**Module 15 Lecture 38**  
**Vibration of Rigid Bodies Part-1**

Today, I am going to speak on vibration of rigid bodies. In this course, we will be discussing the vibrations of single degree of freedom system, by degree of freedom is meant independent coordinates to describe the system. For example, in the previous lectures, we have discussed the vibrations of a spring mass system with damping or without damping.

(Refer Slide Time: 01:54)

We obtained only one dimensional equation. We had  $x$ , position of the mass or that particle is described only by  $x$ . So, independent coordinate is  $x$ ; therefore, this is a single degree of freedom system. If I would have kept like this, suppose there are mass and this was the spring, another spring, another mass; Then this would have become 2 degree of freedom system, because I need to tell the position of this mass, then I need to tell the position of another mass, so, 2 degree of freedom system.

Like that we have 3 degree of system. If there are three masses attached by springs, because I need to locate the position of three masses. We discussed in the first lecture itself the concept of continuum, where we consider that the body is a continuous matter, mass is continuous. Therefore, in this there are infinite number of particles actually. As such, if the body can undergo deformation, then there are infinite degrees of freedom possible.

However, we know that we are studying rigid body, and in rigid body, if a particle is having 3 degrees of freedom and body composed of the particle has basically 6 degree of freedom. In rigid body, the degrees of freedom get reduced and they become only 6. Similarly, the particle we know, although the particle has 3 degree of freedom system, when we discussed the spring mass motion then we assumed that the particle is constrained to move in one direction only. It is not moving in the other two directions. Therefore, it has got 1 degree of freedom. Other 2 degrees are other state.

If the body rigid body is there then that rigid body can undergo 6 degree of freedom and three translations. The center of gravity can move in x y and z direction. Once we fix the center of gravity, then the body can be oriented in three ways by theta phi and another angle alpha. However, if we restrict the body to plane then the body has only 3 degrees of freedom. A rigid body in x-y plane is only having 3 degrees of freedom, because it can be moved along x, it can be moved along y then it can be rotated about the z axis. If we just have its degrees of freedom may be  $x_c$   $y_c$  that is coordination and plus its orientation theta.

However, if we somehow constrained the motion of the body and allow it to have only 1 degree of freedom system, then such problems can also be solved, means with whatever we have discussed that means which in the scope of our present course. Now, this rod has been hinged at one point and therefore, it is not able to move in x and y direction. This point is restrained, but it can rotate. So, it is having a single degree of freedom.

Why we cannot study the vibration of these types of things also, it may be rigid bodies they may be undergoing this thing.

(Refer Slide Time: 06:37)

Planar rigid body vibration is similar to the analysis of particle vibration. In particle vibrations, the variable of interest is one of translations, while in rigid body vibrations, the variable of primary concern is one of rotation (  $\theta$  ).

In the case of torsional system, the total torque including the inertia torque is summed up to zero. The resultant equation for a single degree of torsional system would be,

$$I \frac{d^2\theta}{dt^2} + K_t \theta + c \frac{d\theta}{dt} = T$$

So, planar rigid body vibration is similar to the analysis of particle vibration. In fact, when the particle can be considered as a complete rigid block, also composed of so many particles, because it is under going only translation and all particles are having same velocity and same acceleration, same type of displacement from a particular datum. Therefore, in particle vibrations the variable of interest is one of translation; while in rigid body vibrations, the variable of primary concern is one of rotation theta. You know that, we just go to this one. In the case of when it is theta so, before that let me tell the concept of the torsional system. Let us quickly go to that one.

(Refer Slide Time: 07:50)

In linear springs, there is a spring and if you apply a force  $F$ , the spring gets deflected. Suppose this deflection is  $\delta$ . Then  $k$  is equal to  $F$  by  $\delta$ , where  $k$  is called the spring constant and it is having the unit of Newton per meter. In torsional system, this is suppose you have a torsional spring which can be indicated by like this here. This is the spring and if I suppose fix it here and if I apply some torque  $T$  here then the spring gets displaced.

Angular displacement is there. We say  $T$  is equal to  $k_t$  times  $\theta$ . Now, unit of torque is equal to Newton meter  $k_t$  and this is radian per second. This is what happens, the dimension of  $k_t$  this is radian only. Therefore, dimension of that thing will be Newton meter. So,  $k_t$  will be Newton meter. So, what happens now, going back to the previous slide.

(Refer Slide Time: 09:47)

where  $I$  is the moment of inertia of the rotor,  $\theta$  is the angular displacement,  $K_t$  is the torsional spring stiffness,  $c$  is the damping factor and  $T$  is the external torque.

Let us take a rod here. It is fixed here. A torsional spring is with this. When the rod rotates by  $\theta$  then a restoring moment is developed; that is  $k_t$  times  $\theta$ . That restoring moment will be  $k_t$  times  $\theta$  and this side, we have kept a linear spring, whose spring constant is  $k$ .

(Refer Slide Time: 10:20)

Planar rigid body vibration is similar to the analysis of particle vibration. In particle vibrations, the variable of interest is one of translations, while in rigid body vibrations, the variable of primary concern is one of rotation ( $\theta$ ).

In the case of torsional system, the total torque including the inertia torque is summed up to zero. The resultant equation for a single degree of torsional system would be,

$$I \frac{d^2\theta}{dt^2} + K_t \theta + c \frac{d\theta}{dt} = T$$

In this case, the total torque including the inertia torque is summed up to 0; that is D'Alembert's principle, or we can say that we can apply the Newton's law generalized to that

angular coordinates or angular degree coordinates. Then you have  $I \frac{d^2 \theta}{dt^2}$  plus  $K_t \theta$  is equal to  $c \frac{d \theta}{dt}$  is equal to  $T$ .  $I \frac{d^2 \theta}{dt^2}$  is the inertial torque.  $\frac{d^2 \theta}{dt^2}$  is the angular acceleration with unit of  $1$  by second square and  $I$  is having the unit of mass moment of inertia. So it is kg meter square.  $K_t$  is Newton meter,  $c$  is the viscous damping effect.

