Mathematical Preliminaries – 2
Lecture – 06-08
Linearization, Directional Derivative and Tensor Analysis

So, welcome to the next module of this course, which will be final module on mathematical preliminaries ok. So, there are three lectures planned in this module and as you can see these lectures will cover very important topics of Linearization, Directional Derivative and Tensor Analysis and also we will devote some time on working out some examples, so that you should be able to understand the theory much better.

(Refer Slide Time: 01:18)

Contents	2
1. Linearization and Directional Derivative	
2. Tensor Analysis	
3. Worked out Examples	

So, this is the content of this module. The first one is linearization and directional derivative. Followed by tensor analysis and then finally, we will look into the worked out examples to help you with the theory part.

(Refer Slide Time: 01:37)

1. Linearization and Directional Derivative 3

- Nonlinear problems invariably result in nonlinear equations.
- To solve the nonlinear equations they have to be linearized.
- Then, these linearized equations are solved iteratively using a suitable technique until the solution is solved.
- One of the most popular technique is the Newton-Raphson method.
- To get accurate solutions a correct linearization is "must"

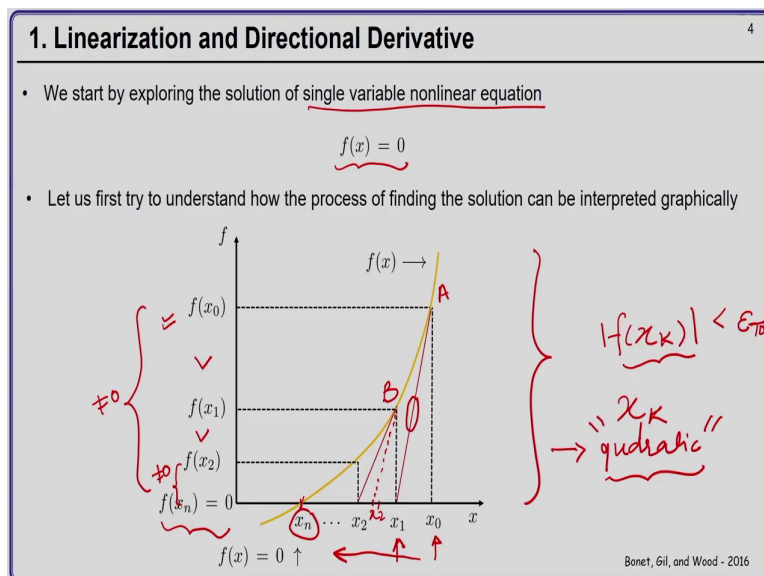

So, coming to the first topic, so, these non-linear problems will invariably result in non-linear equations ok. And these non-linear equations have to be solved by linearizing ok. That is what I have underlined here ok this term over here which is very important is linearization ok. So, you have to linearize these non-linear equations ok. And then once you have linearize these non-linear equations you have to solve these equations iteratively using a suitable technique and you have to do this until you have found out the solution ok.

So, one of the most popular technique is Newton Raphson method. Obviously, there are other techniques to solve non-linear equations, where you need not use any iteration. You can just

keep on solving the equations. So, you linearize and then you can without employing Newton-Raphson method you can just solve that, but we will concentrate on method which use iterations to solve the system of non-linear equations and we will specifically focus only on Newton-Raphson method, ok.

So, to get the accurate solution for your system of non-linear equation you have to have a very correct linearization, ok. So, correct linearization is must for getting accurate solutions. What it means is if you do not linearize properly, it might happen that you might get a solution, but it will take much longer to get the solution; longer means in terms of the computational time or in the worst case you may not get any solution at all ok. So, it has. So, it is very essential that a correct linearization is carried out for Newton-Raphson method to work nicely, ok.

(Refer Slide Time: 04:20).

So, before we begin with system of non-linear equation, let us first start with exploring the solution of single variable non-linear equation, which is we have written here; $f(x) = 0$, x is a variable ok. Now, our equation is $f(x)$ and now we want to solve this equation. What it means is we want to get the roots of this equation ok. So, we want to solve for those value $f(x)$, for which $f(x)$ is equal to 0. So, before starting the mathematical details we first look into take graphical interpretation of how this solution for a non-linear equation is obtained using Newton-Raphson method.

