Lecture – 04
Integration of Complex Functions

Good morning, in the previous lecture, we discussed the differential calculus part of complex analysis.

(Refer Slide Time: 00:29)

Today in this lecture we go into the integral calculus part of it and we study integrals in the complex plane. Our 2 main topics of discussion will be Cauchy's integral theorem and Cauchy's integral formula before going into those 2 topics we spend a little time to build the ground for it first we discuss the concept of line integral in the complex plane.

(Refer Slide Time: 00:51)

Line Integral

For $w = f(z) = u(x, y) + iv(x, y)$, over a smooth curve C ,

$$\int_C f(z) dz = \int_C (u+iv)(dx+idy) = \int_C (udx-vdy) + i \int_C (vdx+udy).$$

Extension to piecewise smooth curves is obvious.

With parametrization, for $z = z(t)$, $a \leq t \leq b$, with $\dot{z}(t) \neq 0$,

$$\int_C f(z) dz = \int_a^b f[z(t)] \dot{z}(t) dt.$$

Over a simple closed curve, *contour integral*: $\oint_C f(z) dz$

Example: $\oint_C z^n dz$ for integer n , around circle $z = \rho e^{i\theta}$

$$\oint_C z^n dz = i\rho^{n+1} \int_0^{2\pi} e^{i(n+1)\theta} d\theta = \begin{cases} 0 & \text{for } n \neq -1. \\ 2\pi i & \text{for } n = -1. \end{cases}$$

The M-L inequality: If C is a curve of finite length L and $|f(z)| < M$ on C , then

$$\left| \int_C f(z) dz \right| \leq \int_C |f(z)| |dz| < M \int_C |dz| = ML.$$

Now if fz is a function of z that is w is equal to fx which is expressed in this manner u and v are the real and imaginary components respectively, then we can define its line integrals over a smooth curve C in this manner that is we consider fz as u plus iv and dz is as usual dx plus idy and then the product of this, these 2 will give us the real part as udx and minus vdy which is here and the imaginary part will be vdx plus udy which is here now this real integral plus i into this real integral will give us the line integral of fz . So, this will be a complex function; obviously, because this is the real part and this is the imaginary part.

Now, this we have defined for the time being over a smooth curve C , now extension of this same definition over piecewise smooth curve is obvious because if the smoothness is interrupted at say a finite number of points, then considering those finite number of points as the endpoint of one segment of the curve at starting point of the next segment of the curve, we can build the same line integral over several segments. So, now, if particularly if we have a parameterization of the curve z in the form of z of t with respect to a real parameter t which varies from a to b that is as this parameter t varies from real number a to real number b over a an ordinary interval, then if the corresponding z of t traces that curve with this derivative never vanishing, then this line integral can be reduced to a simple definite integral because in that case we can put fz as F of z of t which means this turns out to be in terms of t and then dz can be put in terms of z dot into dt and in that case this entire thing F and z dot the product of F and z dot becomes

the integral and the integral is with respect to this real parameter t and then it is a definite integral.

So, with the parameterization of the curve C available the line integral can be reduced to a definite integral in real variable quite easily now if the closed curve is simple if the smooth curve C is taken as a closed curve simple closed curve without self intersections, then you can talk of contour integrals which is integral over a closed curve and then the symbol is used like this, let us take an example which will serve 2 purposes one to demonstrate the evaluation of integrals using this kind of formulae and second to have a little result in hand which we will be using later for a very important step in later derivations, we try to find out this particular integral for integer n know that is z to the power n simple function z to the power n we find try to find the integral of this around a circle which is centred at 0 at origin and with radius ρ , then here you see that the variable θ is the parameter the it takes the place of t in this formulation in that case this for evaluating this contour integral over the circular contour we consider z as this and then this z will be $\rho e^{i\theta}$ into this whole thing right because the derivative of this will be $i\rho e^{i\theta}$ into i .

So, from this step to this step n powers of ρ come from this and the last another additional power comes from here from the dz . So, ρ to the power $n + 1$ and since ρ is constant it is a circular contour. So, that we can take outside the integral sign and then similarly e to the power $i\theta$ n powers of that come from here and one power comes from here. So, e to the power $i\theta$ also is raised to $n + 1$ power and in the derivative of this factor i comes which is here. So, this entire thing has been now reduced to this and now since here the variable of integration is θ .

So, the integral is evaluated over θ with the limits 0 to 2π one circle will have 0 to 2π interval of the parameter angle θ now you see that the contour integral has been reduced to a ordinary definite integral in this manner right now if we try to evaluate this integral, we notice that if n is equal to minus 1, then this entire power vanishes and this integral integrand becomes one and in that case it is a simple integral of a constant function one and that will give us 2π and therefore, for n is equal to minus 1 you get 2π from here and you get $2\pi i$ as the integral.

On the other hand, if you have n as anything other than minus 1 say 0, 1, 2, 3 and so on, then this turns out to be an integer which is going to give us e to the power $i\phi$ where ϕ is $n + 1$ theta. Now we know that e to the power $i\phi$ is $\cos \phi + i \sin \phi$ and as we try to integrate that we will find that both $\cos \phi$ and $\sin \phi$ integrated over 0 to 2π will produce 0. So, real part as well as the imaginary part will give us 0 and therefore, for n not equal to minus 1, we get this integral as 0. So, this small result we will keep in hand which will be useful later; now another small result which will be quite useful in later discussion is conveniently named as the ml inequality.

Now here what do we say is that if c is a curve of finite length l and fz is a function which is bounded and the bound is m bounded means its absolute value is bounded. So, now, here is the value of fz of absolute value of greater than m . So, if the value of fz its absolute value is bounded by m over that curve, then we say that the actual value of this integral will be always less than equal to what we would get if we replace this fz and dz by their absolute values, right. So, then this is one less than equal to that is this is one inequality and then rather than fz absolute value if we put its supremum m , then this side will be further increased.