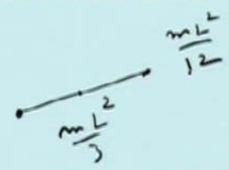

Just like, there we had  $c$  times  $\dot{x}$  and here, I am putting  $c$  times  $\dot{\theta}$ . That means,  $c \frac{d \theta}{dt}$  must be equal to applied torque. This is the equation;  $I \frac{d^2 \theta}{dt^2}$  plus  $K_t \theta$  plus  $c \frac{d \theta}{dt}$ . If  $T$  is equal to  $0$  then this becomes the case of 3 vibration and you get this thing. The equation is similar to what we have studied in a spring mass system, only  $\theta$  is replacing  $x$ . Therefore, this  $K_t$  is called torsional spring stiffness,  $c$  is the damping factor and  $T$  is the external torque.

(Refer Slide Time: 12:13)

Shown is a rigid rod of mass  $M$  and length  $L$ , connected by torsional spring at one end and linear spring at the other end. Let us write down the governing differential equation

(i) Inertia moment =  $-I\ddot{\theta}$

where  $I$  is the moment of inertia of the bar about the left end.

$$I = \frac{mL^3}{3}$$

Inertia moment is minus  $I \ddot{\theta}$ .  $I$  is the moment of inertia of the bar about the left end and this is given by  $\frac{mL^3}{3}$ . You have a rod and its moment of inertia, uniform slender rod, its moment of inertia about this point is  $\frac{mL^3}{3}$ . About its cg, it is  $\frac{mL^3}{12}$  so  $I$  equal to  $\frac{mL^3}{3}$ .

(Refer Slide Time: 12:57)

ii) Moment of torsional spring

$$= -K_t \theta$$

iii) Deflection of linear spring  $= L \sin \theta$

$$\text{Force} = -KL \sin \theta$$

$$\text{Moment about axis of rotation} = -KL^2 \sin \theta$$

The rigid rod is in balance under the action of these 3 moments. Therefore, the sum of these moments will be zero, i.e.,

Moment of torsional spring is minus  $K_t$  times theta. Deflection of linear spring is actually  $L \sin \theta$ . We have the spring like this and if it gets displaced, this is theta, this is  $L \sin \theta$ . We get  $L \sin \theta$ . Therefore, force is equal to minus  $KL \sin \theta$  linear spring applies a restoring force that that is minus  $KL \sin \theta$ . Now, moment about axis of rotation is minus  $KL^2 \sin \theta$ . The rigid rod is in balance under the action of these three moments: that is moment of torsional spring, deflection of linear moment due to a linear spring and the inertia moment. Therefore, the sum of these moments will be 0, because there is no externally applied load.

(Refer Slide Time: 14:08)

$$\frac{mL^3}{3}\ddot{\theta} + K_t\theta + KL^2\theta = 0$$

**This is a linear equation.**

**Rewriting it,**

$$\frac{mL^3}{3}\ddot{\theta} + (K_t + KL^2)\theta = 0$$

$\downarrow$        $\downarrow$   
N-m       $\frac{N}{m}$  m<sup>2</sup>

That is mL cube by 3 theta double dot plus K<sub>t</sub> times theta plus KL square theta equal to 0. This is a linear equation. That means, if alpha is a solution of this and beta is another solution, then c times alpha plus d times beta is also another solution. Now, rewriting it, we can say mL cube by 3 theta double dot plus K<sub>t</sub> plus KL square theta. K<sub>t</sub> is the torsional spring constant. Therefore, its unit is Newton meter. This is Newton per meter into L square is Newton square. So, dimensions match Newton meter Newton theta equal to 0.

(Refer Slide Time: 15:07)

**Comparing it with the equation**

$$m\ddot{x} + Kx = 0$$

**We can straightway write the expression for natural frequency as,**

$$\omega = \sqrt{\frac{3(K_t + KL^2)}{mL^2}}$$

**Unit of torsion spring constant  $K_t$  is N-m.**

Let us compare it with the equation  $m\ddot{x} + Kx = 0$ . We already have solved this equation, why do we solve this again? Only thing is that it is  $m$ . Instead of  $m$ , I will put  $mL$  cube by 3. Instead of  $K$ , I will put  $K_t$  plus  $KL$  square. We can straightway get the expression for natural frequency,  $\omega$  under root  $K$  by  $m$ . Sameway,  $\omega$  under root  $3 K_t$  plus  $KL$  square divided by  $mL$  square. Unit of torsion spring constant  $K_t$  is Newton meter. So,  $\omega$  is equal to  $K_t$  plus  $KL$  square divided by  $mL$  square.

Of course,  $K$  is equal to 0; that means, spring is just supported at one end by torsional spring, but the other end is free. In that case,  $\omega$  will be under root of  $3 K_t$  divided by  $mL$  square. Similarly, if there is no torsional spring that means there this is fixed but then  $K_t$  is equal to 0 and it is supported on this spring. If  $K$  is there then it will be  $3 Q K$  under root  $m$ .

