Lecture - 35

(Refer Slide Time: 00:26)

Hello and welcome, let us continue with differential geometry of surfaces. A little recap, the last time we had classified points on surfaces with respect to the tangent plane. Let us revisit that discussion. So, we have the surface patch, we had a point P, we had a tangent plane passing through that point, we had another point R on the surface patch. We had drawn vector P R and a normal to the tangent plane n at P.

We computed this distance d as the projection of P R on n. Let me quickly go through the math and highlight the salient points. So, this 2 by 2 matrix here was something we called the second fundamental matrix. It involved the second partial derivative of the parametric equations of the surface patch with respect to one of the parameter u mixed second partial derivatives of r with respective two parameters u and v and the second partial derivative of r with respective second parameter v and also this matrix involved the normal vector to the tangent plane.

(Refer Slide Time: 02:13)

Classification of points on the surface

$$d = \frac{1}{2}(Ldu^2 + 2Mdu dv + Ndv^2)$$

tangent plane intersects the surface at all points where $d = 0$

$$Ldu^2 + 2Mdu dv + Ndv^2 = 0 \Rightarrow du = \frac{-M \pm \sqrt{M^2 - LN}}{L} dv$$

Case 1: $M^2 - LN < 0$ No real value of du

P is the only common point between the tangent plane and the surface

P = ELLIPTICAL POINT

No other point of intersection

We had found the equation for d which is the projection of P R two points on a surface patch on the normal passing through the point P on the patch as half $L d u$ square plus $2 M d u d v$ plus $N d v$ square. The figure that the tangent plane intersects the surface at all points where d equals 0 and we had computed the corresponding condition for that. So, we had $L d u$ square plus $2 M d u d v$ plus $N d v$ square equals 0 and that gave us the expressions for $d u$ in terms of $d v$ and the three coefficients L , M and N corresponding to the second fundamental matrix d .

So, we have $d u$ equals minus M plus minus the square root of M square minus $L N$ over L . We consider four cases. The first case corresponded to this discriminate M square minus $L N$ smaller than 0. In that case, we had no solution. So, point P was the only point common between the tangent plane passing through it and the surface patch. We called that point the elliptic or elliptical point.

(Refer Slide Time: 04:01)

Classification of points on the surface

Case 2: $M^2 - LN = 0$ $L^2 + M^2 + N^2 > 0$ $du = -(M/L)dv$
 $u - u_0 = -(M/L)(v - v_0)$
tangent plane intersects the surface along this straight line
P = PARABOLIC POINT

Case 3: $M^2 - LN > 0$ two real roots for du
tangent plane at P intersects the surface along two lines
passing through P **P = HYPERBOLIC POINT**

Case 4: $L = M = N = 0$

The second case where the discriminant $M^2 - LN$ equals 0 where $L^2 + M^2 + N^2$ is greater than 0. We have a condition, which corresponds to the equation of line $u - u_0 = -(M/L)(v - v_0)$. That implies basically that the tangent plane intersects the surface along a straight line. We call such a point P as a parabolic point.

Third case, when the discriminant is greater than 0. In this case, we have two real roots for du to the tangent plane basically, at P intersects the surface along two lines passing through P. We name P in this case as a hyperbolic point and fourth case of course, is when the elements L, M and N of the second fundamental matrix are all 0 in which case we call P as a flat point.

(Refer Slide Time: 05:41)

Normal and geodesic curvatures

$k_n = \kappa_n n$ normal curvature
 $k_g = \kappa_g t_g$ geodesic curvature

$k = \kappa n_c = \frac{dt}{ds} = k_n + k_g$

Since $n \cdot t = 0$

$$\frac{dn}{ds} \cdot t + n \cdot \frac{dt}{ds} = 0$$

since k_n and n are perpendicular $k_n \cdot n = 0$

$$\begin{aligned} \frac{dn}{ds} \cdot n &= (k_n + k_g) \cdot n = k_n \cdot n = \kappa_n n \cdot n = \kappa_n \\ &= -t \cdot \frac{dn}{ds} = -\frac{dr}{ds} \cdot \frac{dn}{ds} = -\frac{dr \cdot dn}{dr \cdot dr} \end{aligned}$$

Today, we talk about Gaussian and mean curvature of surfaces in lecture number 35, but first let us talk about normal and geodesic curvatures. So, we have a surface patch and we have curve. Let us say playing on the patch, we will plot a point P on the curve and a tangent along this curve at point P. We also sketch a vector normal or perpendicular to this vector t and we call it n.

