin \theta$. So this is like this.

In this expression this is ωt this is equal to like that so $\sin \omega t$ minus ϕ plus θ is equal to $F_0 \sin \omega t$. We have obtained this expression.

(Refer Slide Time: 16:54)

Simplifying the above equation we may write:

$$\sqrt{(k - m\omega^2)^2 + c^2\omega^2} [\sin(\omega t + \theta - \phi)] X = F_0 \sin \omega t$$

If we compare the right and left hand side of this thing, $\sin \omega t$, this has to be equal. So, $\omega t + \theta - \phi$ should be equal to 0.

(Refer Slide Time: 17:08)

Comparing the left and right hand sides of the expression, we see that

$$X = \frac{F_0}{\sqrt{(k - m\omega^2)^2 + (c\omega)^2}} \text{ and } \omega t + \theta - \phi = \omega t$$

which gives

$$\phi = \theta = \tan^{-1} \frac{c\omega}{k - m\omega^2}$$

We can write X and ϕ in the following form,

That means we have to say, where X equal to F_0 by this one and $\omega t + \theta - \phi$ is equal to ωt . This condition has to be because for all t , if it has to be correct then this relation has to be satisfied which gives ϕ is equal to θ ; that means, which is equal to

basically, $\tan^{-1} \frac{c\omega}{k - m\omega^2}$. We can say $\tan \theta$ is equal to $c\omega$ divided by this thing. So, $\tan \theta$ is equal to $\tan^{-1} \frac{c\omega}{k - m\omega^2}$. We can write X and ϕ . So, X is equal to $\frac{F_0}{k} \frac{1}{\sqrt{\left(1 - \frac{m\omega^2}{k}\right)^2 + \left(\frac{c\omega}{k}\right)^2}}$ plus $c\omega$ square.

(Refer Slide Time: 18:01)

$$X = \frac{F_0 / k}{\sqrt{\left(1 - \frac{m\omega^2}{k}\right)^2 + \left(\frac{c\omega}{k}\right)^2}}$$

and

$$\tan \phi = \frac{\frac{c\omega}{k}}{1 - \frac{m\omega^2}{k}}$$

We can write X as $\frac{F_0}{k}$ divided by $\sqrt{\left(1 - \frac{m\omega^2}{k}\right)^2 + \left(\frac{c\omega}{k}\right)^2}$. It is to be noted that $\frac{F_0}{k}$ is the static deflection of the spring under the action of that force F_0 . Maximum amplitude of the force is F_0 . So, if you apply maximum force then you will get the static deflection as $\frac{F_0}{k}$.

(Refer Slide Time: 18:33)

Putting,

$$\omega_n = \sqrt{\frac{k}{m}} = \text{natural frequency of undamped oscillation}$$

$$c_c = 2m\omega_n = \text{critical damping}$$

$$\zeta = \frac{c}{c_c} = \text{damping factor}$$

we can write

$$\frac{c\omega}{k} = \frac{c}{c_c} \frac{c_c\omega}{k} = 2\zeta \frac{\omega}{\omega_n}$$

$$\frac{m}{k} = \frac{1}{\omega_n^2}$$

We know that ω_n is equal to under root k by m that is the natural frequency of undamped oscillation. Now, C_c is equal to $2m$ times ω_n which is called critical damping and zeta is equal to C by C_c , that is called damping factor. We can write $c\omega$ by k as c by C_c $C_c\omega$ by k , that means 2 zeta ω by ω_n , because C_c is equal to $2 C_c$ by C_c $2g$. This C_c is equal to $2 m$ into ω_n and m by k is basically 1 by ω_n square. We just do that simple. So, we will keep $C\omega$ by k is $2\zeta\omega$ where ζ is damping factor ω by ω_n .

(Refer Slide Time: 19:58)

This gives us

$$\frac{X}{(F_0/k)} = \frac{1}{\sqrt{\left[1 - \left(\frac{\omega}{\omega_n}\right)^2\right]^2 + 2\zeta\left(\frac{\omega}{\omega_n}\right)^2}} \quad \text{-----(A)}$$

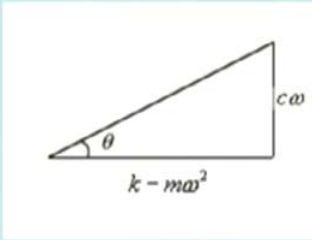

and

$$\tan \phi = \frac{2\zeta\left(\frac{\omega}{\omega_n}\right)}{1 - \left(\frac{\omega}{\omega_n}\right)^2} \quad \text{-----(B)}$$

This gives us X divided by F_0 by k is equal to 1 under root divided by under root 1 minus omega by omega_n Whole Square whole square plus 2zeta omega by omega_n whole square. This is also zeta. This tan and tan phi is equal to 2zi omega by omega_n 1 minus omega by omega_n Whole Square.