So, therefore, this will be less than equal to actually less then because of this strict inequality this thing will be less than the integral that we would get if in place of this absolute value of fz if we put the supremum value m and that value being constant can be taken out of the integral and then the absolute value of dz integrated over c actually gives us the length of the curve and that is ml . So, what we get as a result the result is that if the value of the function absolute value of the function is bounded by this m and the curve of finite length l , then this absolute value of the line integral is bounded by the product of ml and l . So, this is a convenient result which will be of use later also.

Integrals in the Complex Plane 1.84

Cauchy's Integral Theorem

Line Integral
Cauchy's Integral Theorem
Cauchy's Integral Formula

- ▶ C is a simple closed curve in a simply connected domain D .
- ▶ Function $f(z) = u + iv$ is analytic in D .

Contour integral $\oint_C f(z) dz = ?$
If $f'(z)$ is continuous, then by Green's theorem in the plane,

$$\oint_C f(z) dz = \iint_R \left(-\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) dx dy + i \iint_R \left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right) dx dy,$$

where R is the region enclosed by C .
From C-R conditions, $\oint_C f(z) dz = 0$.

Proof by Goursat: without the hypothesis of continuity of $f'(z)$

Cauchy-Goursat theorem
If $f(z)$ is analytic in a simply connected domain D , then $\oint_C f(z) dz = 0$ for every simple closed curve C in D .

Importance of Goursat's contribution:
▶ continuity of $f'(z)$ appears as consequence!

Now, we come to one of the important topics of our discussion and that is Cauchy's integral theorem that C is a simple closed curve closed curve and non intersecting in a simple connected domain D , we have already discussed what is a simple connected domain in the context of vector calculus here in the complex plane, it is the similar domain in which there is no interior boundaries no interiors whole a single boundary which is also non self intersecting that is simply closed curve simple closed curve, then if we take this function which we consider as analytic in this domain now what do we have we have a simply connected domain D in that we have an analytic function which is every analytical everywhere in this domain and we have a simple closed curve C in that domain and then we want to evaluate what is the contour integral of that function over that particular closed curve.

So, if the derivative now one point is already clear that since the function is analytic. So, it will possess derivatives. So, if that derivative is continuous then we can apply greens theorem to develop this integral this is the integral, right. So, here we talk of this integral and we remember; what is greens theorem in the plane.

(Refer Slide Time: 11:47)

And that is the line integral of a function with components F_1 F_2 which is given like this $F_1 dx$ plus $F_2 dy$ over a simple closed curve C is given by the double integral over the region enclosed by C of $\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}$ by $dx dy$ right simply stated line integral of function F over the closed curve C turns out to be equal to the surface integral of its curve over the surface bounded by C now that is the Stokes's theorem and the special case is greens theorem in the plane. Now in this particular case with this stuff $u dx$ minus $v dy$ and $v dx$ plus $u dy$ when we try to apply this greens theorem in the plane on this say on this we try to apply first $u dx$ minus $v dy$. So, for that u takes the place of this F_1 and minus v takes the place of this F_2 , right.

So, F_1 is u and F_2 is minus v right for this line integral right; so, then if we insert that. So, here we will get $u dx$ minus $v dy$ the real part and then here we will have the right side we will have as $\frac{\partial F_2}{\partial x}$. So, minus $\frac{\partial v}{\partial x}$ by $\frac{\partial F_1}{\partial y}$ minus $\frac{\partial u}{\partial y}$. So, F_1 is u . So, we will have minus $\frac{\partial u}{\partial y}$ this will be the first term and then the second term the imaginary term for that v will take the place of F_1 ; F_1 and u will take the place of F_2 . So, we will have here v is taking the place of a F_1 right. So, and v is and u is taking the place of F_2 . So, u here $\frac{\partial u}{\partial x}$ minus $\frac{\partial v}{\partial y}$ this will be the imaginary part right and then you will find that since the function F is analytics; that means, u and v its real and imaginary components will satisfy the Cauchy Riemann conditions which means $\frac{\partial u}{\partial x}$ is equal to $\frac{\partial v}{\partial y}$ and $\frac{\partial u}{\partial y}$ will be

equal to minus del v by del x; that means, both of these integrands will vanish and therefore, the entire integral will vanish

So, by applying greens theorem in the plane in this case we get this as we have developed here and then Cauchy Riemann conditions will imply that both of these integrands will vanish and will get the integral as 0. Now one important premise that we have used is that the derivative is continuous now this makes the proof simple; however, there is a more rigorous proof by Goursat which does not use the hypothesis of continuity of F from z that gives a little formal advantage to the proof by Goursat in the sense that in that case if the continuity of the derivative is not used even without using it if it is proved then the continuity of F prime appears as a consequence.

So, therefore, many authors many authors consider name this Cauchy's theorem as Cauchy's Goursat theorem and what it means it means that if f(z) is analytic in a simply connected domain D then a contour integral over a simple closed curve is 0 for every simple closed curve in C in D; that means, that if in the domain the function is analytic everywhere then whatever the closed curve simply closed simply a simple closed curve we can frame in that. So, around every contour that analytic that integral contour integral will vanish; that means, there is no information content of the function in a domain in which it is analytic everywhere this integral will always vanish over every contour.