Now, here I would want you to follow the construction rather carefully. Let us sketch another vector and call it n sub c. So, n sub c happens to be the unit vector along this direction and the magnitude of this vector, let us say is given by kappa. So, this vector is kappa times n sub c. I will tell you what or how n c is related to these two vectors. Let us extend this normal vector n in the opposite direction and name this vector kappa sub n times n. Let us join the two heads of these two vectors and name the resulting vector as kappa sub g times t g. t sub g is also a unit vector along this direction.

The question you would want to ask yourself is how all these two vectors n sub c and t sub g related to t? n sub c is the first derivative of t with respect to the parametric out line. So, n sub c would be perpendicular to t and you will have to be a little observant here, if you realize t sub g is a vector that lies on the plane defined by this vector n and this vector n sub c. Consequently, t sub g will also be perpendicular to t. Let me repeat, the unique tangent here is perpendicular to the unit normal since n c is the first derivative

of t with respect to the parameter s which is the arc length parameter, n is perpendicular to t .

So, the plane containing n and n_c is perpendicular to t or let me put it the other way round. Tangent t is perpendicular to the plane containing n and n_c and by construction t_g happens to lie on this plane. So, t_g will be perpendicular to t . Once, you understand this geometric construction let us proceed with some algebra and normal curvatures of course. $k_{sub\ n}$ is equal to $\kappa_{sub\ n}$ times n and we call $k_{sub\ n}$ as the normal curvature. $k_{sub\ g}$ is equal to $\kappa_{sub\ g}$ times t_g and we call this $k_{sub\ g}$ as geodesic curvature. k is equal to κ times n_c which is respect to here and that is given by the first derivative of the tangent with respect to the arc length parameter as I mentioned before and by vector algebra a vector law of addition k_n , which is this vector plus k_g which is this vector here equals κ times n_c which is k .

Now, we know that n is normal and this tangent is perpendicular so n dotted with t is equal to 0, we differentiate this one time with respect to the arc length parameter s . So, we have total n over total s dotted with t plus n dotted with total t over total s equal 0. All we have done is we have differentiated this expression with respect to s . Now, since $k_{sub\ g}$ and n are perpendicular $k_{sub\ g}$ is this vector here and we have constructed this vector so that n and $\kappa_{sub\ g}$ times t_g make a 90 degree angle here.

So, we will have $k_{sub\ g}$ dotted with n as 0. Coming back to this result, $d t / d s$ dotted with n is equal to $k_{sub\ n}$ plus $k_{sub\ g}$ this vector dotted with n . Now, if you realize this vector comes from this relation here. We expand this result here. So, we have $k_{sub\ n}$ dotted with n plus $k_{sub\ g}$ dotted with n and because of the construction because this angle is 90 degrees $k_{sub\ g}$ dotted with n is 0 so we are left with $k_{sub\ n}$ dotted with n .

We substitute for $k_{sub\ n}$ as $\kappa_{sub\ n}$ times n dotted with n which is equal to $\kappa_{sub\ n}$ the scale. Now, $d t / d s$ dotted with n is equal to minus of $d n / d s$ dotted with t . You bring this on the right hand side and this is equal to minus of $d r / d s$ dotted with $d n / d s$. Simply, because the tangent t is defined as the first derivative of r with respect to s . What is r here? r is the parametric equation of this curve. Now, this is equal to minus of $d r$ dotted with $d n$ over $d r$ with dotted with $d r$. How did this happen? One has to be careful; it gives you the impression that this dot product is getting transferred to the

numerator and the denominator while this is not the case correctly. Let me explain this to you on the board. So, this how this happens.

(Refer Slide Time: 15:30)

Let us say you have this curve r as the function of the outline parameter s , I can also write this thing as r as a function of another parameter u . This curve is lying over the surface patch that we are considering. Now, minus of $d r$ over $d s$ dotted with $d n$ over $d s$. I said that this was equal to minus of $d r$ dotted with $d n$ over $d r$ dotted with $d r$. How did this happen? Let us find out. So, I can write $d s$ as modulus of r dot $d u$ and I can substitute this result here. So, I get minus of $d r$ over modulus of r dot $d u$ dotted with $d n$ over modulus of r dot $d u$. Since, these are scalars I can club them together.

(Refer Slide Time: 17:17)

I can write this thing as minus of d r over modulus of r dot square d u dotted with d n over d u. This is equal to minus of 1 over what is r dot square; this is equal to d r over d u dotted with d r over d u times d r over d u dotted with d n over d u.