Why we have written this in this form? As we already mentioned, F_0 by k is the maximum static deflection. X divided by F_0 by k gives the ratio of that dynamic amplitude to static amplitude or maximum static deflection. Similarly, here we get phi, phi is the phase angle, because we started like this.

(Refer Slide Time: 21:09)

Simplifying the above equation we may write:

$$\sqrt{(k - m\omega^2)^2 + c^2\omega^2} [\sin(\omega t + \theta) - \phi] X = F_0 \sin \omega t$$

We assumed that the force was $F_0 \sin \omega t$ but our displacement was $\sin \omega t$ minus ϕ ; that means, there was a phase difference between two. So, this gives the idea about the phase difference.

(Refer Slide Time: 21:23)

Comparing the left and right hand sides of the expression, we see that

$$X = \frac{F_0}{\sqrt{(k - m\omega^2)^2 + (c\omega)^2}} \text{ and } \omega t + \theta - \phi = \omega t$$

which gives

$$\phi = \theta = \tan^{-1} \frac{c\omega}{k - m\omega^2}$$

We can write X and ϕ in the following form,

In this case, if c is equal to 0 then there is a no phase difference. There is no damping present, then but if there is a damping present then there is a phase difference between the applied force

and the response we get. So, that is because effect of damping when it is like that, so that damping also introduces a force. Therefore, this comes X is equal to F_0 by k under root 1 minus m omega square by k whole square plus c omega by k whole square and ϕ is equal to C omega by K whole divided by 1 minus m omega square by K . In this, this is $\tan \phi$.

(Refer Slide Time: 22:33)

Notice that in equation (A), $\frac{F_0}{k}$ is the static deflection and X is the amplitude of vibration. Therefore, the ratio $\frac{X}{F_0/k}$ is often called the magnification factor and depends on ω . Plots of magnification factor versus ω/ω_n have been shown for three values of damping factor. When the damping is very small the magnification factor is very large in the vicinity of natural frequency. Hence, the forcing frequency should not be close to natural frequency, if the vibrations have to be avoided. One can see that for large value of ω/ω_n , the magnification factor becomes very small. Hence, the operating

Using this, now notice that in this equation A, F_0 by k is the static deflection and X is the amplitude of vibration. So, amplitude of vibration depends naturally, what is the frequency ratio? That means ω by ω_n . What is the natural frequency? Therefore, the ratio X by F_0 by k is often called the magnification factor. How much times the dynamic amplitude is more than the static deflection and depends on ω .

(Refer Slide Time: 23:29)

Now, plots of magnification factor versus ω by ω_n have been plotted, we have shown. Actually for three damping values that is; τ is equal to 0.01 that is very low damping, τ is equal to 0.2 and τ is equal to 1. In this case, at ω by ω_n equal to 1. If damping is very low then a resonance type condition occurs. So, we see that the magnification becomes under almost infinity. Otherwise also, nearby this region, near the natural frequencies, the magnification factor becomes very high.

However, if we have critical damping then magnification factor is always less than 1; that means if ω is very high compared to the natural frequency then the magnification factor approaches zero. This is very interesting, that means at ω is equal to 0. That means in static case, if you just apply some force then there will be displacement. That will be basically X by F_0 by k . Therefore, you will get the same type of thing, but if we apply a very high frequency then displacement approaches 0. Why? Because the mass is not able to respond, because of the dashpot it is not able to move at all. Therefore, there approach is 0.

Similarly, but when τ is equal to 0.2 then at resonance it will be very high, but of course, it will not be infinite. If there is a damping present in the system, it will not allow the vibration to become infinite, of course it becomes very high. Similarly, in the case of the low damping, it is like this.