(Refer Slide Time: 16:56)

Next, we will study the vibration of torsional system shown in this figure. Here, what happens in this? There is a rod and with this rod, you attach a disc. If you twist the disc, this rod also gets twisted, but this is duly fixed. That means, all cross sections rotate with respect to each other. Therefore, restoring moment is developed and that expression is given,  $K_t$ . Now, that can be measured experimentally also. You give a small displacement, angular displacement  $\theta$  then see how much torque is developed and then  $K_t$  will be torque divided by  $\theta$ .

(Refer Slide Time: 18:00)

Consider a disc having a moment of inertia  $I$  mounted at the end of a shaft without weight and having a torsional spring constant  $K_t$ , where

$$K_t = \frac{T}{\theta}$$

$K_t$  is the torque required to produce a unit angular deflection  $\theta$  in the disc.

Considering the disc as a free body,

Torque acting on the disc are

Inertia torque  $= -I\ddot{\theta}$

In this system, if the moment of inertia of the disc is  $I$  and it is mounted at the end of shaft without weight; that means, weight of the shaft is negligible compared to the weight of the disc and having a torsional spring constant  $K_t$ , where  $K_t$  is equal to  $T$  divided by  $\theta$ . That is  $K_t$  is the torque required to produce unit angular deflection  $\theta$  in the disc. We measure  $\theta$  in terms of the radian. Consider the disc as a free body. Torque acting on the disc or inertia torque which is equal to minus  $I$   $\theta$  double dot.

(Refer Slide Time: 18:57)

Restoring torque  $= K_t \ddot{\theta}$

The disc is in balance under the action of these torques. Hence,

$$-I \ddot{\theta} - K_t \ddot{\theta} = 0$$

or,

$$\ddot{\theta} + \frac{K_t}{I} \theta = 0$$
$$m \ddot{x} + k x = 0$$

Restoring torque is  $K_t \theta$ . By D'Alembert's principle the rod has to be balanced under the action of these two forces. Therefore, minus  $I \ddot{\theta}$  minus  $K_t \ddot{\theta}$  equal to 0, or  $\ddot{\theta} + \frac{K_t}{I} \theta = 0$ . Therefore, this is natural frequency. You can compare this expression with  $m \ddot{x} + k x = 0$ .

(Refer Slide Time: 19:43)

Comparing it with the equation of simple spring-mass system equation, the natural frequency is obtained as

$$\omega_n = \sqrt{\frac{K_t}{I}} = \sqrt{\frac{N-m}{kg \cdot m^2}} = \sqrt{\frac{kg \cdot m}{s^2 \cdot kg \cdot m^2}} = \frac{1}{s}$$

The general solution of this system is given as follows:

$$\theta = A \cos \sqrt{\frac{K_t}{I}} t + B \sin \sqrt{\frac{K_t}{I}} t$$

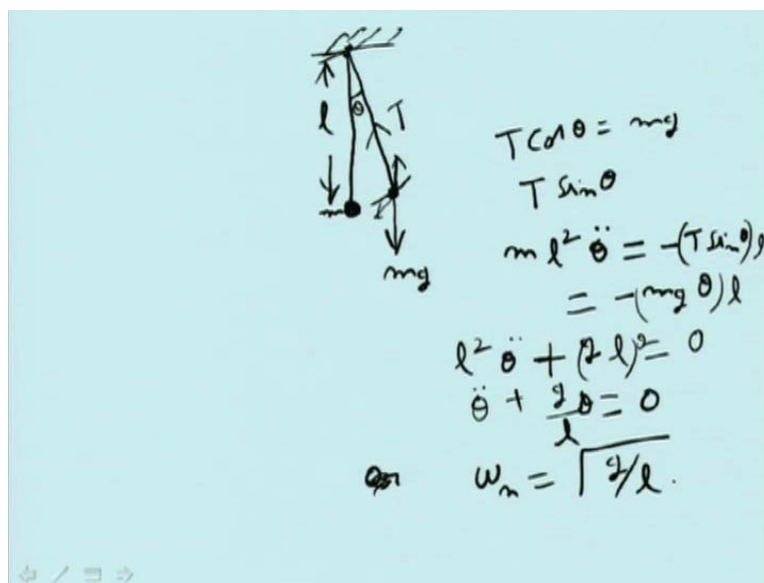

where constants  $A$  and  $B$  can be found from the initial conditions.

Therefore,  $\omega_n$  is natural frequency and is obtained.  $\omega_n$  is equal to under root  $K_t$  by  $I$ .  $K_t$  has the unit of Newton meter. Let us see the units here; Newton meter kg meter square and Newton is kg meter per second square. So, you have second square then one meter was already there, meter meter square. So, meter meter gets cancelled it becomes and this is kg. So, you get 1 by s. So,  $\omega_n$  means its unit is second inverse.

General solution of this system is given as theta is equal to  $A \cos \sqrt{K_t/I} t + B \sin \sqrt{K_t/I} t$ , where constants A and B can be found from the initial conditions. You can have different type of initial conditions. At the starting, the displacement is 0, or you can have the condition at the starting. You give some definite displacement and the velocity is 0, angular velocity 0; this is how it can be done.

Now, let us discuss the case of compound pendulum. That also can be discussed. Before that, a little bit recapitulation of the simple pendulum.