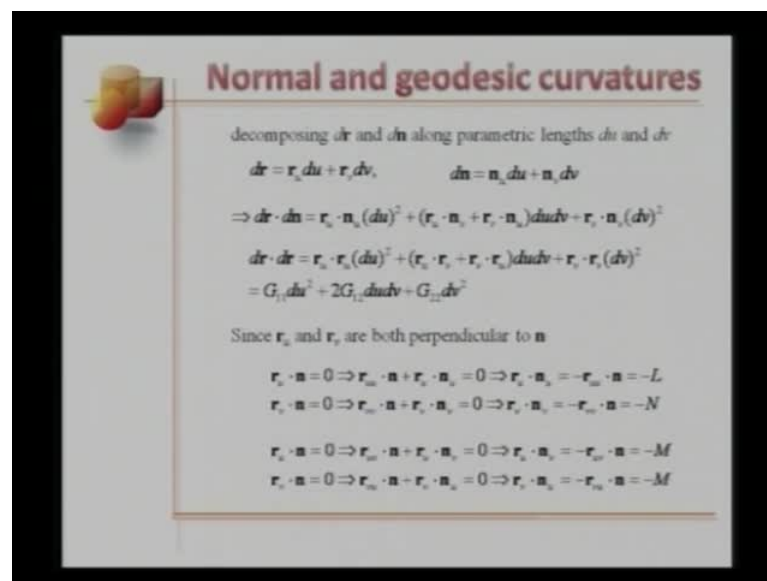

(Refer Slide Time: 18:44)

So, I will do a little hand waving here. If you notice this result is a limiting case of limit delta u tends to 0, delta r over delta u dotted with delta n over delta u over delta r, so these are vectors over delta u dotted with delta r over delta u. The numerators are vectors here while the denominators are scalars. Maybe I can take this scalars away and I can

write thing as $\frac{1}{\Delta u} \frac{\Delta \mathbf{r} \cdot \Delta \mathbf{n}}{\Delta u}$ over $\frac{1}{\Delta u} \frac{\Delta \mathbf{r} \cdot \Delta \mathbf{r}}{\Delta u}$. I can cancel these. So, I am left with limit $\Delta u \rightarrow 0$ $\frac{\Delta \mathbf{r} \cdot \Delta \mathbf{n}}{\Delta \mathbf{r} \cdot \Delta \mathbf{r}}$. And your conditions that $\Delta \mathbf{r}$'s and $\Delta \mathbf{n}$ are very small, you can change the notation and we can write this result as $\frac{d\mathbf{r} \cdot d\mathbf{n}}{d\mathbf{r} \cdot d\mathbf{r}}$. There was a negative sign here. This is how probably we get from here to here. What is next?

(Refer Slide Time: 21:01)

Now, what we can do is we can decompose $d\mathbf{r}$ and $d\mathbf{n}$ along parametric lengths du and dv . So, here we are going to be using the information from the curve and try to convert that into the information pertaining to the surface patch on which the curve lies. So, $d\mathbf{r}$ equals $\mathbf{r}_u du + \mathbf{r}_v dv$. Likewise, $d\mathbf{n}$ equals $\mathbf{n}_u du + \mathbf{n}_v dv$. We can also think of these results being obtained from the first order Taylor series expansion. Now, $d\mathbf{r} \cdot d\mathbf{n}$ in numerator in the result that we have seen before is equal to $\mathbf{r}_u \cdot \mathbf{n}_u du^2 + (\mathbf{r}_u \cdot \mathbf{n}_v + \mathbf{r}_v \cdot \mathbf{n}_u) du dv + \mathbf{r}_v \cdot \mathbf{n}_v dv^2$.

Just in case, if you have forgotten while the subscripts being here, \mathbf{r}_u is the partial derivative of \mathbf{r} with respect to u and \mathbf{r}_v is partial derivative of \mathbf{r} with respect to v and the same goes for \mathbf{n}_u and \mathbf{n}_v . We have final term of $d\mathbf{r} \cdot d\mathbf{n}$ as $\mathbf{r}_v \cdot \mathbf{n}_v dv^2$. Likewise, the denominator of the previous result $d\mathbf{r} \cdot d\mathbf{r}$