So, as you can see here we have plotted for general function $f(x)$ which is shown here as this yellow line and the point at which this function cuts the x axis here that is where your solution lies ok. So, $f(x) = 0$ is this point where the yellow curve intersects the x axis ok. So, now, to solve this equation the first thing that one should have is an initial guess ok. Initial guess means you do not have a idea about the solution, but you have some idea in which arrange the solution will lie, ok.

So, you have some idea of the solution. So, say x_0 , say this is the initial guess that you start with and then as you know x_0 , you know the value of $f(x_0)$ ok. Now, you can see $f(x_0)$ is not equal to 0 ok; so that means, x_0 is not the solution. So, what you do? What we do next is we make a tangent at this point. Let us call this point as A , ok. So, this red line is a tangent to the yellow curve at point A and then we know the slope of the line red line ok that is the derivative ok. Derivative of the curve at x_0 that is $f'(x_0)$ and now we know this point also, the coordinates of this point.

So, we know the equation of red line and using that we can find out where this red line cuts the x axis. Let us say this point is x_1 ok. Now, again we can compute the value of the function at x_1 ok. Say this is the value of function $f(x_1)$, ok. Now, we notice that although the value of the function is still not 0, but this value of the function $f(x_1)$ is less than $f(x_0)$, ok which means our new approximation of the solution x_1 has reduce the value of the function ok. So, we are approaching in the correct direction.

So, now, since we still not reached 0 then what we do? We follow the previous procedure. At say this point is B, now again at point B we make a tangent ok. And knowing the slope of the red line and the coordinates of point B, we can compute the intersection of the red line with the x axis. Let us say it cuts at value x equal to x_2 .

Now, again I can check the value of the function f of x_2 ok. So, I can check the value of the function f of x_2 and you can see here that again f of x_2 is not equal to 0, but obviously, f of x_2 the magnitude or the value is less than f of x_1 ok. So, again we are reducing the value of the function ok. So, so on we keep on repeating this. So, we go to x_3 x_4 and we keep on doing this till we reach our point of interest which is this solution ok; f at say n th step we read the solution where f of x_n is equal to 0 ok.

So, as soon as we reach f of x_n equal to 0, we know that x_n is our solution ok. So, that this graphical illustration shows how the Newton-Raphson procedure actually works ok. Now, the thing to notice when you are applying Newton-Raphson procedure over computer you may not actually get 0, ok. You may get a very small number maybe 10^{-9} , 10^{-10} or something like that, but we will not actually get 0 ok.

So, we have certain criteria. We say that whenever say f of x_k becomes less than say some value ϵ tol; tol is for tolerance ok. So, when the magnitude of the function at k -th point x_k is less than our specified tolerance ok, so, this tolerance has to be given by the user who is using this procedure and when whenever this value becomes less than this tolerance we say that our solution is x_k ok.

Now, the important point to note about this Newton-Raphson procedure is if you are nearer to the root, as you go nearer and nearer to the root that is as you approach the solution the rate at which the convergence is achieved is quadratic ok. So, if you are far away from the root say x_0 was far away from the solution that we were seeking then initially, the convergence will never be quadratic, but it might be linear what is called linear ok. But, as we approach towards the solution the last few steps of Newton-Raphson will actually show you that it converges what is called quadratically, ok.

So, that is one of the features of Newton-Raphson procedure. And if you have computed your tangents that is slope of this red line if you computed this tangent accurately then this quadratic convergence is guaranteed. However, you will notice that even if say for example, at point B, you did not calculate the tangent accurately and say you calculated something like this then instead of reaching x_2 you would have reached a point x_2 dash, but still you have moved closer to the root or the solution x_n , ok.

So, even if you have a wrong tangent it does not mean that you will not get a solution ok. You might still be able to get the solution, but your, the rate at which you will approach the solution will not be quadratic. You will take much more number of steps to achieve the solution that you have to remember. So, the fact that I mentioned in the previous slide, so, to correct to get the correct and accurate solution and ensure to ensure the quadratic convergence of Newton-Raphson procedure, it is necessary that you calculate the tangents of this Newton-Raphson procedure very accurately, so that I mean it means the linearization has been done very accurately ok.