Mathematical Methods in Engineering and Science

Integrals in the Complex Plane

Cauchy's Integral Theorem

Principle of path independence
 Two points z_1 and z_2 on the close curve C
 ► two open paths C_1 and C_2 from z_1 to z_2
 Cauchy's theorem on C , comprising of C_1 in the forward direction and C_2 in the reverse direction:

$$\int_{C_1} f(z)dz - \int_{C_2} f(z)dz = 0 \Rightarrow \int_{z_1}^{z_2} f(z)dz = \int_{C_1} f(z)dz = \int_{C_2} f(z)dz$$

For an analytic function $f(z)$ in a simply connected domain D , $\int_{z_1}^{z_2} f(z)dz$ is independent of the path and depends only on the end-points, as long as the path is completely contained in D .

Consequence: Definition of the function

$$F(z) = \int_{z_0}^z f(\xi)d\xi$$

What does the formulation suggest?

Now, as you continue in that path. So, we find that on a simple closed curve we if we take 2 points say this is simple closed curve. So, we take this as one point and this as another point now around this contour if the contour integral turns out to be 0. So, then this is one line integral from z_1 to z_2 through this path and z_1 to z_2 through this part is another contour integral. So, if we take a contour another line integral. So, now, this contour integral from z_1 to z_2 and back to z_1 is actually the sum of 2 line integrals z_1 to z_2 along this curve and z_2 to z_1 along this curve which is the second one is equivalent to the negative of the line integral from z_1 to z_2 along this curve. So, this minus this; this line integral minus this line integral will mean this line integral plus this line integral which is a contour integral which should vanish which is 0.

So; that means, if you take 2 points z_1 and z_2 on the closed curve C then these 2 points will open the contour open the closed curve into 2 open curves open paths C_1 and C_2 ; C_1 as this and C_2 as this both from z_1 to z_2 and then as we apply Cauchy's theorem on C with the 2 parts C_1 in the forward direction and C_2 in the reverse direction then we will find that the contour integral turns out to be integral over line integral over C_1 minus line integral over C_2 which should vanish by Cauchy's theorem, then that will mean that this line integral and this line integral are equal and then we can say that this line integral depends only on the endpoints and not on the curve along which we are going because as long as we keep these 2 endpoints in hand for any other curve, we can argue in the same manner.

So, this is the important result that we get that is for an analytic function in a simply connected domain this line integral from one point to another is independent of the path and depends only on the endpoints as long as the path is completely contained in D because outside D there is no guarantee of analytical analyticity in D we have taken the premise of analyticity. So, analyticity is the fundamental requirement here now as a consequence we can talk of this that is keeping one fixed point z_0 as say z_1 in place of z_1 we keep one point fixed z_0 and the other point if we keep a variable point z , then we can define a new function of z and call it a capital F . Now what does this formulation suggest this formulation is looking similar to the definition of a definition of an indefinite integral because we are keeping this z as the complex variable itself and as a result we not getting a value of the integral, but we are getting a function of z right now this will suggest.

(Refer Slide Time: 21:34)

Mathematical Methods in Engineering and Science Integrals in the Complex Plane 13.11

Cauchy's Integral Theorem

Line Integral
Cauchy's Integral Theorem
Cauchy's Integral Formula

Indefinite integral
Question: Is $F(z)$ analytic? Is $F'(z) = f(z)$?

$$\begin{aligned} \frac{F(z + \delta z) - F(z)}{\delta z} - f(z) &= \frac{1}{\delta z} \left[\int_{z_0}^{z + \delta z} f(\xi) d\xi - \int_{z_0}^z f(\xi) d\xi \right] - f(z) \\ &= \frac{1}{\delta z} \int_z^{z + \delta z} [f(\xi) - f(z)] d\xi \end{aligned}$$

f is continuous $\Rightarrow \forall \epsilon, \exists \delta$ such that $|\xi - z| < \delta \Rightarrow |f(\xi) - f(z)| < \epsilon$
 Choosing $\delta z < \delta$,

$$\left| \frac{F(z + \delta z) - F(z)}{\delta z} - f(z) \right| < \frac{\epsilon}{\delta z} \int_z^{z + \delta z} d\xi = \epsilon.$$

If $f(z)$ is analytic in a simply connected domain D , then there exists an analytic function $F(z)$ in D such that

$$F'(z) = f(z) \quad \text{and} \quad \int_{z_1}^{z_2} f(z) dz = F(z_2) - F(z_1).$$

The idea of indefinite integral, but then the implication of a definite integral the direct meaning of a definite integral is the sum of infinite number of small infinitesimal contributions that we have already considered; however, that idea of indefinite integral is that of a function capital F whose derivative turns out to be this integrand then before formally accepting this function defined in this manner as the indefinite integral of small F we should ask if we define a function like this and call it capital F, then is capital F differentiable then because if capital F is differentiable and if its derivative happens to be this integrand, then we will be able to accept this formulation as the indefinite integral of small F because the idea of indefinite integral is comes through anti differentiation that is the reverse process of differentiation. So, we ask this question is fz differentiable or if fz analytic and is the derivative equal to small F to get an answer of that we consider this from z we make a little variation delta z and then F of z plus delta z minus fz by delta z we try to evaluate the difference of this quantity with the value of small f.

Now, if Fz is actually differentiable and if its derivative happens to be F, then the limit of this as delta z tends to 0 should be same as f; small f and in that case this difference should tend to 0 as delta z tends to 0. So, we try to first evaluate this difference that is simplify it and then see whether it has a limit and what is that limit that limit should be 0 for our purposes. Now for this one by delta z is common. So, we keep it common capital F at this changed point and the original point unevaluated based on this formula. So, in

the one in one place in place of z we use z as it is in other place we use $z + \Delta z$. So, capital F of $z + \Delta z$ is this integral evaluated from z_0 to this point and capital F of z is here that is the argument of the function appears only in the limit of the upper limit of the definite integral and everything else is same now here since F is analytic. So, the integral from z_0 to this minus z_0 to this will turn out to be the integral of F from z to $z + \Delta z$ from the difference of the 2.