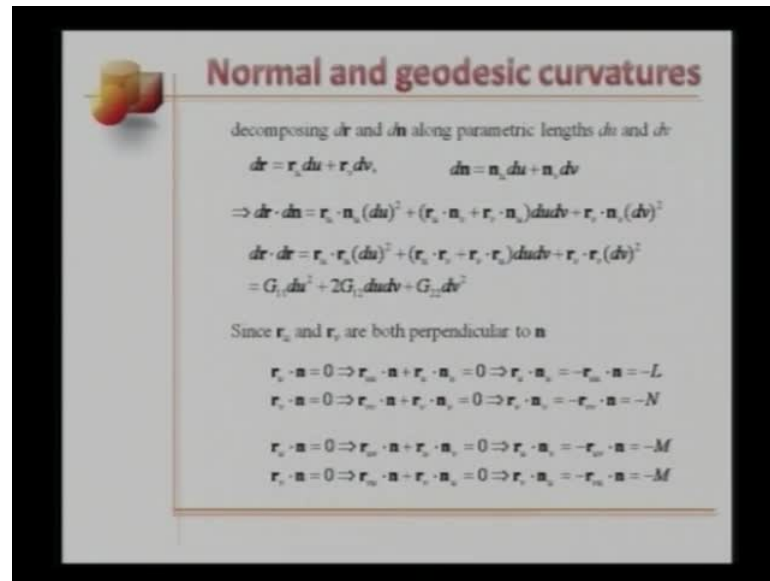

dotted with $d\mathbf{r}$ is equal to \mathbf{r}_u dotted with \mathbf{r}_u times du square plus \mathbf{r}_u dotted with \mathbf{r}_v plus \mathbf{r}_v dotted with \mathbf{r}_u times $du dv$ plus \mathbf{r}_v dotted with \mathbf{r}_v times dv square.

In terms of the elements of the first fundamental matrix G , \mathbf{r}_u dotted with \mathbf{r}_u is G_{11} times du square plus 2 times G_{12} times $du dv$, each of these is $G_{11} + G_{22}$ times dv square. This is what $d\mathbf{r}$ dotted with $d\mathbf{r}$ is. Now, we can use the fact that both the tangents \mathbf{r}_u and \mathbf{r}_v are the point on the surface are perpendicular to the normal to the surface at that point. So, we have \mathbf{r}_u dotted with \mathbf{n} is equal to 0 and if we differentiate that with respect to u again, this implies the second partial derivative of \mathbf{r} with respect to u dotted with \mathbf{n} plus \mathbf{r}_u dotted with \mathbf{n}_u equals 0.

This implies \mathbf{r}_u dotted with \mathbf{n}_u equals negative of \mathbf{r}_{uu} dotted with \mathbf{n} . Now, if you look at this expression here, this corresponds to the first element L of the second fundamental matrix. Likewise, \mathbf{r}_v dotted with \mathbf{n} equals 0 can be differentiated with respect to v to get \mathbf{r}_{vv} dotted with \mathbf{n} plus \mathbf{r}_v dotted with \mathbf{n}_v equals 0. This implies that \mathbf{r}_v dotted with \mathbf{n}_v equals minus of \mathbf{r}_{vv} dotted with \mathbf{n} and what is this? This is equal to minus n the fourth element of d , the second fundamental matrix.

Let us use this relation again and maybe differentiate this with respect to v . So, you will get the mixed derivative here \mathbf{r}_{uv} dotted with \mathbf{n} plus \mathbf{r}_u dotted with \mathbf{n}_v equals 0 and this implies that \mathbf{r}_u dotted with \mathbf{n}_v equals minus of \mathbf{r}_{uv} dotted with \mathbf{n} . And this result here is equal to minus of M and this is the second or the third element of d , the second fundamental matrix. We can likewise differentiate this expression with respect to u to finally get minus of \mathbf{r}_{vu} dotted with \mathbf{n} equals minus M . Where are we heading? Let us find out.

(Refer Slide Time: 28:08)

If you notice we were after computing the expression for the normal curvature κ_n and this would be equal to $L du^2 + 2M du dv + N dv^2$ over $G_{11} du^2 + 2G_{12} du dv + G_{22} dv^2$. This is equal to $L + 2M \mu + N \mu^2$ over $G_{11} + 2G_{12} \mu + G_{22} \mu^2$. Let us get back to the expression here. Let us go back and try to recap what we have done.

So, here we had the expression of normal curvature κ_n . It was equal to minus of $d\mathbf{r} \cdot d\mathbf{n}$ over $d\mathbf{r} \cdot d\mathbf{r}$. We expanded $d\mathbf{r}$ in terms of the tangents \mathbf{r}_u and \mathbf{r}_v , also we did the same for this normal here $d\mathbf{n}$ in terms of \mathbf{n}_u and \mathbf{n}_v . This is a quick recap. We computed $d\mathbf{r} \cdot d\mathbf{n}$ and $d\mathbf{r} \cdot d\mathbf{r}$ in terms of the elements of the first fundamental matrix G and the second fundamental matrix d . All we have done is we have substituted for the numerator and denominator for κ_n , right here.