When the damping is very small, the magnification factor is very large in the vicinity of natural frequency. Hence, the forcing function should not be closed to natural frequency, if the vibrations have to be avoided. For very large value of ω by ω_n , the magnification factor becomes very small. Hence, the operating or forcing frequency should be four to five times the natural frequency, for best results. That means, if you have the natural frequency of some system is 100 hertz. If you have the forcing function frequency at 400 hertz then you know that it will not. We might have noticed these type of examples, like a fan makes lot of noise when it is run at a low rpm, but when the rpm is increased, then it does not make that much noise because of this phenomena.

Similarly, some cars also, when they run at a low speed then they will show vibrations, but at high speed the vibrations are not seen.

(Refer Slide Time: 27:02)

Undamped forced vibration:

For undamped vibration the damping factor ζ is zero. Thus,

$$X = \frac{F_0/k}{1 - \left(\frac{\omega}{\omega_n}\right)^2} \quad \frac{F_0/k}{1 - \left(\frac{\omega}{\omega_n}\right)^2} = 0$$

and $\phi = 0$

The complementary solution, known as the transient solution is of no special interest since with time it dies out with small amount of damping which can never be completely eliminated. we have not discussed about the complementary solution, which is called transient solution. This is of no special interest.

For undamped forced vibration, now undamped, one damping factor zeta is equal to 0. Thus, we get X is equal to F_0 by k $1 - \omega$ by ω square and we get phi is equal to 0. There is no phase difference between the forcing function and the response. Then we are getting this type of expression. Here also, it is seen that if ω is very small then X is equal to, of course F_0 by k , but if ω is very large then this X will approach 0 because of this term F_0 by k . So, this

term will approach 0; so, F_0 by k divided by minus ω by ω_n square. This term is approaching infinity. You get something like, here 0. So, this is the interesting thing.

If you have a spring mass system like this, there is a very flexible spring. If you apply force of a very high frequency, this will not be able to move that means it will not carry out any vibration.

Now, complementary solutions known as the transient solution, is of no special interest since with time it dies out with a small amount of damping which can never be completely eliminated. Therefore, we have not discussed about the complementary solution which are called transient solution. This is of no special interest. However, in undamped case, one can study actually and one can get some insight about the cases in which damping is almost 0.

(Refer Slide Time: 29:35)

Let us discuss, the other type of problem that is the problem involving the support motion. What is this, that if you have kept this on a support, this is a fixed support like this and this is mass and this is a spring and this is dashpot. Now, support itself is getting excited. Supporting is being excited and support is undergoing the displacement y and mass itself is undergoing the displacement x . This is the equilibrium position of the mass and x is the displacement from this position.

(Refer Slide Time: 30:09)

Support motion

In many cases the dynamical systems are excited by the motion of the support point. Let y be the harmonic displacement of the support point. Measure the displacement x of the mass from an inertial reference. We can make the free body diagram of the mass. It is subjected to spring and viscous forces. The equation of motion is

$$m\ddot{x} = -k(x - y) - c(\dot{x} - \dot{y}) - m\ddot{y}$$

\downarrow
 $m(\ddot{x} - \ddot{y})$

$\underbrace{x - y}_z$

Let y be the harmonic displacement of the support point. If we measure the displacement x of the mass from an inertial reference, we can make from the free body diagram of the mass. It is subjected to spring and viscous force. Equation of motion is like this. This is mass, it is stretched. Suppose, you have pulled the mass by amount x , but the support by that time also has moved by a distance y . So, net stretching of the spring is $k(x-y)$. Therefore, the spring will provide a force $k(x-y)$ in this direction.

Similarly, the net velocity of the mass from inertial reference frame, means from outside observer which is on a fixed frame, which is from that frame he is observing and he says that net velocity of the mass is \dot{x} minus \dot{y} . This is the velocity that is the relative velocity, because otherwise the absolute velocity of the particle is \dot{x} ; mass m is \dot{x} . Therefore, support itself is moving with \dot{y} . Therefore, net velocity is relative velocity between this thing is \dot{x} minus \dot{y} . That means dashpot is there. So, dashpot's piston is moving with \dot{x} . Cylinder itself is moving with \dot{y} . So, difference is \dot{x} minus \dot{y} .

Therefore, $c\dot{x}$ minus \dot{y} is equal to $k(x-y)$. Now, put z is equal to x minus y . If we put z is equal to x , we get $m\ddot{x}$ first, by Newton's law, $m\ddot{x}$ is equal to minus kx minus y minus $c\dot{x}$ minus \dot{y} . Now, we are getting the terms x minus y . Therefore, better to write it like z , the y variable gets reduced like that.