And if we say that this fz for the purposes of this integral business is constant because it is outside the integral sign, but we can always say that this is fz into $d\psi$ integrated from this to this now that is basically verified from the evaluation of this second integral. So, consider this integral of fz this part integral of fz from here to here fz is independent of ψ . So, fz into ψ and the difference of ψ will come out to be Δz . So, integral of this will turn out to be fz into Δz and Δz cancelled it if fz only so; that means, this fz can be inserted into integral sing in this manner now as we get this then you say that this difference is equal to this and then if the function is continuous which it must be because the function is analytic. So, analytic function must be continuous. So, since F is continuous then for whatever small epsilon neighbourhood you demand between the function values that small epsilon neighbourhood you can achieve by taking a suitable small delta neighbourhood or the variable itself that is the direct meaning of continuity.

So by taking a suitable delta neighbourhood you can achieve an epsilon neighbourhood of the function value whatever small epsilon is demanded and in that case we choose delta z to be smaller than this delta which will ensure that this is always less than epsilon right. So, in that case the epsilon constant is taken out. So, you get epsilon by delta z and in the integrand nothing remains just one so; that means, that the integral will then be simply delta z and that delta z will cancel this delta z and will give you epsilon so; that means, this whole thing is less than epsilon and what we have discussed already for whatever small epsilon neighbourhood is demanded; that means, epsilon can be indefinitely reduced in size and; that means, this will tend to 0 as delta z tends to 0 and; that means, that indeed capital F is analytic and the limit of this as delta z tends to 0 turns out to be equal to fz because the difference tends to 0.

So, therefore, we say that if fz is analytic then there exists another analytic function capital F whose derivative happens to be f ; that means, if the function f ; small f is analytic then we knew earlier that its derivative exists now we come to know that its

integral also exists which is capital F whose derivative happens to be this and the earlier definite integral that we were talking about earlier definite integral which we define based on path independence that turns out to be available from this formulation.

Mathematical Methods in Engineering and Science

Integrals in the Complex Plane

Cauchy's Integral Theorem

Line Integral
Cauchy's Integral Theorem
Cauchy's Integral Formula

Principle of deformation of paths

$f(z)$ analytic everywhere other than isolated points s_1, s_2, s_3

$$\int_{C_1} f(z) dz = \int_{C_2} f(z) dz = \int_{C_3} f(z) dz$$

Not so for path C^* .

Figure: Path deformation

The line integral remains unaltered through a continuous deformation of the path of integration with fixed end-points, as long as the sweep of the deformation includes no point where the integrand is non-analytic.

Now, this gives us the same path independence gives us another important tool and that is for principle of deformation of paths say we take an analytic function fz which is analytic everywhere other than for isolated points like this point s_1 , this point s_2 , this point s_3 at which the function is not analytic everywhere else the function is analytic I perform those few finite number of isolated points then what we can do if we construct a domain as shown by this dashed line which does not enclose these isolated points where the function is not analytic then we can say that any path connecting 2 points z_1 and z_2 in that can be continuously deformed to any other path without crossing as long as the path remains within the domain $D; \bar{D}$, then the path say C_1 can be continuously deformed to C_2 or C_3 without sweeping over any of these non analytic points right.

And in that case the integral of the function from z_1 to z_2 along all these path will turn out to be same as long as you do not sweep over these non analytic points if you sweep over the analytic points then this guarantee will not be there that is the path the line integral along C_1 along C_2 along C_3 will be all same because they fall within the domain that does not enclose the non analytic points on the other hand the same will not be true for a path which is c^* because from C_1 C_2 if you want to change to c^*

through continuous deformation then the deformation will sweep through this point. So, this we can say.

So; that means, the line integral remains unaltered through a continuous deformation of the path of integration with fixed end points because we have already seen the path independence of definite integrals as long as the function remains analytic and as you sweep across sweep through s_1 as the curve sweeps through s_1 or s_2 or s_3 that analyticity is not guaranteed. So, you cannot claim the equality of the line integral over C . So, the line integral will remain unaltered through a continuous deformation of the path of integration with fixed end points as long as the sweep of this deformation does not enclose any of the non analytic points now we try to extend the theorem which is integral theorem to multiply connected domain.

(Refer Slide Time: 31:00)

Mathematical Methods in Engineering and Science Integrals in the Complex Plane 11.11

Line Integrals
Cauchy's Integral Theorem
Cauchy's Integral Formula

Cauchy's Integral Theorem

Cauchy's theorem in multiply connected domain

Figure: Contour for multiply connected domain

$$\oint_C f(z) dz - \oint_{C_1} f(z) dz - \oint_{C_2} f(z) dz - \oint_{C_3} f(z) dz = 0.$$

If $f(z)$ is analytic in a region bounded by the contour C as the outer boundary and non-overlapping contours $C_1, C_2, C_3, \dots, C_n$ as inner boundaries, then

$$\oint_C f(z) dz = \sum_{i=1}^n \oint_{C_i} f(z) dz.$$

Now here consider this multiply connected domain the outer boundary is this and there are inner boundaries; that means, the domain consists of this region and not the interior of this not the interior of this and not the interior of this.

Now, to evaluate the integral over this we say that it is granted that the function $F(z)$ is analytic over this domain, but about the interior of these internal boundaries nothing has been seen; that means, the function could have a singularity could be non analytic somewhere inside these interior boundaries. So, what we do is that we consider a little changed contour that is we take the contour as this curve series we start from here we

will come back to here at the end start from here from this arrow we go like this and here we may a cut and come along this arrow

And then a clockwise turn along C_1 clockwise means actually negative and then along this same cut line you go back here and then come here many another cut come here another clockwise turn go back and then come here along the cut come along the arrow another third clockwise turn and then here and come back. So, this is a closed contour and this does not enclose any of the singularities this encloses the domain correctly as long as we keep these forward movement and backward movement along these cut lines very very close as close as we want.