(Refer Slide Time: 30:38)

Normal and geodesic curvatures

the expression for the normal curvature is

$$\kappa_n = \frac{Ldv^2 + 2Mdu dv + Ndu^2}{G_{11}dv^2 + 2G_{12}du dv + G_{22}du^2} = \frac{L + 2M\mu + N\mu^2}{G_{11} + 2G_{12}\mu + G_{22}\mu^2}$$

where $\mu = \frac{dv}{du}$

The above equation can be written as

$$(G_{11} + 2G_{12}\mu + G_{22}\mu^2)\kappa_n = L + 2M\mu + N\mu^2$$

For an optimum value of normal curvature $\frac{d\kappa_n}{d\mu} = 0$

Differentiation yields

$$(G_{11} + 2G_{12}\mu + G_{22}\mu^2) \frac{d\kappa_n}{d\mu} + 2(G_{12} - G_{22}\mu)\kappa_n = 2(M - N\mu)$$

$$\Rightarrow (G_{11} + G_{22}\mu)\kappa_n = (M + N\mu)$$

This is dr dotted with dn and this is dr dotted with dr . The minus sign has gotten absorbed in the algebra. What is μ here? μ is dv over du . All we have done is we have divided the numerator and denominator by du square respectively. The above equation can of course, be written as $G_{11} + 2G_{12}\mu + G_{22}\mu^2$ times κ_n , we are transferring this denominator here and that is equal to $L + 2M\mu + N\mu^2$.

What do we have here? We have a quadratic $N\mu$. That would allow us may be to compute the optimum value of the normal curvature κ_n . If κ_n is the objective here and if we are trying to find an extremum or extrema for κ_n we will have to use the first order conditions. That correspond to the total of the κ_n with respect to μ and that should be equal to 0 to get a set of stationary points.

So, if we differentiate this expression with respect to μ , we have $G_{11} + 2G_{12}\mu + G_{22}\mu^2$ times total κ_n over total μ plus 2 times $G_{12} + G_{22}\mu$ times κ_n and that is equal to 2 times $M + N\mu$. So, this here corresponds to the differentiation of the expression on the left hand side and this here corresponds to the same for the expression on the right hand side. All we need to do is we need to set $d\kappa_n / d\mu = 0$. That would give us $G_{12} + G_{22}\mu$ times $\kappa_n = M + N\mu$. This expression goes off to 0.

(Refer Slide Time: 34:19)

Normal and geodesic curvatures

Thus

$$\kappa_n = \frac{M + N\mu}{G_{11} - G_{22}\mu} = \frac{L + 2M\mu + N\mu^2}{G_{11} + 2G_{12}\mu + G_{22}\mu^2} = \frac{(L + M\mu) - \mu(M + N\mu)}{(G_{11} + G_{22}\mu) - \mu(G_{11} + G_{22}\mu)}$$

This can be simplified to

$$\kappa_n = \frac{M + N\mu}{G_{11} + G_{22}\mu} = \frac{L + M\mu}{G_{11} + G_{22}\mu}$$

$$\Rightarrow (M - G_{11}\kappa_n) + (N - G_{22}\kappa_n)\mu = 0$$

$$(L - G_{11}\kappa_n) + (M - G_{22}\kappa_n)\mu = 0$$

$$\Rightarrow \begin{bmatrix} (M - G_{11}\kappa_n) & (N - G_{22}\kappa_n) \\ (L - G_{11}\kappa_n) & (M - G_{22}\kappa_n) \end{bmatrix} \begin{bmatrix} 1 \\ \mu \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

For a non trivial solution, the determinant of the coefficient matrix is zero

Therefore, kappa sub n is equal to M plus N mu over G 1 2 plus G 2 2 times mu and this is equal to L plus 2 M times mu plus N times mu square over G 1 1 plus 2 G 1 2 mu plus G 2 2 times mu square. Where did this expression come from? If you notice this is how kappa n was determined before. This here gave the original expression for kappa n. So, I can write this expression as L plus M mu plus mu times M plus N mu over G 1 1 plus G 1 2 times mu plus mu times G 1 2 plus G 2 2 times mu. All I have done is I have separated this term here and likewise I have separated this term here and I have rewritten this addition in the numerator here and correspondingly the addition and the denominator here. We can simplify this to kappa n equals M plus N mu over G 1 2 plus G 2 2 mu, which is equal to L plus M mu over G 1 1 plus G 1 2 mu which implies that M minus G 1 2 times kappa n plus n minus G 2 2 times kappa n times mu is equal to 0.

I would advise you to work and get this expression by hand. We also have L minus G 1 1 times kappa n plus M minus G 1 2 times kappa n times mu equals 0. So, this equation here which are two equations if you think about it can be rewritten in these forms. In matrix form I can write these two equations as M minus G 1 2 times kappa n N minus G 2 2 times kappa n L minus G 1 1 times kappa n M minus G 1 2 times kappa n. These four elements form this 2 by 2 matrix times the column vector containing 1 and mu and this is equal to 0 column vector. If you want to have a non trivial solution to these two equations this matrix has to be salient, in other words the determinant of this matrix as to be 0.