You say z is equal to x minus y , we get $m\ddot{z}$ double prime. Here, we do not have any y term. So, if we put that here also, $m\ddot{x}$ dot minus y dot then since we have added here, therefore, from here we can subtract that thing. We can add here also so it becomes minus $m\ddot{y}$ dot. Therefore, it becomes $m\ddot{z}$ double dot plus $c\dot{z}$ dot plus kz is equal to minus $m\ddot{y}$ double dot, and this is y is equal to, if we assume that support is getting excited by y is equal to $y \sin \omega t$. Therefore, this is minus $m\omega^2 y \sin \omega t$. So, you are getting this thing.

(Refer Slide Time: 33:34)

Solution can be immediately written as,

$$z = Z \sin(\omega t - \phi)$$

$$Z = \frac{m\omega^2 Y}{\sqrt{(k - m\omega^2)^2 + (c\omega)^2}} \quad Z = \frac{m\omega^2 Y}{m \sqrt{\left(\frac{k}{m} - \omega^2\right)^2 + c^2 \omega^2}}$$

$$\tan \phi = \frac{c\omega}{k - m\omega^2} = \frac{m\omega^2 Y}{m \sqrt{(\omega_n^2 - \omega^2)^2 + c^2 \omega^2}}$$

$Z = X - Y$

If the frequency ratio $\frac{\omega}{\omega_n}$ is large, then $\frac{Z}{Y} = 1$ for all values of the damping ratio ζ .

$$\frac{Z}{Y} = \frac{m\omega^2 Y}{m\omega^2} = 1$$

Its solution can be immediately written as z is equal to $Z \sin \omega t$ minus ϕ . Because this type of thing we have already done. This is like a force. Instead of the force $F_0 \sin \omega t$, we are having $m\omega^2 Y$. So, $m\omega^2 Y$ is like a force. So, z is equal to $Z \sin \omega t$ and Z is equal to $m\omega^2 Y$ under root k minus $m\omega^2$ whole square plus $C\omega$ square and $\tan \phi$ is equal to $C\omega$ k minus $m\omega^2$ square.

In this case, if the frequency ratio ω by ω_n is large then Z by Y becomes equal to one for all values of the damping ratio. Let us discuss this point in detail. We have seen $m\omega^2 \tan \phi$ Z is equal to $m\omega^2 Y$ under root k minus $m\omega^2$ plus $C\omega$ square. Now, $\tan \phi$ is equal to $C\omega$ k minus $m\omega^2$ square.

In this case, Z/Y is equal to one for all values of the damping ratio. How can we prove this one? Let us write Z is equal to ω by ω_{a_n} is large; that means, Z is equal to $m \omega^2 Y$ divided by k minus m . So, we take that. Maybe we can take m square common, so, m can be taken common here. This becomes k by m . k by m minus ω^2 whole square plus $C^2 \omega^2$. This is equal to $m \omega^2 Y$. This is m and this will become k by m minus ω^2 whole square. So, this is under root $\omega_{a_n}^2$ minus ω^2 whole square plus $C^2 \omega^2$.

Now, ω by ω_{a_n} is large that means ω_{a_n} is smaller, much smaller in fact in comparison to ω^2 . Therefore, here $\omega_{a_n}^2$ minus ω^2 can be written as ω^2 . So, this will become ω to the power 4 and this becomes $m \omega^2 Y$ divided by m under root ω to the power 4 plus $C^2 \omega^2$. Since ω is a very large number, ω whole term is very high in comparison to $C^2 \omega^2$.

First of all, damping is always less than 1 and ω . Therefore, what happens? This I can write as $m \omega^2 Y$ divided by $m \omega^2$ that is ω^2 . So, this is equal to Y . Therefore, Z is equal to Y . Irrespective of damping Z is equal to Y if ω by ω_{a_n} is large. That means, if the support is being excited by a very high this one then Z will be equal to Y , but then what happens, Z is equal to Y but Z is basically X minus Y . That means, we have said Z is equal to X minus Y and so, that is equal to Y . So, what happens is that Z/Y is almost this one. That means, the relative displacement is almost same as the support displacement.