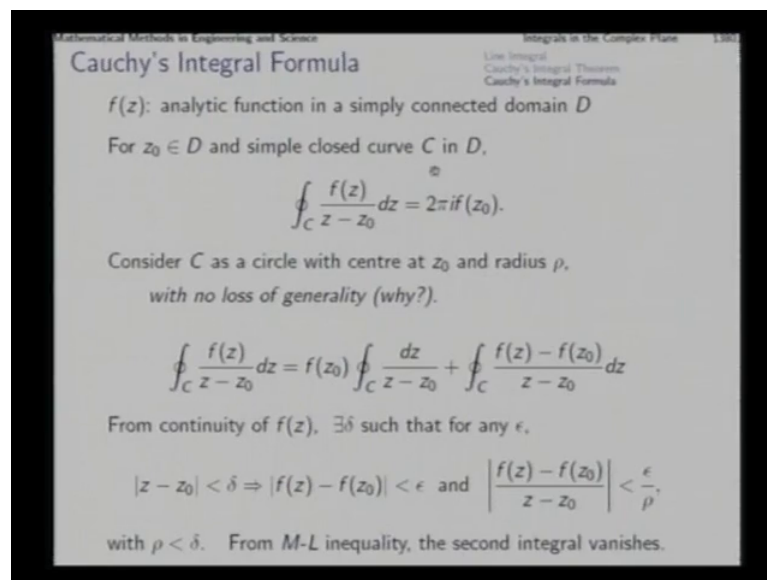

Now, the domain which this contour has enclosed is a domain in which the function is analytic everywhere and therefore, we say that over this contour the line integral vanishes the contour integral vanishes and this contour has enclosed has traversed through curve from here to here and then here to here, here to here which is the curve C that is this and then it is enclosed this line segment l_1 one forward and backward cancel this line segment l_2 forward and backward cancelled this line segment l_3 forward and backward cancelled and the 3 interior curves C_1, C_2, C_3 in the negative manner clockwise.

So, that is that is why minus the contour integrals over C_1, C_2 and C_3 this whole thing is 0 because fz is analytic everywhere in the contour that has been actually traversed now this gives us the result that if fz is analytic in a region bounded by the contour c as the outer boundary and non overlapping contour C_1, C_2, C_3 etcetera as inner boundaries in this manner, then over that outer boundary turns out to be equal to the sum of this plus this plus this that is this; that means, whatever are the inner boundaries around those inner boundaries if we develop the contour integrals then the sum of these contour integrals is going to be the contour integral over the outer boundary; that means, that whatever contribution to the contour integral over this curve C is to be made that must be made by the contours enclosing the non analytic regions inside the interior boundary only.

Those places where the function is analytic will make no contribution to this contour integral so; that means, that if we find that in the domain there are a few spots of non analyticity then around that non analyticity non analyticity non analytic small integer

parts if we evaluate the small contour integrals and then sum of these then that will account for the entire contour integral over the outer boundary and in the region in which the function is analytic from that region no fresh contribution will be made next we proceed to develop the Cauchy's integral formula.

(Refer Slide Time: 35:50)

Suppose fz is a function which is analytic in a simple connected domain D and then at a point z_0 in D and a simple close curve C enclosing that point that z_0 , we want to evaluate this integral a contour integral of fz by z minus z_0 and Cauchy's integral formula tells us that this happens to be the expression for this integral that is integral around the curve C closed curve C is given by $2\pi i$ times the function value at the integer point.

Now we see that this function fz is analytic, but fz by z minus z_0 is certainly not analytic at z_0 because at z_0 it is singular. So, which closed curve we consider as C we can consider any closed curve as long as it can be obtained through continuous deformation or any other curve right. So, without loss of generality we consider C as a circle with centre z_0 and radius ρ because any other curve could any other such simple closed curve enclosing z_0 could be reduced to this circle through continuous deformation over the analytic domain right. So, if we consider this particular curve then this integral we can evaluate as splitting it first in 2 parts that is we consider this fz as F of z_0 plus fz minus F of F_0 that F of z_0 first part we take here and that is that being independent of z comes out and we get this and the rest of it is here now the this integral we have already

evaluated earlier whenever when we are considering the integral of z to the power n . So, now, through a coordinate shift this will give you the same thing and this is the; for the power n equal to minus 1 in which case this was giving us $2\pi i$.

So, this part we know and from continuity of fz we can find out a suitable δ in order to make this less than ϵ for any small ϵ and then $z - z_0$ we can take less than δ that is a small δ neighbourhood which we give this as within an ϵ neighbourhood and then if we take the radius of the circle that ρ radius of the circle as even smaller than the corresponding δ then that will ensure that this whole thing this is less than ϵ and whatever δ is necessary for this if we take even smaller ρ as the $z - z_0$ as the radius of the circle then this thing will be less than ϵ by ρ the lower the denominator is taken as even smaller. So, this side becomes larger. So, with ρ less than δ .

So, then this fellow will be less than ϵ by ρ and then as we consider the upper bound of this then this will give us less than ϵ by ρ into the size of the in into the length of the path and the length of the path is 2π into radius $2\pi\rho$. So, the integrand is bounded ϵ by ρ and then the path length is equal to $2\pi\rho$. So, this integral will be limited the integral absolute value will be limited by the product of these 2 from ML inequality; that means, ϵ by ρ into $2\pi\rho$; that means, $2\pi\epsilon$. So, this fellow will be bounded by $2\pi\epsilon$ and that will happen for any ϵ whatever small.