(Refer Slide Time: 13:34)

5

1. Linearization and Directional Derivative

- Next, we start to set up the mathematical framework for the graphical procedure just discussed
- We start by expanding the function $f(x)$ using Taylor's series about the initial guess x_0 as

$$\Rightarrow f(x) = f(x_0) + \frac{df}{dx}\bigg|_{x=x_0} (x - x_0) + \frac{1}{2} \frac{d^2f}{dx^2}\bigg|_{x=x_0} (x - x_0)^2 + \dots \quad \text{Eq. (1)}$$

denoting

$$u = (x - x_0) \Rightarrow x = x_0 + u$$

and using this in the Taylor series expansion Eq. (1), we can rewrite Eq. (1) as

$$\Rightarrow f(x_0 + u) = f(x_0) + \frac{df}{dx}\bigg|_{x=x_0} u + \frac{1}{2} \frac{d^2f}{dx^2}\bigg|_{x=x_0} u^2 + \dots \quad \text{Eq. (2)}$$

Bonet, Gil, and Wood - 2016

Next, we move to the mathematical framework for the graphical procedure that we have just discussed ok. So, now, what we do? We start by expanding this function f of x using Taylor series about our initial guess x_0 , ok. So, equation 1 here shows that Taylor series expansion of the function about point x_0 ok. So, f of x is equal to f of x_0 plus d of df by dx evaluated at x equal to x_0 into x minus x_0 plus 1 by 2 d^2 f by dx^2 evaluated at x equal to x_0 into x minus x_0 the whole square plus and so on.

You will have quadratic curve you have you will have quartic term like this ok. Now, if you denote x minus x_0 as u , which means x is x_0 plus u and if we use this in equation 1 then we can rewrite equation 1 as f of x_0 plus u equal to f of x_0 plus d f by dx evaluated at x equal to x_0 into u plus 1 by 2 d^2 f by dx^2 x equal to x_0 , evaluated at x equal to x_0 into u

square plus higher order terms ok. Now, the question you might raise at this point or your doubt might come why we have chosen this symbol u.

Because in undergraduate books on numerical analysis mostly this term h or the symbol h is use, but we have specifically chosen u because as we move later on in this course you will come to signify displacements ok. So, it is if we use this symbol here it is much easier to understand later because instead of this scalar u will have vector u which will be a bold. So, it is become very easy to understand much easier to understand ok.

(Refer Slide Time: 15:58).

1. Linearization and Directional Derivative 6

We then "linearize" Eq. (2) by truncating the Taylor's series at the linear term i.e. by neglecting the higher order terms to obtain the following relation

$$\checkmark f(x_0 + u) \approx f(x_0) + \left. \frac{df}{dx} \right|_{x=x_0} u + \dots \quad \text{Eq. (3)}$$

neglected

The second term on the right hand side is called the "linearized increment in $f(x)$ at x_0 "

This is generally expressed as

$$Df(x_0)[u] = \left. \frac{df}{dx} \right|_{x=x_0} u \approx f(x_0 + u) - f(x_0) \quad \text{Eq. (4)}$$

The way to compute the linearized increment is as follows

$$Df(x_0)[u] = \left. \frac{d}{d\eta} \right|_{\eta=0} f(x_0 + \eta u) \quad \text{Eq. (5)}$$

Bonet, Gil, and Wood - 2016

So, now you get this equation 2 over here. Now, what we do is we linearize equation 2 ok.

So, how do we linearize equation 2? You would have seen that the first term on the right hand side is a fix value ok. It is the value of the function at x 0. The second term, it is a linear

function in u ok. It is a linear function in u because u has a power of 1; this df by dx evaluated at x equal to x_0 is a also known value, but u is unknown for you right now. Similarly, the third term is a quadratic term where u is u square, therefore, it is a non-linear term in u square.

So, all the terms beyond this linear term are non-linear terms ok, non-linear in u they are all non-linear in u . So, to linearize what we do is we neglect the higher order terms ok; terms containing u square u cube and henceforth that we neglect in equation 2. And then what we get is the left hand side will be approximately that is why you see instead of the equal sign now we have the approximation sign. So, f of x_0 plus u will be approximately equal to f of x_0 plus df by dx evaluated at x equal to x_0 into u and all the higher order terms which were here have been neglected.