(Refer Slide Time: 39:05)

Max and Min normal curvatures

$$\begin{vmatrix} (M - G_{12}\kappa_n) & (N - G_{22}\kappa_n) \\ (L - G_{11}\kappa_n) & (M - G_{12}\kappa_n) \end{vmatrix} = 0$$

or $(G_{11}G_{22} - G_{12}^2)\kappa_n^2 - (G_{11}N + G_{22}L - 2G_{12}M)\kappa_n + (LN - M^2) = 0$

$$\kappa_n^2 - \frac{G_{11}N + G_{22}L - 2G_{12}M}{G_{11}G_{22} - G_{12}^2}\kappa_n + \frac{LN - M^2}{G_{11}G_{22} - G_{12}^2} = 0$$

$\Rightarrow \kappa_n^2 - 2H\kappa_n - K = 0$ with

$$H = \frac{G_{11}N + G_{22}L - 2G_{12}M}{2(G_{11}G_{22} - G_{12}^2)} \quad \text{and} \quad K = \frac{LN - M^2}{G_{11}G_{22} - G_{12}^2}$$

$\Rightarrow \kappa_n = (H \pm \sqrt{H^2 - K})$

Thus $(\kappa_n)_{\max} = \kappa_{\max} = (H + \sqrt{H^2 - K})$
 $(\kappa_n)_{\min} = \kappa_{\min} = (H - \sqrt{H^2 - K})$

K is the Gaussian curvature... H is the mean curvature

That would give us $G_{11}G_{22} - G_{12}^2$ minus $G_{11}N + G_{22}L - 2G_{12}M$ times κ_n plus $LN - M^2$ is equal to 0. We have another quadratic in terms of κ_n . So, $\kappa_n^2 - \frac{G_{11}N + G_{22}L - 2G_{12}M}{G_{11}G_{22} - G_{12}^2}\kappa_n + \frac{LN - M^2}{G_{11}G_{22} - G_{12}^2} = 0$; this equation is the rewritten form of this one.

In short we have $\kappa_n^2 - 2H\kappa_n - K = 0$, where H has this coefficient here $\frac{G_{11}N + G_{22}L - 2G_{12}M}{2(G_{11}G_{22} - G_{12}^2)}$ and K as $\frac{LN - M^2}{G_{11}G_{22} - G_{12}^2}$, which is this constantly. So, if you notice the normal curvature κ_n is expressed in terms of the elements pertaining to the first and the second fundamental matrix. To be more specific we are also talking about the extremum points for κ_n .

Of course, we know by now how to solve a quadratic equation $\kappa_n^2 - 2H\kappa_n - K = 0$. So, we will have one extremum κ_n max or K max as $H + \sqrt{H^2 - K}$ and a minimum κ_n min equals κ_n min which is equal to $H - \sqrt{H^2 - K}$. This coefficient here H is called the mean curvature and K is called the Gaussian curvature. So, today we did quite a bit of math. Let me try to solve an example for you on board so that

we can absorb the discussions in this lecture. Let us try to determine the Gaussian and mean curvatures for a monkey saddle.

(Refer Slide Time: 43:21)

The monkey saddle is given by r a function of two parameters u and v as u times vector i plus v times vector j plus u cube minus $3 u v$ squared times vector k . I will show you later how this looks graphically, but for now let us try to compute the elements of the first and the second fundamental matrices. In ordered form I can write this thing as u comma v comma u cube minus $3 u v$ squared. So, we have r sub u which is partial r over partial u , this is equal to $1 \ 0 \ 3 u$ squared minus $3 v$ squared. We have r sub v equals partial r over partial v , this is equal to $0 \ 1$ this would be 0 will have minus $6 u v$.

You would need this second partial derivatives as well. Let us try to compute them. So, r u u equals partial $^2 r$ over partial u square will be equal to $0 \ 0$ derivative of this expression with respect to u this would give us $6 u$, partial r u v equals partial $^2 r$ over partial u partial v which is equal to I will have to differentiate this with respect to v , so I will have $0 \ 0$ and this is minus of $6 v$. The mixed second derivative r u v is partial $^2 r$ over partial u partial v , I have already computed that. The second derivative of r with respect to v r v v equals partial $^2 r$ over partial v square, this is equal to, we will have to differentiate this expression here with respect to v will have $0 \ 0$ and minus $6 u$.