(Refer Slide Time: 38:57)

Using the characteristic of this type of response, you know that we have got response and understanding that we can design various types of systems. You know what is our primary interest? Sometimes, you have to design the system for measuring the acceleration. Sometimes, you have to isolate the vibrations. So, these types of things are there.

(Refer Slide Time: 39:35)

Undamped forced vibration:

For undamped vibration the damping factor ζ is zero. Thus,

$$X = \frac{F_0/k}{1 - \left(\frac{\omega}{\omega_n}\right)^2}$$

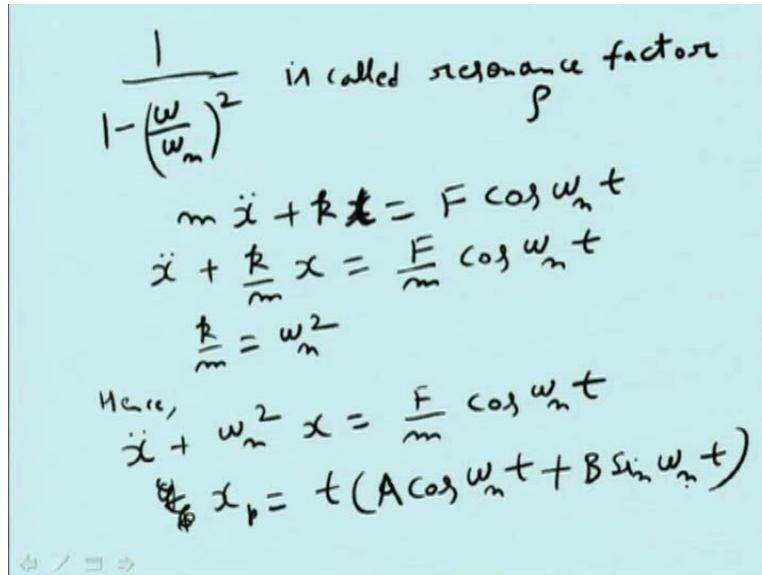

$$\frac{F_0/k}{1 - \left(\frac{\omega}{\omega_n}\right)^2} = 0$$

and $\phi = 0$

The complementary solution, known as the transient solution is of no special interest since with time it dies out with small amount of damping which can never be completely eliminated. we have not discussed about the complementary solution, which is called transient solution. This is of no special interest.

This briefly we have discussed. Let us discuss one or two other interesting things. This factor, which you see here, F_0 by k 1 minus ω by ω_n square whole square, if ω by ω_n becomes equal to 1 , this will become 0 .

(Refer Slide Time: 39:53)

$\frac{1}{1 - \left(\frac{\omega}{\omega_n}\right)^2}$ is called resonance factor ρ
 $m \ddot{x} + k x = F \cos \omega_n t$
 $\ddot{x} + \frac{k}{m} x = \frac{F}{m} \cos \omega_n t$
 $\frac{k}{m} = \omega_n^2$
 Hence,
 $\ddot{x} + \omega_n^2 x = \frac{F}{m} \cos \omega_n t$
 $x_p = t(A \cos \omega_n t + B \sin \omega_n t)$

This factor is 1 by 1 minus ω by ω_n square is called resonance factor, ρ . We can denote it by ρ . Therefore, if ω is equal to 0 , the resonance factor is 1 . If ω is equal to very large, resonance factor is 0 .