We have all neglected the higher order term ok. So, this second term were on the right hand side is what is called the linearize in increment in f of x at x_0 . So, this is the term in this bracket or this box red box is call the linearize increment in f x at x_0 . So, this term on inside the red bracket is usually denoted by D capital D f of x_0 and then there is square bracket u equal to d f by d x x equal to x_0 into u , which from the third equation is nothing, but f of x_0 plus u minus f of x_0 ok.

So, this is a standard convention which is I have written here. This is standard convention and how do you compute this d of f x_0 at square bracket u ? So, this square bracket does not mean that x_0 is multiplied by u it has a different meaning ok. So, whenever in this course we use square bracket, it does not mean you have to open up the bracket there is a special meaning for these kind of brackets, ok. So, the way you compute this linearize in increment which is this term over here is as follows ok.

So, what you do? You take a function and replace x by x_0 plus η times u ok. So, if you have your function in x , what you do? You substitute x equal to x_0 plus η times u and then what you do is take the derivative of that function with respect to η and then finally, substitute η equal to 0. Once you have done this you will get the linearize increment of f of x at x_0 , ok.

(Refer Slide Time: 19:50).

1. Linearization and Directional Derivative 7

Note that the symbol $Df(x_0)[u]$ denotes a derivative. Its is read as "directional derivative of f at x_0 in the direction u "

We can now set up the "Newton-Raphson" iterative procedure using Eq. (3) by setting the function on the left hand side evaluated at the k^{th} step to 0 i.e.

$$f(x_k) + Df(x_k)[u] = 0 \quad k = 0, 1, 2, 3, \dots \quad \text{Eq. (6)}$$

The new solution x_{k+1} is then

$$x_{k+1} = x_k + u \quad k = 0, 1, 2, 3, \dots \quad \text{Eq. (7)}$$

where

$$u = \left[-\frac{df}{dx} \Big|_{x=x_k} \right]^{-1} f(x_k) \quad \text{Eq. (8)}$$

Note: The converge is quadratic near the solution provided $Df(x_k)[u]$ is accurate.

Bonet, Gil, and Wood - 2016

So, you have to note that this symbol D of f of x_0 at u denotes a derivative and the way it is read is directional derivative of f at x_0 in the direction u , ok.

So, whenever you see this term D of f of x_0 at u ok, it is read as directional derivative of f at x_0 in the direction u . So, now, we can now set up the Newton-Raphson iterative procedure using equation 3 ok. So, what was equation 3? That was equation 3 ok. So, to set up Newton-Raphson procedure the left hand side of equation 3 is set to 0 and instead of x equal to x_0 we put x equal to x_k . So, we have f of x_k plus the directional derivative of the function at x_k evaluated in the direction u where k goes from 1; 0, 1, 2, 3, ok.

So, when k is 0 you have f of x_0 plus D of f of x_0 at direction u . When k is 1, you have f of x_1 plus D of f of x_1 in the direction u equal to 0 like so, on. And then what is x_{k+1} ? The new solution x_{k+1} will be simply $x_k + u$, where k goes from 1 to u ok. In this way you can

set up the Newton-Raphson procedure. So, what we do? We start with k equal to 0; k equal to 0 you have x_0 , ok. So, now, you compute u using this formula ok. So, this formula you can obtain from equation number 3.

So, u will be minus of df by dx evaluated at x equal to x_k raised to power minus 1 ok. So, there is a square bracket. So, let me just make it a other kind of bracket because I told square bracket will have a special meaning ok. So, you compute df by dx at x equal to x_k ok, take the negative of it, take the inverse and then multiply it by f of x_k . You will get the value of u ok. So, at k equal to 0 x_1 will be x_0 plus u then you recompute for x_2 x_3 and so hence so on and you stop when f of x_k becomes less than a tolerance value ok.

So, the important point to notice the convergence will be quadratic near the solution provided the directional derivative of the function at x_0 or say x_k is accurately computed ok. If you are computed your directional derivative accurately its guaranteed that you will converge quadratically near the solution ok.

(Refer Slide Time: 23:20).