That means ϵ can be demanded smaller and smaller and smaller and accordingly we will get δ and therefore, ρ which is even smaller smaller smaller. So, as we make it small enough we will be able to make this in the limit vanish and then integral will be evaluated at this and the integral of this we already know. So, the integral of this will give us $2\pi i$. So, $2\pi i F$ of z_0 that is the result. So, this establishes the Cauchy's integral formula and what are the applications of this formula there are 2 significant applications?

Cauchy's Integral Formula

Line Integral
Cauchy's Integral Theorem
Cauchy's Integral Formula

Direct applications

- ▶ **Evaluation of contour integral:**
 - ▶ If $g(z)$ is analytic on the contour and in the enclosed region, the Cauchy's theorem implies $\oint_C g(z) dz = 0$.
 - ▶ If the contour encloses a singularity at z_0 , then Cauchy's formula supplies a non-zero contribution to the integral, if $f(z) = g(z)(z - z_0)$ is analytic.
- ▶ **Evaluation of function at a point:** If finding the integral on the left-hand-side is relatively simple, then we use it to evaluate $f(z_0)$.

Significant in the solution of boundary value problems!

Example: Poisson's integral formula

$$u(r, \theta) = \frac{1}{2\pi} \int_0^{2\pi} \frac{(R^2 - r^2)u(R, \phi)}{R^2 - 2Rr \cos(\theta - \phi) + r^2} d\phi$$

for the Dirichlet problem over a circular disc.

One is evaluation of contour integral as it is proposed that is if we want to evaluate a contour integral like this then by evaluating the function at the integer point at z_0 around which the contour integral is there. So, at that point z_0 if we evaluate the function F then we get the integral of this function which happens to be singular note that F is analytic, but fz by z minus z_0 is the integrand which is not analytic. So, when we want to find out the contour integral of this around a contour inside which there is a point of singularity then singularity of this integrand fz by z minus z_0 fz is still analytic.

So, at that point if we evaluate fz that is F of z_0 multiply that with $2\pi i$ then we get the integral of this singular function singular at z_0 analytic everywhere else because one by z minus z_0 has a single singularity at z_0 and fz itself has no singularity anywhere. So, this rest of the function fz by z minus z_0 has a single singularity at z_0 around which we have the contour. So, evaluating the function at z_0 function F at z_0 will give us the integral of this that is a direct application that is if a function gz is analytic on the contour and in the enclosed region then Cauchy's theorem implies its integral to be 0 on the hand if the contour encloses its singularity then Cauchy's theorem does not give us a result, but then if gz is has a singularity at z_0 , but it is removed by multiplying with z minus z_0 that is if fz like this is analytic then this formula Cauchy's formula supplies a non 0 contribution to that integral around that particular point.

So, this is the purpose of evaluating the contour integral now if it happens that we do not know the function value at the interior points, but we know the function value the boundary points if that is the situation, then the same formula can be used for the reverse purpose and that is the solution of boundary value problems that is evaluation of function at an interior point if finding the interior if finding the integral on the left hand side is relatively simple then we can use the same formula to evaluate fz ; $fz 0$ that is if the function is easy to integrate over a contour and because its value over the boundary points is known and in the integer point we want to evaluate the function then this same integral formula can be used to develop this integral divided by $2\pi i$ and that gives the function value at the integer point $z 0$ this is the application of this integral formula for solving boundary value problems. So, this is for example, in the previous lecture we discussed this integral formula Poisson's integral formula which is this now we can develop this formula; now say we take the boundary point as capital R ϕ in this manner z and the integer point $z 0$ as this small r θ .

Integrals in the Complex Plane

Cauchy's Integral Formula

Line Integral
Cauchy's Integral Theorem
Cauchy's Integral Formula

Poisson's integral formula

Taking $z_0 = re^{i\theta}$ and $z = Re^{j\phi}$ (with $r < R$) in Cauchy's formula,

$$2\pi i f(re^{i\theta}) = \int_0^{2\pi} \frac{f(Re^{j\phi})}{Re^{j\phi} - re^{i\theta}} (iRe^{j\phi}) d\phi.$$

How to get rid of imaginary quantities from the expression?
Develop a complement. With $\frac{R^2}{r} e^{i\theta}$ in place of r ,

$$0 = \int_0^{2\pi} \frac{f(Re^{j\phi})}{Re^{j\phi} - \frac{R^2}{r} e^{i\theta}} (iRe^{j\phi}) d\phi = \int_0^{2\pi} \frac{f(Re^{j\phi})}{re^{-i\theta} - Re^{-j\phi}} (ire^{-i\theta}) d\phi.$$

Subtracting,

$$\begin{aligned} 2\pi i f(re^{i\theta}) &= i \int_0^{2\pi} f(Re^{j\phi}) \left[\frac{Re^{j\phi}}{Re^{j\phi} - re^{i\theta}} + \frac{re^{-i\theta}}{Re^{-j\phi} - re^{-i\theta}} \right] d\phi \\ &= i \int_0^{2\pi} \frac{(R^2 - r^2)f(Re^{j\phi})}{(Re^{j\phi} - re^{i\theta})(Re^{-j\phi} - re^{-i\theta})} d\phi \\ &\Rightarrow f(re^{i\theta}) = \frac{1}{2\pi} \int_0^{2\pi} \frac{(R^2 - r^2)f(Re^{j\phi})}{R^2 - 2Rr \cos(\theta - \phi) + r^2} d\phi. \end{aligned}$$

We want the values at $z 0$ integer point and we can easily find the value of the function on the boundary points. So, capital R is larger than small r small r is integer point. So, if we put it in the Cauchy's formula then we get $2\pi i$ if $z 0$ is equal to integral over the circle and; that means, 0 to 2π off π that is the boundary; boundary integral and this if fz by z minus $z 0$ and this whole thing is actually dz , right. So, if z is this then we will get dz as this and through this substitution through this change of variable this ϕ will vary

from 0 to 2π and now this if we try to substitute everything directly and simplify a lot of imaginary terms will remain.