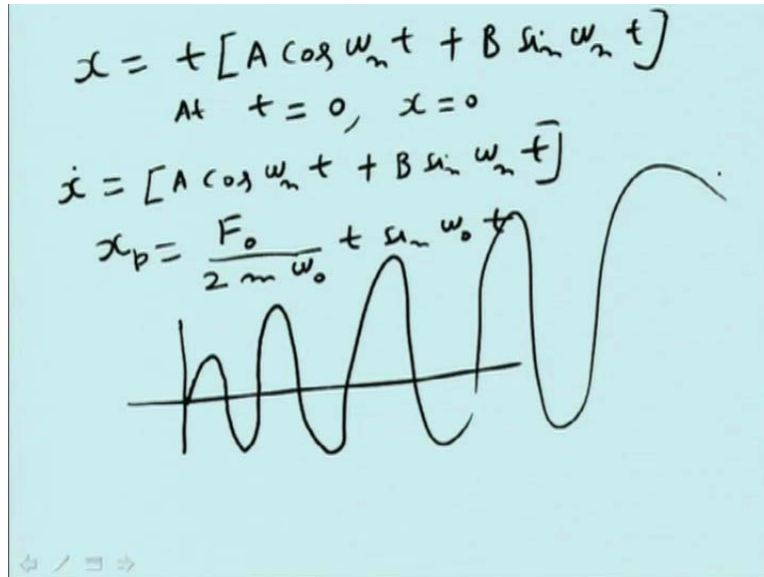

If ω is equal to ω_n resonance factor is infinity. We have seen that you perhaps get the idea that at ω is equal to ω_n , that amplitude of the vibration becomes very high. Let us solve the differential equation when there is a resonance. We know that the differential equation, suppose $m \ddot{x} + k x$ is equal to $k t$ say x , $k x$ is equal to $F \cos \omega t$. Let us say, ω is ω_n . So, $\omega_n t$ and this can be written as $\ddot{x} + \frac{k}{m} x$ is equal to $\frac{F}{m} \cos \omega_n t$. Now, $\frac{k}{m}$ is equal to ω_n^2 . Hence, $\ddot{x} + \omega_n^2 x$ is equal to $\frac{F}{m} \cos \omega_n t$. This is the differential equation which has to be solved.

Here, we can see that, if we just put x is equal to $A \sin \omega t$, that will not satisfy this differential equation in this case, because this is the thing therefore, in this particular case, when the you are getting that same ω_n here and ω_n here like that, therefore, you will get a

particular solution. In this case, x_p is equal to t times $A \cos \omega_n t$ plus $B \sin \omega_n t$ that is it and for this C a. Now, we can have these are the constants. We can have cases.

Let us see, what happens when x is equal to 0 at time t is equal to 0 and \dot{x} is also equal to 0, that means displacement and velocity both component are 0. So, what will happen?

(Refer Slide Time: 43:54)

$$x = t [A \cos \omega_n t + B \sin \omega_n t]$$

At $t = 0, x = 0$

$$\dot{x} = [A \cos \omega_n t + B \sin \omega_n t]$$

$$x_p = \frac{F_0}{2m\omega_0} t \sin \omega_0 t$$

This will become, at t is equal to 0. So, let us write the solution again. x is equal to t and this is $A \cos \omega_n t$ plus $B \sin \omega_n t$. Now at t is equal to 0, x is equal to 0. Let us see \dot{x} is equal to $A \cos \omega_n t$ plus $B \sin \omega_n t$. So, we have to put that condition and after that, we will get some solution which will be equal to x_p is equal to F_0 divided by $2m \omega_0 t \sin \omega_0 t$. That means, at natural frequency the vibrations will always keep increasing. So, this amplitude of vibration will always keep increasing. So, this type of phenomena will come. So, with time the magnitude always keeps on increasing. This is what we observe. This is the type of resonance. So, this condition has to be avoided.

(Refer Slide Time: 46:07)