1. Linearization and Directional Derivative 8

- Next, we move to setting up the Newton-Raphson procedure for a set of general nonlinear equations given by
$$\Rightarrow \mathcal{G}(x) = 0 \tag{Eq. (9)}$$
where the function $\mathcal{G}(x)$ can represent a system of nonlinear algebraic equations (as in FEM) or nonlinear differential equations, where the unknowns x are functions. Then, x represents a list of unknown variables or functions. Equation (9), therefore, represents the most general form of nonlinear equations.
- As in the case of single variable function case, we consider an initial guess x_0 and an increment u such that we generate a solution given by
$$x = x_0 + u \tag{Eq. (10)}$$
which will, hopefully, get us closer to the actual solution.
- Now, the problem when we try to extend the previous procedure to this general nonlinear equations given by Eq (1) is that it is not known how to take the derivative of a complicated function $\mathcal{G}(x)$.

Bonet, Gil, and Wood - 2016

Next we move towards setting up the Newton-Raphson procedure for a set of general non-linear equations, which are given by this G of x equal to 0. Now you notice instead of scalars, now, we have bold symbols. Scalars were simple non bold symbols. Now, we have bold symbols and where this function G of x may represent a system of non-linear algebraic equation as one would get in finite element method or they may represents non-linear differential equation where the unknown x can be functions, ok. So, equation 9 is very general right now. It can represent system of non-linear algebraic equations or it may also represent non-linear differential equations, ok.

So, therefore, x represents a list of unknown variables or functions. Therefore, equation 9 represents the most general form of non-linear equations ok, that is the most general form and when we go into worked out examples you will be able to see it more clearly ok. Now, we want to solve this general non-linear equation ok. So, we again as was in the case for function

or single variable we take an initial guess x_0 and we take an increment u ok. Now, we have x_0 which is bold which is some scalar and increment u which is also bold which means ok, it is a vector sorry x_0 is a vector.

So, now, we can generate a new solution x as x_0 plus u with the hope that when we do x_0 plus u ok, we will be getting closer to the solution ok. So, now, the problem right now is when we try to extend the previous procedure which we did for a single non-linear equation to this general non-linear equation given by equation 9 over here, it is not clearly known how will you take the derivative of a complicated function G of x ok.

(Refer Slide Time: 26:08)

1. Linearization and Directional Derivative 9

We now introduce a single artificial parameter η such the given nonlinear equations $\mathcal{G}(x)$ can be rewritten as a function G in η

$$G(\eta) = \mathcal{G}(x_0 + \eta u) \quad \text{Eq. (11)}$$

For example: in the one variable nonlinear function case we will have

$$G(\eta) = \mathcal{G}(x_0 + \eta u) \quad \text{Eq. (12)}$$

Next, to set up Newton-Raphson procedure, we expand Eq. (11) using Taylor's series expansion of the nonlinear function $G(\eta)$ at $x = x_0$ and setting $\eta = 0$. This gives

$$G(\eta) = G(0) + \left. \frac{dG}{d\eta} \right|_{\eta=0} \eta + \frac{1}{2} \left. \frac{d^2G}{d\eta^2} \right|_{\eta=0} \eta^2 + \dots \quad \text{Eq. (13)}$$

Bonet, Gil, and Wood - 2016

So, to do this what we do is we introduce a artificial parameter call eta ok. Remember our initial guess is x_0 and say we want to move in a direction u , arbitrary direction u that will take us closer to the solution. So, in a way we know x_0 , u is what we want to find out. So, what

we do is we rewrite our given non-linear equation G of x in terms of η as given by equation 11 ok. So, we substitute instead of x we substitute x_0 plus ηu . So, what we get is a non-linear equation solely in terms of η which is on the left hand side of equation 11, ok.

So, for one variable non-linear equation this would be like what is shown in equation 12 ok. Now, what we do is we take the Taylor series expansion of the non-linear function G of η in equation 11 at x_0 and then setting η equal to 0, ok. So, this is the Taylor series expansion of G of η about x equal to x_0 and setting. So, we; so, G of η is G of 0 plus dG by $d\eta$ evaluate η equal to 0 into η plus $\frac{1}{2} d^2 G$ by $d\eta^2$ evaluated at η equal to 0 into η^2 plus higher order term. Again you can see the second term is a linear term in η that is third term is a non-linear term in η . The first term obviously is known at η equal to 0 ok. So, η equal to 0 is basically x equal to x_0 ok.