So, to get rid of that what we can do is that we can consider a complimentary term; so, in place of small r if we put capital R square by r then you see here and here we put that small r in case of small r we put capital R square by r and in that case if small r is inside smaller than capital R then this will be larger than capital R right and that will mean that the corresponding point this will be outside this contour where the function is anyway analytic and therefore, the line integral will be the contour integral will be 0.

So, for that 0 is equal to 0 to 2π the same thing in place of small r if we write capital R square by r , then we will be talking about the contour integral around the point which is actually outside. So, that integral is 0 and now throughout the simplification what has been done in this simplification small r has been multiplied. So, this small r has gone it has appeared here and this small r will be appearing here this capital R has been cancelled with this r here. So, $1/r$ will vanish from here the other one r will go from here the capital R will remain e to the power $i\phi$ and e to the power $i\theta$ with these 2 factors we are dividing it. So, e to the power $i\phi$ will go up e to the power minus $i\theta$ will remain. So, in the denominator in the numerator that will happen in the denominator e to the power $i\phi$ will vanish here e to the power minus $i\theta$ will come and the reverse will happen here right. So, we get this.

Now, as we subtract this from here in a left side 0 is subtracted. So, the same thing remains on this side; however, a lot of things happen first of all this is common. So, this remains and this i is common here as well as here. So, this i goes outside that will also remains and other than that what will remain this $r e$ to the power $i\phi$ by this and this small $r e$ to the power minus $i\theta$ divided by this. So, this is positive powers this is negative powers everywhere now as we simplify this then we will find that those terms which would give imaginary parts they will cancel out and we get this result through simplification and in the denominator as we multiply out we get this and this is exactly what we studied in the what we saw in the Poisson's integral formula earlier.

So, this is F of z that is $u + iv$ is equal to this; this same $u + iv$ over the boundary points are here. So, at the interior point the function gets its value through the integral over boundary points integrated from 0 to 2π this gives us the Poisson's integral

formula for a disc and if we take the real and imaginary parts separately say writing only for real part then we will get the corresponding u is equal to 1 by 2 pi this integral everywhere the same thing here that function u will come over the boundary points. So, this establishes the Poisson's integral formula this is just an example for the unit disc for the disc as the domain, but for other such domains also this kind of formulas for solution of boundary problems can be established.

Cauchy's Integral Formula

Line Integral
Cauchy's Integral Theorem
Cauchy's Integral Formula

Cauchy's integral formula evaluates contour integral of $g(z)$,
if the contour encloses a point z_0 where $g(z)$ is
non-analytic but $g(z)(z - z_0)$ is analytic.

If $g(z)(z - z_0)$ is also non-analytic, but $g(z)(z - z_0)^2$ is analytic?

$$f(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{z - z_0} dz,$$

$$f'(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^2} dz,$$

$$f''(z_0) = \frac{2!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^3} dz,$$

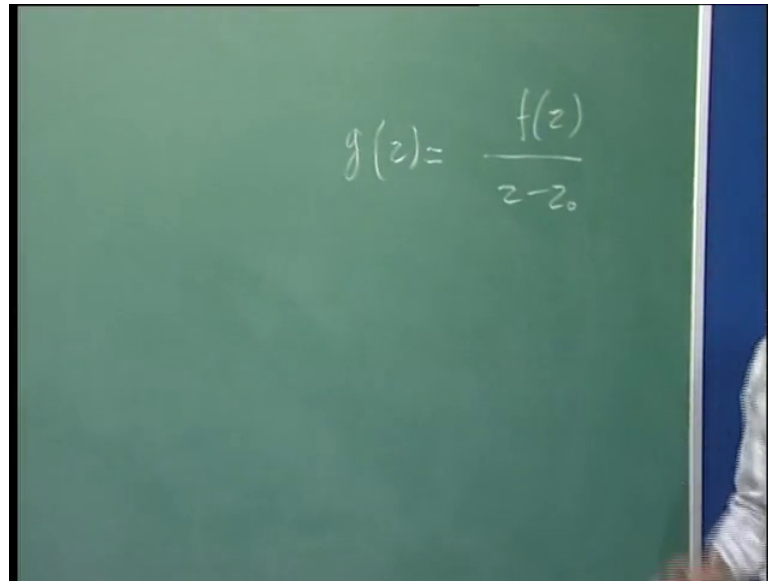

$$\dots = \dots \dots \dots$$

$$f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz.$$

The formal expressions can be established through differentiation under the integral sign.

Now, another important aspect in the evaluation of integrals is this, you know we have already discussed that Cauchy's integral formula evaluates contour integral of $g(z)$ if the contour encloses a point z_0 where the function $g(z)$ is non analytic, but $g(z)(z - z_0)$ is analytic that is one multiplication with $z - z_0$ makes it analytic in that case we get the integral evaluation through Cauchy's integral formula that is if $g(z)(z - z_0)$ is analytic then $g(z)$.

(Refer Slide Time: 49:56)

$$g(z) = \frac{f(z)}{z-z_0}$$

Turns out to be an analytic function divided by z minus z_0 an integral of such a function is given by the Cauchy's integral formula, but then if it happens that even this is analytic, but to make it analytic another multiplication of z minus z_0 is required then what to do through further processing over Cauchy's integral formula we can find a way for that also. So, this is the Cauchy's integral formula that we have discussed earlier now if we try to differentiate this expression with respect to z_0 , then we get F' prime z_0 and the these for these formal expression can be found by differentiating under the integral sign noting that z_0 and z are 2 different variables z is a boundary variable and z_0 is an integer variable.