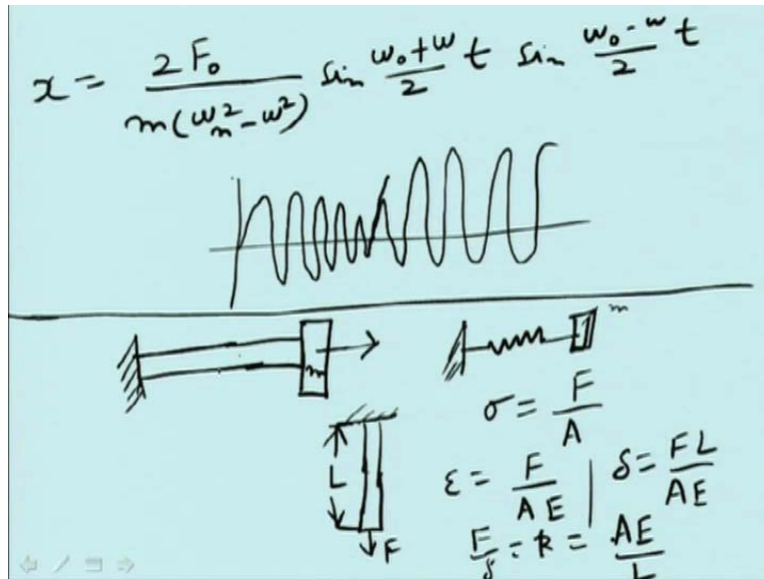

$$\begin{aligned}
 \omega &\approx \omega_n \\
 x_p &= \frac{F_0}{m(\omega_n^2 - \omega^2)} \cos \omega t \\
 &= \frac{F_0}{k \left[1 - \left(\frac{\omega}{\omega_n} \right)^2 \right]} \cos \omega t \\
 x &= C \cos(\omega_n t - \phi) + \frac{F_0}{m(\omega_n^2 - \omega^2)} \cos \omega t \\
 x &= \frac{F_0}{m(\omega_n^2 - \omega^2)} (\cos \omega t - \cos \omega_n t)
 \end{aligned}$$

Let us see that if in case damping is very small and your omega is very near to omega 0, that means omega is almost omega_n then x is equal to F_0 divided by m omega_0 square. This is omega_n square minus omega square cos omega t. This is the particular integral and this can be written as F_0 divided by A_1 minus omega by omega_n whole square and this is cos omega t.

Therefore we consider that even if there is no damping, let us take the case of no damping, then there will be a homogeneous solution also. That will be the complementary part. Complementary function is given by C is a constant cos times omega_n t minus phi, where phi is some angle. Therefore, x is equal to C cos omega_n t minus phi plus F_0 divided by m omega_n square minus omega square cos omega t. This term has come like this. In this, we put the condition that at time t is equal to 0, x is equal to 0 and at time t dot t is equal to 0, x dot is also 0.

That means, we are applying the forcing function at the time when the particle is at rest and from that equilibrium position. Then we will not show that required algebra. Then C and phi can be eliminated and you get x is equal to F_0 divided by m. This will be equal to omega_n square minus omega square. This is cos omega t minus cos omega_n t. So, this can be written as cos omega t minus cos omega_n t. We have the formula for cos C minus cos t.

(Refer Slide Time: 50:10)

This can be written as, x is equal to $2F_0$ divided by $m \omega_n^2 - \omega^2$ $\sin \frac{\omega_0 + \omega}{2} t \sin \frac{\omega_0 - \omega}{2} t$. So, if we plot this thing here, plot may look something like this and then again it goes like this. What happens, because $\omega_0 - \omega$ is very small, therefore, this time period will be very large and we will get the phenomena of beats type of thing. So, here we will be getting the beats type of thing. Like that, we can actually study different type of problems.

We will conclude here. So, today I have discussed about forced vibration problem in which we considered damping and this one. Let us consider the cases, you will always not getting a spring mass system. Sometimes you have got the axial rod, if you have got axial rod and you are applying a force. Here, there may be a mass and you are applying a force here. Even this type of problem can be solved by a spring mass system. So, you model it like a spring and this is the mass. Some portion of the rod mass can also come here and it can be damped at that point and then it becomes like that one.

Supposing you are applying the displacement; this is the force, this is a rod of length L and this is the force. If you apply a force F , cross sectional area is A . Therefore, this will give stress is equal to F by A and strain is equal to F by A divided by A times E . E is the Young's modulus of elasticity. Therefore, displacement δ of the end point is equal to FL divided by AE . F by δ

is called stiffness k that is equal to AE by L . In this case, the spring constant can be written as AE by L and you can actually solve this problem. So, axial vibrations of this system will be more, having more frequency if A is more.

(Refer Slide Time: 54:26)

Similarly, if you have some cantilever beam type of thing here and if you apply some load δ here, you have F is equal to PL^3 by $3EI$, δ is equal to PL^3 by $3EI$. This is known from the strength of material. You will come to know about that thing experimentally. Otherwise, what happens? Take a cantilever beam. Apply some force and measure its deflection. Then you know that one can plot P versus δ P is the force and slope of this gives you stiffness dP by $d\delta$. As the length increases, its stiffness decreases.

Therefore, you can do that one simple experiment. You can make that you take a beam type of thing and here between two adjustable clamps you put it and clamp it properly from some screw. You can always see that when the length was large and if you displace it slightly, you can observe its natural vibrations. It will vibrate with a longer time period that means less frequency. If the same thing you displace and you make like this thing has been displaced this side and now you have like this here. If you vibrate then the frequency of vibration will be very high and this is how it will be doing. Therefore, these types of simple experiments one can do and one can observe. In the next lecture, we will discuss the vibration of rigid bodies.