(Refer Slide Time: 28:15)

1. Linearization and Directional Derivative 10

Introducing the definition of $G(\eta) = g(x_0 + \eta u)$

In the Taylor's series given by Eq. (13) yields

$$g(x_0 + \eta u) = g(x_0) + \eta \left. \frac{d}{d\eta} \right|_{\eta=0} g(x_0 + \eta u) + \frac{\eta^2}{2} \left. \frac{d^2}{d\eta^2} \right|_{\eta=0} g(x_0 + \eta u) + \dots \quad \text{Eq. (14)}$$

neglect

Neglecting the higher order terms of the Taylor's series given by Eq. (14) gives us the change or increment in the nonlinear function $g(x)$ as

$$g(x_0 + \eta u) \approx g(x_0) + \eta \left. \frac{d}{d\eta} \right|_{\eta=0} g(x_0 + \eta u) \quad \text{Eq. (15)}$$

Since η is an artificial parameter which is used to perform the derivative, we can eliminate it from Eq. (15) by substituting $\eta = 1$ in Eq. (15). This yields

$$g(x_0 + u) \approx g(x_0) + \left. \frac{d}{d\eta} \right|_{\eta=0} g(x_0 + \eta u) \quad \text{Eq. (16)}$$

Bonet, Gil, and Wood - 2016

Now, we can introduce our definition G of η was G of x_0 plus ηu ok. So, when we introduce this in equation number 13 which was there on the previous slide we can write G of x_0 plus ηu as G of x_0 plus d by $d\eta$ evaluated at η equal to 0 of G of x_0 plus ηu plus η^2 by $2d^2$ by $d\eta^2$ of G of x_0 plus ηu evaluated at η equal to 0 plus so, on ok. Now, we as we did in a single non-linear equation case we will neglect these higher order terms ok. What we will do is will neglect these higher order terms ok.

So, if you neglect the higher order terms, so, the left hand side will be approximately equal to G of x_0 plus the linear term in η ok. Now, the problem here is we have unknown η and we also have unknown u the direction in which we want to get the solution. It is the direction u is the direction which will take us closer to the solution because η was an artificial parameter which was only used to perform the derivative. So, we can simply eliminate η from our equation number 15 by just substituting η equal to 1 ok.

So, when we substitute η equal to 1, so, this η will be equal to 1 and this η will be equal to 1 ok. So, the η here ok. So, this is no η in this term because η has been substituted with 0 ok. So, there is no η here. So, what we get here is this equation 16, ok.

(Refer Slide Time: 30:38).

1. Linearization and Directional Derivative 11

The second term on the right hand side of Eq. (16) is identified to be the directional derivative of $G(x_0)$ at x_0 in the direction of u . The is given by

$$D\mathcal{G}(x_0)[u] = \left. \frac{d}{d\eta} \mathcal{G}(x_0 + \eta u) \right|_{\eta=0} \quad \text{Eq. (17)}$$

Note: u can be either a list of variables or a set of functions. Therefore, the term "in the direction of" is very general at the moment in terms of its interpretation.

Using Eq. (17) in Eq. (16) we have

$$\mathcal{G}(x_0 + u) \approx \mathcal{G}(x_0) + D\mathcal{G}(x_0)[u] \quad \text{Eq. (18)}$$

Setting $\mathcal{G}(x_0 + u) = 0$ we get

$$\mathcal{G}(x_0) + D\mathcal{G}(x_0)[u] = 0 \quad \text{Eq. (19)}$$

Note: Eq. (19) is a linear equation with respect to u .

Bonet, Gil, and Wood - 2016

Now, this second term on the right hand side of equation 16 is what is identified to be the directional derivative of x_0 of G directional derivative of G of x_0 at x_0 in the direction of u and this is written as $d G x_0$ in u $DG x_0$ evaluated in the direction u and this can be calculated using following expression on the right hand side ok.

So, you write the system of I mean you write the non-linear equations by substituting x as x_0 plus ηu then you take the derivative of that with respect to η and then finally, you substitute η equal to 0. So, this will lead to if this will give you the directional derivative of G at x_0 in the direction u , ok. So, you have to note that u can be either list of variable or a set of functions. So, therefore, when you are using this term in the direction of right now, is a very general term at the moment in terms of its interpretation ok.