So, if we differentiate with respect to z_0 and that is independent of z then differentiation under the integral sign will proceed directly and that differentiation and integration order can be change. So, the derivative of this will be the integral of the derivative of the integrand with respect to z_0 and with respect to z_0 differentiating this is easy because we get fz into 1 by z minus z_0 square negative and another negative sign will come because of this and. So, 2 negatives will cancel and we will get this the further derivative also appear as minus 2 fz by z minus z_0 to the power 3 into minus 1. So, minus minus again will cancel that 2 will appear and this power will get raised to 3 and so on; we can go on differentiating this the expressions of these derivatives can be established simply by differentiation under the integral sign now the actual rigorous establishment that this

really happens will require a an exercise similar what we earlier conducted to establish the analyticity of the integral of fz.

Integrals in the Complex Plane

Line Integral
Cauchy's Integral Theorem
Cauchy's Integral Formula

Cauchy's Integral Formula

$$\begin{aligned} \frac{f(z_0 + \delta z) - f(z_0)}{\delta z} &= \frac{1}{2\pi i \delta z} \oint_C f(z) \left[\frac{1}{z - z_0 - \delta z} - \frac{1}{z - z_0} \right] dz \\ &= \frac{1}{2\pi i} \oint_C \frac{f(z) dz}{(z - z_0 - \delta z)(z - z_0)} \\ &= \frac{1}{2\pi i} \oint_C \frac{f(z) dz}{(z - z_0)^2} + \frac{1}{2\pi i} \oint_C f(z) \left[\frac{1}{(z - z_0 - \delta z)(z - z_0)} - \frac{1}{(z - z_0)^2} \right] dz \\ &= \frac{1}{2\pi i} \oint_C \frac{f(z) dz}{(z - z_0)^2} + \frac{1}{2\pi i} \delta z \oint_C \frac{f(z) dz}{(z - z_0 - \delta z)(z - z_0)^2} \quad \circlearrowright \\ \text{If } |f(z)| < M \text{ on } C, L \text{ is path length and } d_0 = \min |z - z_0|. \\ \left| \delta z \oint_C \frac{f(z) dz}{(z - z_0 - \delta z)(z - z_0)^2} \right| &< \frac{ML|\delta z|}{d_0^2(d_0 - |\delta z|)} \rightarrow 0 \text{ as } \delta z \rightarrow 0. \end{aligned}$$

An analytic function possesses derivatives of all orders at every point in its domain.

Analyticity implies much more than mere differentiability!

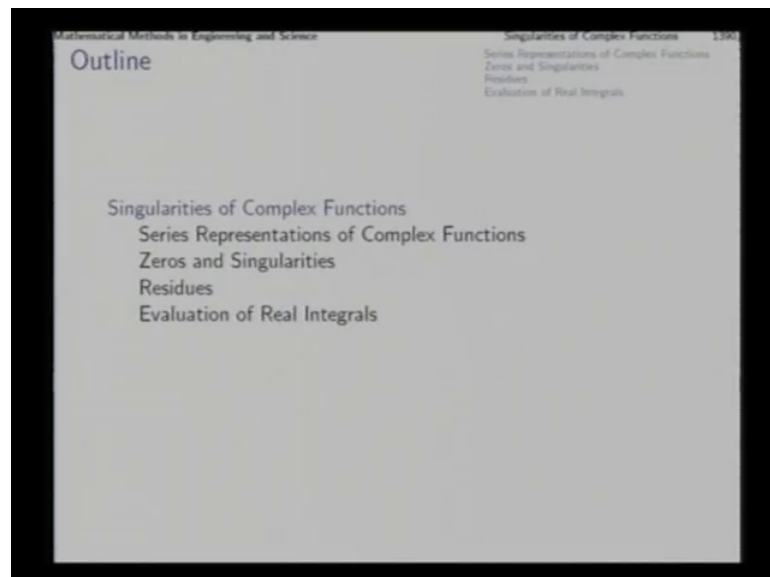

In a similar manner we could consider this to establish the this derivative to establish this derivative we need to consider an expression like this and through several simplifying steps in which we will try to separate out this part and whatever is the difference we will try to expand that and then use appropriate considerations to show that this tends to 0 as we do that finally, through the application of ml inequality we will be able to show that this part vanishes in the limit and that will show that this really tends to this and this is this is this tends to this value as delta z tends to 0 and that will mean that this turns out to be the derivative of fz 0 that is F prime z 0 and if this we can do the detailed derivation you can consult from the textbook.

Then if this part is established then by a similar exercise over this function we will be always able to evaluate this, this, this and so and this shows that and analytic function processes derivatives of all orders at every point it is domain and this is the great property of analyticity that we discussed in the previous example the analyticity is implies much more than mere differentiability it implies differentiability up to any order desired now with this established if gz is non analytic at a point z z 0, but then gz z minus z 0 to the power anything 3, 4, 5, 6, n turns out to be analytic then for that n what we do is now say for n plus 1 say for n plus 1 it is analytic then what we can do we can

we use this and then the $g(z)$ is expressed as that analytic function $g(z)$ into $z - z_0$ to the power $n + 1$ which is $f(z)$ and then this integrand becomes $g(z)$. So, integral of $g(z)$ will turn out to be $2\pi i$ the n th derivative evaluated at z_0 divided by factor of $n!$.

So, that way if as long as $z - z_0$ multiplied a finite number of times makes the function analytic then through the use of some suitable derivative formula in this series we can evaluate the contour integral of $g(z)$ and this is the great property which will be used in our next lecture also which will be a complete which will completely stress on the singularities of complex functions.

(Refer Slide Time: 55:15)

So, we use the results that we have found in this lecture into the study of singularities of complex functions in the next lecture.

Thank you.