(Refer Slide Time: 21:42)

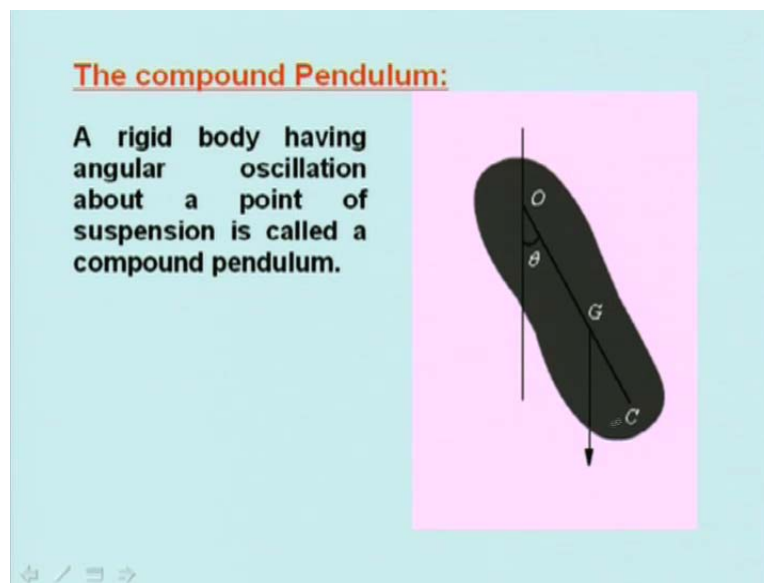

Simple pendulum consists of a string. With that, you attach a small ball. It can be treated as particle. The entire mass is concentrated here and this is  $l$ . If you displace it here, there is no spring here, but if you displace it there, its potential energy rises and gravity tries to pull it to another lowest position. So, at this moment, there is a gravitational pull that is  $mg$  and then you

have got tension. If this angle is  $\theta$  then  $T \cos \theta$  is equal to  $2mg$  and  $T \sin \theta$  will be the component in this direction.  $T \sin \theta$ ,  $T$  vertical component balance and another component is  $T \sin \theta$  which is like this. So,  $T \sin \theta$ .

If we take the moment about this point, then mass  $m$ , moment of inertia  $ml^2$   $\ddot{\theta}$  is equal to minus  $T \sin \theta$ . If we assume that  $\theta$  is very small, in that case,  $T$  will be equal to  $mg$  and  $\sin \theta$  will be  $\theta$ . Therefore, this becomes minus  $mg$  into  $\theta$ . Therefore,  $l^2 \ddot{\theta} + g$  by  $l$   $\theta = 0$ . This is minus  $T \sin \theta$ . Here, I have to multiply by length. Then, it will become this moment; this is restoring moment  $l$ . So,  $lg \theta$  is equal to 0.

Here, we get  $\ddot{\theta} + \frac{g}{l} \theta = 0$ , or here this system comparing with  $m \ddot{x} + kx = 0$ , we get  $\omega_n$  is equal to  $\sqrt{\frac{g}{l}}$ . Therefore, assumption involved here is that  $\theta$  is very very small. That is why, we could write  $T \cos \theta$  is equal to  $2mg$  and we will be able to get the simple harmonic motion.

(Refer Slide Time: 24:56)

Discussing about compound pendulum, in compound pendulum, mass is not concentrated at one point. In fact, it is distributed. This is the compound pendulum, shown. A rigid body having angular oscillation about a point of suspension is called a compound pendulum. Here, the mass acts through the center of gravity.

(Refer Slide Time: 25:15)

Let  $G$  be the center of gravity and  $O$  the point of suspension. Let  $I_0$  be moment of inertia of the body about  $O$ .

If  $OG$  is displaced by an angle  $\theta$ ,  
restoring torque  $= -W(OG)\theta$

where  $\theta$  is assumed to be small.

Hence,  $I_0 \ddot{\theta} = -W(OG)\theta$

Let  $G$  be the center of gravity and  $O$  the point of suspension. If  $I_0$  is the moment of inertia of the body about  $O$ , you have a pendulum like this; in this case, you have to take moment of inertia about this point. This is  $O$  and this point is  $G$ ,  $G$  is the mass. If  $G$  gets displaced by an angle  $\theta$  then you get restoring torque, minus  $W$  times  $OG$   $\theta$  because angle is small. So, here you have  $W$  and this point gets displaced. This weight is there and this gets displaced by this one, so it is like this.

This rises here. Therefore, you get a restoring torque as  $W$  times  $OG$   $\theta$ , just like you have got in simple pendulum.  $\theta$  is assumed to be small. Hence,  $I \ddot{\theta}$  is equal to minus  $W OG \theta$ , where  $I$  is basically about  $I_0$ ; that means, it is about a point  $O$  which is suspended here.

(Refer Slide Time: 27:03)

where  $I$  is the moment of inertia of the pendulum about  $O$ .

Thus,

$$I_g \ddot{\theta} + W(OG)\theta = 0$$

Comparing it with  $m\ddot{x} + kx = 0$ , we see that

$$\omega_x = \sqrt{\frac{W(OG)}{I_g}} = \sqrt{\frac{W(OG)}{\frac{W}{g}k^2}} = \sqrt{\frac{(OG)g}{k^2}}$$

Therefore,  $I$  is the moment of inertia of the pendulum about  $O$ . Thus,  $I_0 \theta$  double dot plus  $W OG \theta$  equal to 0. Again, compare it with  $m x$  double dot plus  $kx$  is equal to 0. We see that  $\omega$  comes out to be  $\omega_{\text{natural}} W OG$  this is  $I_0 W OG$  and this can be written as  $W$  by  $g$ .  $W$  by  $g$  is basically mass times  $k$  square, where  $k$  is the radius of gyration. This is radius of gyration about point  $O$ . This is equal to  $OG$  times  $g$  divided by  $k$  square.

(Refer Slide Time: 27:57)

where  $k$  is the radius of gyration about  $O$ .