So, I mean if you ask what is direction in the direction of a function, I mean it does not actually mean anything. That is why we when we say in the direction of therefore, its meaning is very general at the moment ok. Now, when you use equation number 17 in equation 16 on the right hand side in right hand side of equation 16, we substitute. We will get the new approximation of the function value G of x_0 plus u as the old value of non-linear equations at x_0 plus a linearized approximation DG evaluated at x_0 in the direction u , ok.

Now, if you set the left hand side equal to 0, then you get G of x_0 plus directional derivative of G at x_0 in the direction u equal to 0 ok. Now, this directional derivative of G at x_0 in the direction u is a linear function is linear in u ok. So, this equation 19 is a linear equation with respect to u . So, you can basically solve for u and this will help you set up the Newton-Raphson procedure ok.

(Refer Slide Time: 33:36)

1. Linearization and Directional Derivative 12

The general Newton-Raphson procedure can be set up as

$$D\mathcal{G}(x_k)[u] = -\mathcal{G}(x_k) \quad k = 0, 1, 2, 3, \dots \quad \text{Eq. (20)}$$

$$x_{k+1} = x_k + u \quad k = 0, 1, 2, 3, \dots \quad \text{Eq. (21)}$$

Bonet, Gil, and Wood - 2016

So, like previously we replace x_0 by x_k a general k th step and we write you want to solve DG , directional derivative of G at x_k in the direction u will be equal to minus of G evaluated at x_k , where k goes from 1 2 0 1 2 3 and then the new solution x_{k+1} will be the old solution x_k plus the direction u which has been computed in from equation number 20 and then you iterate ok. So, you start with x equal to 0 you start with a k equal to 0 sorry and then you have x_0 you compute u get the value of x_1 you go back check the convergence criteria.

And if the criteria is not fulfilled then you compute x_1 x_2 then you again compute u and then compute x_2 as x_1 plus u and you keep on doing this till you achieve your convergence criteria ok. So, this establishes the Newton-Raphson procedure for non-linear equations given by G of x equal to 0 ok.

(Refer Slide Time: 35:01).

13

1. Linearization and Directional Derivative

- Properties of Directional Derivative

(a) If $\mathcal{G}(x) = \mathcal{G}_1(x) + \mathcal{G}_2(x)$ then

$$D\mathcal{G}(x_0)[u] = D\mathcal{G}_1(x_0)[u] + D\mathcal{G}_2(x_0)[u]$$

(b) If $\mathcal{G}(x) = \mathcal{G}_1(x) \cdot \mathcal{G}_2(x)$ then

$$D\mathcal{G}(x_0)[u] = D\mathcal{G}_1(x_0)[u] \mathcal{G}_2(x_0) + \mathcal{G}_1(x_0) D\mathcal{G}_2(x_0)[u]$$

(c) If $\mathcal{G}(x) = \mathcal{G}_1(\mathcal{G}_2(x))$ then

$$\Rightarrow D\mathcal{G}(x_0)[u] = D\mathcal{G}_1(\mathcal{G}_2(x_0)) [D\mathcal{G}_2(x_0)[u]] \Leftarrow$$

Bonet, Gil, and Wood - 2016

So, there are some properties of directional derivative which will be needed in the worked out examples that we will do and we will revise these three properties. The first one is if the given non-linear equation can be written as addition or the sum of two sets of non-linear equations $G_1(x)$ plus $G_2(x)$ then the directional derivative of G at x_0 in the direction u will be the directional derivative of G_1 at x_0 in the direction u plus the directional derivative of G_2 at x_0 in the direction u .

The next is if you can write your given non-linear equation as a product of two functions G_1 and G_2 , so, $G_1(x)$ into $G_2(x)$, then the directional derivative of G at x_0 in the direction u will be the directional derivative of G_1 in the direction u evaluated at x_0 times G_2 evaluated at x_0 plus G_1 at x_0 times directional derivative of G_2 at x_0 evaluated in the direction u .

Now, this dot I mean this dot that you see here, again its very general has a very general meaning right now. I mean it does not actually mean the multiplication. The last property is suppose your G of x is G_1 function of G_2 which is again function of x , then the directional derivative of G at x_0 in the direction u will be nothing but the directional derivative of G_1 at G_2 evaluated at x_0 in the direction in the direction of the directional derivative of G_2 evaluated at x_0 in the direction u , ok. So, understand it is a little bit confusing right now. So, next we will see this last property in much more detail in the next slide.