(Refer Slide Time: 47:46)

$$\vec{n} = \frac{\vec{r}_u \times \vec{r}_v}{|\vec{r}_u \times \vec{r}_v|} \quad \vec{r}_u \times \vec{r}_v = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ 1 & 0 & 3u^2 - 3v^2 \\ 0 & 1 & -6uv \end{vmatrix}$$

$$-\hat{i}(3u^2 - 3v^2) + \hat{j}(6uv) + \hat{k}(1)$$

$$\vec{n} = \frac{-(3u^2 - 3v^2)\hat{i} + 6uv\hat{j} + \hat{k}}{\sqrt{(3u^2 - 3v^2)^2 + 36u^2v^2 + 1}} \quad \} D$$

$$D = \sqrt{9u^4 + 9v^4 + 18u^2v^2 + 1}$$

We would also need the expression for the normal as you would know this is equal to \mathbf{r}_u crossed with \mathbf{r}_v over the absolute value of this numerator \mathbf{r}_u cross with \mathbf{r}_v . Let us try to determine this cross product first, \mathbf{r}_u cross with \mathbf{r}_v is equal to the determinant of $\hat{i} \hat{j} \hat{k}$. \mathbf{r}_u is this expression here $1 \ 0 \ 3u^2 - 3v^2$, \mathbf{r}_v is this expression here $0 \ 1 \ -6uv$ which expand this determinant. So, we have \hat{i} times 0 minus this times this which is minus of $3u^2 - 3v^2$ plus \hat{j} times this times this minus of this times this, this minus sign goes off we have $6uv$ plus \hat{k} times this times this minus this times this, we have 1 .

So, the unit normal \mathbf{n} is equal to minus $3u^2 - 3v^2$ times \hat{i} plus $6uv$ times \hat{j} plus \hat{k} over square root of $3u^2 - 3v^2$, the whole squared plus $36u^2v^2 + 1$. Let me write this denominator as D and I can simplify D as under root of $9u^4 + 9v^4 - 18u^2v^2 + 36u^2v^2 + 1$, we will have $36u^2v^2$ from here. So, this becomes plus $18u^2v^2 + 1$. We will be needing this side of the board. So, what I will do is I will transfer this result right over here.

(Refer Slide Time: 51:43)

So, n cap equals 1 over D where you know what D is, times minus 3 u square minus 3 v squared comma 6 u v comma 1 in the order form. Let us start computing the elements of the first and the second fundamental matrices.

(Refer Slide Time: 52:17)

G 1 1 equals r u dotted with r u and that is given by 1 plus this squared 3 u squared minus 3 v squared the whole square. G 1 2 is given by r u dotted with r v which is this dotted with this. So, this multiplied by this is 0, this multiplied by this is 0. We are left

with minus $6uv$ times $3u^2 - 3v^2$ and $G_{22} = r \cdot v$ dotted with $r \cdot v$ and that is equal to $1 + 36u^2v^2$.

You know what the first fundamental matrix is given by $G_{11} G_{12} G_{12} G_{22}$ which is the same $G_{21} G_{22}$, how about the second fundamental matrix? The elements are given by $L = r_u \cdot n$, $r_u \cdot n$ is here, n is here, so what do we have? This dotted with 0 plus this dotted with 0 plus $6u$. So, we have $6u$ over D here. Let us not confuse this simple D with the second fundamental matrix itself. Let me change that symbol.

(Refer Slide Time: 54:56)

(Refer Slide Time: 55:10)

Let me call D as D sub 1 just to signify that D 1 is nothing but the absolute value of this vector. So, we have D 1 here. The second element M is given as r u v dotted with n, this is equal to minus of 6 v over D 1, this dotted with 0 plus this dotted with 0 plus this dotted with minus 6 v; and the third element N is r v v dotted with n, which is equal to minus 6 u over D 1.

(Refer Slide Time: 56:07)

The image shows a chalkboard with the following derivations:

$$\text{Gaussian curvature } K = \frac{LN - M^2}{G_{11}G_{22} - G_{12}^2}$$

$$= \frac{\left(\frac{6u}{D_1}\right)\left(-\frac{6v}{D_1}\right) - \left(-\frac{6v}{D_1}\right)^2}{1 + (3u^2 - 3v^2)^2}$$

$$\text{Mean Curvature } H = \frac{G_{11}N + G_{22}L - 2G_{12}M}{2(G_{11}G_{22} - G_{12}^2)}$$

$$= \frac{1 + 36u^2v^2 - 36u^2v^2}{2(1 + 36u^2v^2 - 36u^2v^2)}$$

There are additional annotations on the board: $\{1 + (3u^2 - 3v^2)^2\}^2$ and $(3u^2 - 3v^2)^2$.