We know that the natural frequency of a simple pendulum is  $\sqrt{\frac{g}{l}}$ , Comparing this with the natural

frequency of the compound pendulum, we can say that the effective length  $l_e$  of the compound pendulum is given by,

$$l_e = \frac{k^2}{OG}$$

We know that the natural frequency of a simple pendulum is square root  $g$  by  $l$ . Comparing this with the natural frequency of the compound pendulum, we can say that the effective length  $l_e$  of the compound pendulum is given by  $l_e$  is equal to  $k^2$  square by  $OG$ , because in this expression, this is compared with under root  $g$   $l_e$ . Therefore,  $l_e$  square  $l_e$  is  $k^2$  square by  $OG$ .

(Refer Slide Time: 28:42)

**In this expression,**

$$k^2 = k_G^2 + OG^2$$

**where  $k_G$  is the radius of gyration about  $G$ .**

**Therefore,**

$$l_e = \frac{k_G^2 + OG^2}{OG} = \frac{k_G^2}{OG} + OG$$

**If  $OG$  is extended up to  $C$ , such that**

In this expression,  $k^2$  is the radius of gyration about fixed point  $O$  which is equal to  $k_G^2$  square plus  $OG^2$  square. This comes from the parallel axis theorem.  $k^2$  is equal to  $k_G^2$  square plus  $OG^2$  square, where  $k_G$  is the radius of gyration about  $G$ . Therefore,  $l_e$  is equal to  $k_G^2$  square plus  $OG^2$  square divided by  $OG$ . This comes out to be  $k_G^2$  square by  $OG$  plus  $OG$ . If you have compound pendulum like this and this point is extended up to  $C$ , some point  $C$ , where  $OC$  is equal to  $OG$  plus  $k_G^2$  square by  $OG$ ; that means,  $GC$  is equal to  $L$  by  $OG$ .

(Refer Slide Time: 30:05)

$$GC = \frac{k_G^2}{OG}$$

then **C** is called the center of percussion and

$$I_e = OC$$

i.e., the equivalent length is equal to the distance from fixed point O to center of percussion.

GC is equal to  $k_G$  square by OG. Then C is called the center of percussion. We have already discussed about center of percussion in the previous lecture.  $I_e$  comes out to be OC; that is, the equivalent length is equal to the distance from fixed point O to center of percussion. Center of percussion is the point, about, if you strike at that point then no reaction is developed in the direction of the striking of that force.

That means, if you know the center of percussion of one body then you can apply a tangential force. Here, it will not produce any reaction in this direction. We have discussed this in one of the previous lectures. Now, we will discuss about the other problem.

(Refer Slide Time: 31:19)

We discuss bifilar suspension. If a body is suspended from two strings and given an angular displacement  $\theta$  about the vertical axis and released, it will execute torsional vibration. Such an arrangement is called bifilar suspension. I am drawing the figure here. A bifilar suspension will be like this and it is a disc type of thing. It is how, a string is attached here.

This is the G and this is C, this is D then you have l. This arrangement is called bifilar suspension. It is suspending like this. If I twist the disc little bit, if I give the twist here then a restoring moment is developed. Why? Because these strings which are vertical will also be twisted by the same amount and they will become inclined. The inclined strings will provide a vertical as well as horizontal component. Vertical component will support the weight of the disc, whereas the horizontal component will provide the restoring torque.

(Refer Slide Time: 33:22)

If we give a small angular displacement  $\theta$  to the disc in its plane, the strings holding the disk will become inclined. See this after pressing the CLICK button. The inclined strings will provide horizontal component of the force due to their tensions.

The tension in strings attached at **C** and **D** respectively are given by

$$T_c = \frac{W(GD)}{CD} \quad T_d = \frac{W(GC)}{CD}$$

If we give a small angular displacement  $\theta$  to the disc in its plane, the string holding the disc will become inclined. Now, inclined strings will provide horizontal component of the force due to their tensions. The tension in the strings attached at C and D respectively will be like this: If it is C and it is D, in C it will be  $W \cdot GD$  divided by  $CD$ . Then, this is  $W \cdot GC$  divided by  $CD$ . This is  $T_d$  and this is  $T_c \cdot WC$ . This is because angle  $\theta$  will become like this. If you say that  $\theta$  rotates little bit, so that is  $l$ . Suppose, you have attached a string like this and this thing here, that  $G$  and this becomes  $\theta$ .

This will be equal to  $r \theta$ , suppose you give that displacement  $r \theta$ . This is the height and this is  $l$ . It is basically,  $r \theta$  and  $\phi$  is equal to  $r \theta$  divided by  $l$ . You will have  $r \theta$  divided by  $l$  type of thing. So,  $W \cdot GD$  by  $T_c$  is equal to this  $l$ .

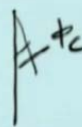

(Refer Slide Time: 35:26)

**For small angle of rotation,**

$$(CG)\theta = l\phi_c$$

$$(GD)\theta = l\phi_d$$

**where  $l$  is the length of the string and angles have shown in the figure. From the above equations, we obtain,**

$$\phi_c = \frac{(CG)\theta}{l}, \phi_d = \frac{(GD)\theta}{l}$$

For a small angle of rotation, we can always write, CG times theta is equal to  $l\phi_c$ . If angular displacement  $\phi_c$  and GD times theta is equal to  $l\phi_d$ , where  $l$  is the length of the string and the angles are like this, here this is  $\phi_c$ , like that  $\phi_d$ . Therefore  $\phi_c$  is equal to CG times theta divided by  $l$  and  $\phi_d$  is equal to GD times theta divided by  $l$ .

(Refer Slide Time: 36:18)

**The horizontal component of forces due to two strings are**

$$T_c\phi_c = T_d\phi_d = \frac{(GD)(CG)\theta}{(CD)l}$$

**(Note: Only for small  $\theta$ ,  $T_c\phi_c$  and  $T_d\phi_d$  are components of tension in the horizontal direction.)**  
**Taking moment about the center of disc G, we obtain the restoring moment,**

$$\text{Restoring moment} = T_c\phi_c (CG) + T_d\phi_d (GD)$$

Then, the horizontal component of forces due to two strings will be  $T_c \phi_c$  and that same thing will be  $T_d \phi_d$  and these will be  $GD$  times  $CG$  theta  $CD$  by  $l$ . Only for the small theta,  $T_c \phi_c$  and  $T_d \phi_d$  are components of tension in the horizontal direction. Now, taking moment about the center of disc  $G$ , we obtain the restoring moment. So, restoring moment will be  $T_c$  into  $\phi_c$  multiplied by  $CG$  plus  $T_d$  into  $\phi_d$  multiplied by  $GD$ .

(Refer Slide Time: 37:14)

$$= T_c \phi_c (CG + GD) = T_c \phi_c (CD)$$

$$\text{Restoring moment} = \frac{W (GD)(CG) \theta}{l}$$

Therefore, the equation of motion is given by,

$$I_G \ddot{\theta} + \frac{W (GD)(CG) \theta}{l} = 0$$

This will be equal to  $T_c$  times  $\phi_c$   $CG$  plus  $GD$ , or it will be  $T_c$  times  $\phi_c$  multiplied by  $CD$ , where  $CD$  is the distance between these two points. Therefore, the equation of motion is given by  $I_G$  theta double dot plus  $W$   $GD$  into  $CG$  theta divided by  $l$  into  $0$ . This is  $I_G$  theta double dot plus  $W$  times  $GD$   $CG$  theta  $l$ .

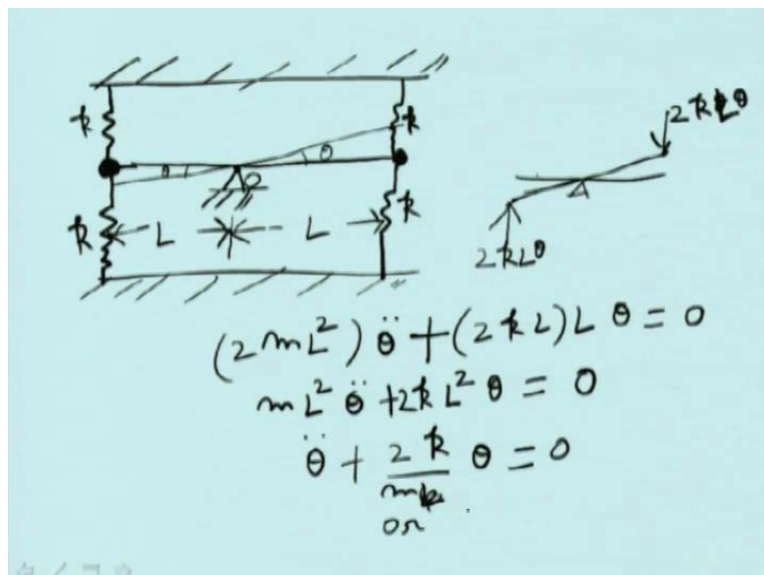

(Refer Slide Time: 38:12)

Comparing it with the simple spring-mass system,  
the natural frequency is given by

$$\omega_n = \sqrt{\frac{W(GD)(CG)}{I_G}}$$

Comparing it with the simple spring-mass system, the natural frequency is given by  $\omega_n$  is equal to  $W GD CG$  and divided by  $I_G$ .  $I_G$  is the length of the spring. So, this way, we can find out the frequency, natural frequency of this suspension also. Now, I will be doing some simple problems for the system.

(Refer Slide Time: 39:00)

Let us try to solve some other problems. If there is a pivot here and one rod is fixed. At the end of the rod, I took two small balls and their masses maybe  $m$ . Then, here you attach, **this is the upper that force one right and** here another fixed wall and here you attach a spring like this. Assume that, this figure I have drawn is in a horizontal plane. So, gravity effects are not there. It is in a horizontal plane, so, it vibrates.

Now, what will happen? When we rotate it about this hinge point then restoring moment is developed. There is spring  $k$ , this spring constant is  $k$ . This is also  $k$  this is also  $k$ . If you give a small angle  $\theta$  then there is a rotation. This is  $l$  and this will be  $l$ .

If you give a small rotation  $\theta$ , this point, this ball gets upward by an amount,  $l \theta$ . This spring gets compressed by amount  $k \theta$ ; another spring gets stressed by  $k \theta$ . Therefore, they apply the forces and this will be  $k \theta$ . So, total force coming on this ball will be basically  $2k \theta$ . Why because, this spring gets compressed by about  $l \theta$ ;  $kl \theta$ . This is  $kl \theta$ .

Another also gets stressed by  $kL \theta$ . Both are putting the forces in the same direction. They get added up and this is  $2 kL \theta$ . In fact, these two springs are in parallel. Similarly, this side also the spring gets compressed and this gets stretched. Compressed spring puts force like this and stressed spring tries to pull it upward. Therefore, again, this force is  $2 kL \theta$ . This is  $2 kL \theta$ . Then take the moment about the pivot point,  $O$ .

We have to see, what is the total mass moment of inertia about point  $O$ . This is  $mL^2$  plus  $mL^2$ ; that means  $2 mL^2$ . You apply that equation  $2mL^2 \theta$  into  $\theta$ . Inertia torque is equal to plus  $2 kL \theta$ . This is actually, a couple  $2kL \theta$   $2kL \theta$  acting there and distance between them is  $2L$ . So,  $2kL \theta$  into  $L$  that means  $2kL^2 \theta$ .  $L \theta$  equal to  $0$  that means  $mL^2 \ddot{\theta}$  plus  $kL^2 \theta$  equal to  $0$ , or  $\theta$  square gets cancelled.