The Gaussian curvature K is given by L N minus M squared over G 1 1 G 2 2 minus G 1 2 squared. This is equal to 6 u over D 1 times minus 6 u over D 1 minus minus 6 v over D 1 squared over G 1 1 is 1 plus 3 u squared minus 3 v squared squared G 2 2 is 1 plus 36 u squared v squared minus G 1 2 squared, which is 36 u squared v squared times 3 u squared minus 3 v squared, the whole square.

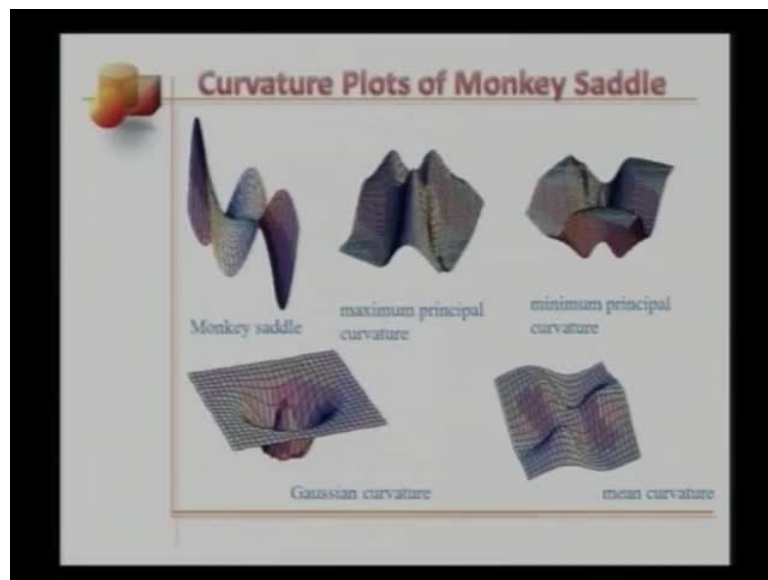

The mean curvature H is given by H equals G 1 1 N plus G 2 2 L minus 2 G 1 2 M over 2 G 1 1 G 2 2 minus G 1 2 the squared term appears here. We have the expression for G 1 1 G 2 2 and G 1 2 from here. You also know what N L and M are from here. All you would need to do is substitute for these variables or elements to get a mean curvature. Once, you have the Gaussain and mean curvatures you can compute the minimum and maximum values of kappa n, the normal curvatures.

(Refer Slide Time: 59:29)

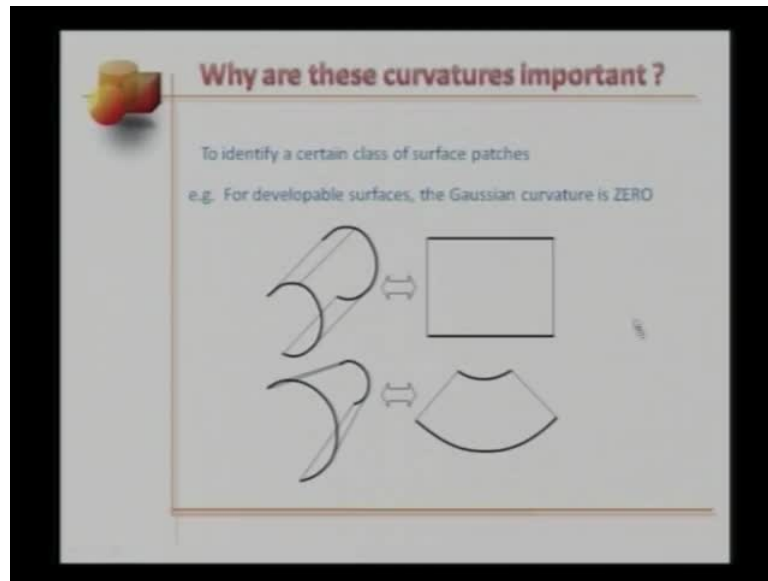

Kappa n max min as you know is given by H plus minus under root of H squared minus K.

(Refer Slide Time: 59:52)

For the example that we have just worked out this figure here shows the monkey saddle. This shows the maximum principle curvature kappa sub n, shows the minimum principle of curvature kappa sub n, this is the plot for the Gaussain curvature and this is the plot for the mean curvature.

(Refer Slide Time: 01:00:18)

Why are these curvatures important after all? With the help of these curvatures, we can identify certain classes of surface patches for example, for developable surfaces the Gaussian curvature is 0 as you would know cylindrical and conical surfaces are developable surfaces for which the Gaussian curvature is 0.