Therefore,  $\ddot{\theta}$  equal to  $\theta$  plus  $2km$   $2 kL \theta$   $2kL^2 \theta$  equal to  $0$  or  $\omega$  of this system is given by under root  $2k$  by  $m$ . This is how you know that this rigid rod will vibrate. Let us try to do another problem on this system.

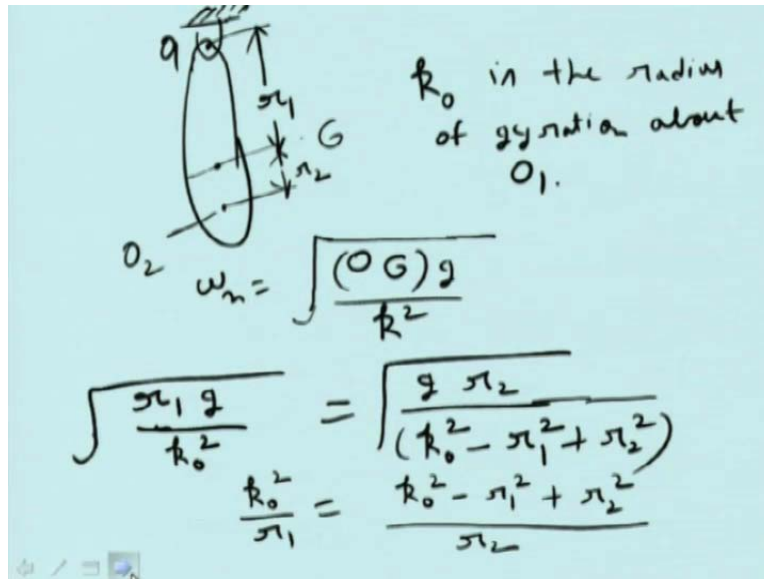

(Refer Slide Time: 44:53)

Here, this is rod. If I take a thin lamina and if there is a hinge and you suspend it like this and if it starts vibrating about AA, give a small rotation about AA and this length is b, then we are interested to know what is the frequency of oscillation or what is the time period. When it starts oscillation about axis AA and we have to find out the moment of inertia about axis AA. That is given by  $mb^2/3$  into  $\ddot{\theta}$ . This is about this one  $\ddot{\theta}$   $mb^2/3$  is the moment of inertia about AA and this gets displaced. Its cg is at a distance of  $b/2$  when it gets displaced by an angle  $\theta$  then you get restoring torque equal to minus  $b/2 mg \theta$ .

Therefore, this becomes,  $b^2/3 \ddot{\theta} + b/2 g \theta - mg \theta$  into  $b/2$  is the distance to the torque, because if I make this side view, this gets you  $\theta$ . So, what happens, this is  $b/2$ ; this distance is  $b/2$  and this mass,  $mg$ . So, that one component is basically it is a component along this  $mg$  that is tension. So, tension  $t$  is equal to  $mg$  for a small angle and its component  $mg \sin \theta$  you get is equal to 0 and therefore,  $\omega$  comes out to be equal to  $\sqrt{3/2 g/b}$ . So, we get this type of thing;  $\omega$  is equal to  $\sqrt{3/2 g/b}$  and time period  $T$  comes out to be  $2\pi/\omega$  that means  $2\pi \sqrt{2/3 b/g}$ . This is the solution of this problem. This is how it can be done.

(Refer Slide Time: 49:08)

Now, one problem on compound pendulum. A compound pendulum is shown here. This point is  $O_1$ , this point is  $G$ , this point is  $r_1$  and from here to here, another one point I have marked is  $O_2$  and this distance is  $r_2$ . In this problem, it is given that  $k$  or  $k_0$  is the radius of gyration about  $O_1$ . It is given that if this compound pendulum is hinged at  $O_1$  and then oscillated, you get certain time period. If the compound pendulum is now hinged at  $O_2$  and provided oscillation, then you get time period. Both the time periods are equal.

In that case, what is the relation between the radius of gyration  $k$ ,  $k_0$ , where  $k_0$  is the radius of gyration about point  $O_1$  and  $r_1$   $r_2$ . Let us try to solve this problem. Go back to the compound pendulum slide.

(Refer Slide Time: 51:17)

where  $k$  is the radius of gyration about  $O$ .

We know that the natural frequency of a simple pendulum is  $\sqrt{\frac{g}{l}}$ , Comparing this with the natural frequency of the compound pendulum, we can say that the effective length  $l_e$  of the compound pendulum is given by,

$$l_e = \frac{k^2}{OG}$$

$l_e$  is equal to  $k$  square divided by  $OG$ . Effective length of the compound pendulum is given by  $k$  square by  $OG$ .

(Refer Slide Time: 51:34)

where  $I$  is the moment of inertia of the pendulum about  $O$ .

Thus,

$$I_o \ddot{\theta} + W(OG)\theta = 0$$

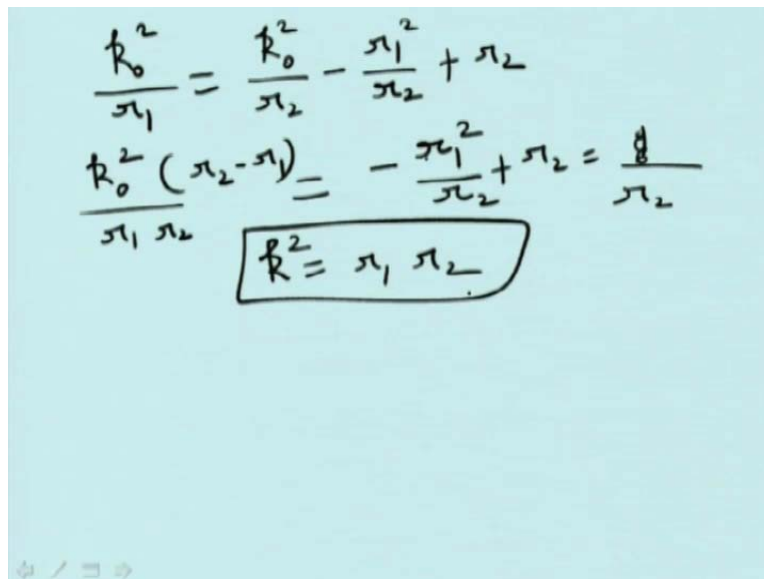

Comparing it with  $m\ddot{x} + kx = 0$ , we see that

$$\omega_n = \sqrt{\frac{W(OG)}{I_o}} = \sqrt{\frac{W(OG)}{\frac{W}{g}k^2}} = \sqrt{\frac{(OG)g}{k^2}} = \sqrt{\frac{g}{l_e}}$$

$OG$  into  $G$  divided by  $k$  square. The same type of thing we have to put here. So, this is  $2k$ . Therefore, time period of the compound pendulum is same. Therefore, angular omega will be same. We will be writing that as,  $k$  square. Now, let me use the expression for this thing.

Equivalent length is  $k^2$  OG  $\omega_n$  is equal to OG. We had OG multiplied by  $g$ . This is  $k^2$  square, that same thing here. For the first case, it is  $r_1$  multiplied by  $g$ ;  $r_1$  multiplied by  $g$  and then divide by  $k^2$  square  $k_0^2$  square is equal to, I will be writing  $k_0^2$  is  $r_2 g g r_2$  and this is  $k_0^2$  square. I am suspending about  $O_2$ . Therefore, this will be  $k_0^2$  square minus  $r_1$  square plus  $r_2$  square, because the radius of gyration about  $g$  is now  $k_0^2$  square minus  $r_1$  square plus I am putting that  $r_2$  square, because I have to find out radius of gyration about this one. Therefore, we get a relation basically  $k_0^2$  square by  $r_1$ . Reverse this; so, this must be equal to  $k_0^2$  square minus  $r_1$  square plus  $r_2$  square divided by divided by  $r_2$ .

(Refer Slide Time: 54:36)

$$\frac{k_0^2}{r_1} = \frac{k_0^2}{r_2} - \frac{r_1^2}{r_2} + r_2$$

$$\frac{k_0^2 (r_2 - r_1)}{r_1 r_2} = -\frac{r_1^2}{r_2} + r_2 = \frac{g}{r_2}$$

$$\boxed{k^2 = r_1 r_2}$$

This can be simplified as  $k_0^2$  square divided by  $r_1$  is equal to  $k_2^2$  square  $k_0^2$  square by  $r_2$  minus  $r_1$  by  $r_2$  plus  $r_2$ . This can be written as, this is minus  $r_1$  square should be dimensionally balanced to  $k_0^2$ . Therefore, this can be written as  $k_0^2$  square  $r_1 r_2$  can be taken as common. This is  $r_2$  minus  $r_1$  is equal to minus  $r_1$  by  $r_2$  minus  $r_1$  square by  $r_2$  plus  $r_2$ , or you take 1 by  $r_2$  common and you take  $r_2$  common here also. This is 1 by  $r_2$  and this will be minus  $r_1$  square by  $r_2$  this is  $r_2$  by  $r_1$ . When you simplify this expression, I am now skipping 1 or 2 steps.

Then you should get,  $k^2$  square is equal to  $r_1 r_2$  which is the required relation. So,  $k^2$  square is equal to  $r_1 r_2$ . You have been able to solve this problem also. So, this is what happens about this.

In this lecture, let us summarize what we have talked. We have seen that when a rigid body is constrained to move in a particular way so that its position can be described by a single coordinate, it may be the angular position  $\theta$ , then it becomes a single degree of freedom problem and it can be solved in the same way as the spring-mass system. The differential equation remains basically same. Therefore, mathematics required is basically same. So, we have discussed about this type of motion.

(Refer Slide Time: 58:02)

First we took up the case in which a torsional spring was put. After that, we have discussed the case of a disc suspended from a rod or shaft. When we twist it, the shaft gets twisted and due to elasticity, it tries to come back to its position. Therefore, it has some equivalent stiffness. We have discussed that case also.

Then, we have discussed about the compound pendulum problem which can also provide simple harmonic motion. However,  $\omega_n$  will be basically under root instead of  $g$  by  $l$ . This will be  $g$  by  $l_e$ , where  $l_e$  is the equivalent length which is the distance from a fixed point up to the center of percussion. This is what we have discussed. Equivalent length is equal to the distance from fixed point  $O$  to center of percussion. This we have discussed.

Then, we have done simple problem like one problem we did bifilar suspension. There is a disc which is suspended by the two strings and then it is given some twisting. So, in that case, what happens? That type of motion we have studied.

In the next lecture, we will discuss more about the vibration of rigid bodies. We will first start our discussion with a trifilar suspension where there is a same disc, but it is now fixed from a ceiling by three strings. So, one string may be this, another may be here and the third is here like that. So, this is fixed by this thing and that is called trifilar suspension. We will start our discussion from this in the next lecture.
