Forced Vibration of Two Degrees of Freedom Systems; Tuned Vibration Absorber

So we continue our discussion on free vibration of a two degree of freedom systems of course without damping. Now, I hope you remember that we mentioned that under certain very specific initial conditions a system may vibrate in a particular natural mode, where each and every member executes simple harmonic motions with same frequency. However, if the initial conditions are not chosen in that particular specific manner then the general free vibrations what results from an arbitrary initial disturbance can be expressed in terms of the natural mode of oscillations in the following way.

(Refer Slide Time: 01:18)

x_1 (Refer Slide Time: 01: 22) We also know that the ratio of the amplitude in a particular mode we have determined from free vibration analysis (Refer Slide Time: 03: 01). So, what actually remains to be done is in the four unknown quantities it is actually not like as it appears to be, because I can always expect the terms of x_2 as λ_1 into X_1 and

this should be λ_2 into X_2 . So, there will be actually only four unknown quantities that will be X_1 , X_2 , ϕ_1 , and ϕ_2 . So, these four quantities can be determined from the initial condition.

Let us solve a problem to demonstrate this. (Refer Slide Time: 03:49) Let us take a particular case of torsional oscillation (Refer Slide Time: 03:54). We call this preferably J_1 , the moment of inertia of this is J , (Refer Slide Time: 04:42) this is $2J$ and the torsional stiffness of this part of the shaft is capital K ; same is the case with this one if they are two identical shafts. The displacements are denoted by two angular rotations, (Refer Slide Time: 05:05) one for this which is called θ_1 , and one for this which is called θ_2 . Now, the initial condition is started or the oscillation is started at t is equal to 0, $\dot{\theta}_1$ at 0 equal to $\dot{\theta}_2$ at 0, θ_1 at 0 equal to θ_2 at 0, they are all 0. Only thing what we do is, we keep everything as it is only and rotate this (Refer Slide Time: 05:46). That means, θ_1 at 0 is say some angle ϕ .

So, how we have started the vibration? We have provided no velocity and we have kept this where in its original position, θ_2 equal to 0; only twisted by an amount ϕ and then, release the whole thing to execute free oscillation. Therefore, we have to find out $\theta_1(t)$, $\theta_2(t)$ and we know in general that when it is done arbitrarily, they will be composed of both the modes as shown here (Refer Slide Time: 06:38). Now, before we solve a few vibration problems, it is obviously essential to find out the natural mode oscillation.

(Refer Slide Time: 06:49)

Analysis of natural mode oscillation

$$J\ddot{\theta}_1 + K(\theta_1 - \theta_2) = 0$$

$$2J\ddot{\theta}_2 + K\theta_2 - K(\theta_1 - \theta_2) = 0$$

or, $J\ddot{\theta}_1 + K\theta_1 - K\theta_2 = 0$

$$2J\ddot{\theta}_2 + 2K\theta_2 - K\theta_1 = 0$$

For n.m. oscillation

$$\theta_1 = \theta_2 = \cos(\omega t)$$

$$\omega^2 J\theta_1 + K\theta_1 - K\theta_2 = 0$$

$$\omega^2 2J\theta_2 + 2K\theta_2 - K\theta_1 = 0$$

$$(J - \omega^2 J)\theta_1 - K\theta_2 = 0$$

$$-K\theta_1 + (2J - \omega^2 2J)\theta_2 = 0$$

Soln is possible if

$$\begin{vmatrix} J - \omega^2 J & -K \\ -K & 2J - \omega^2 2J \end{vmatrix} = 0$$

$$J(1 - \omega^2) - K^2 = 0$$

$$J(1 - \omega^2) = K^2$$

$$\omega^2 = \frac{1 \pm \sqrt{1 - 4K^2/J}}{2}$$

$$\omega_1 = \frac{1}{2} \left(1 + \sqrt{1 - 4K^2/J} \right), \omega_2 = \frac{1}{2} \left(1 - \sqrt{1 - 4K^2/J} \right)$$

First, let us do that. Now, what will be the equations of motion? However, the twist of this shaft is always θ_1 minus θ_2 . Therefore, for the first mass, if we denote the mass of the shaft with J into $\ddot{\theta}_1$ plus K into θ_1 minus θ_2 equal to 0; that is the equation of motion of the first disc. The equation of motion of second disc is $2J\ddot{\theta}_2$ plus $K\theta_2$ minus K into θ_1 minus θ_2 .

You can write it like this $J\ddot{\theta}_1$ plus $K\theta_1$ minus $K\theta_2$ equal to 0. This will be $2J\ddot{\theta}_2$ plus $2K\theta_2$ minus $K\theta_1$ equal to 0. So, these are the equations of motion. Since it is natural mode oscillation, we can assume that both are simple harmonic functions of time and θ_1 equal to $\theta_1 \cos \omega t$ and θ_2 equal to $\theta_2 \cos \omega t$. Now, if we substitute these two in these equations, what we will get? We get minus $\omega^2 J\theta_1$ plus $K\theta_1$ minus $K\theta_2$ equal to 0. This second equation will give me minus $\omega^2 2J\theta_2$ plus $2K\theta_2$ minus $K\theta_1$ equal to 0. When we write these equations properly, what we will get? We will get K minus $\omega^2 J$ into θ_1 minus $K\theta_2$ equal to 0. This will be the second equation (Refer Slide Time: 10:53). Now, obviously, solution will be possible for θ_1 and θ_2 of the state of homogeneous equations if the determinant is 0. So, the characteristic solution is possible if $2K$ minus $\omega^2 J$ whole square minus K square equal to 0 (Refer Slide Time: 11:35).

This solution will give us the natural frequencies. What are those natural frequencies for the system? It will be $2K$ square minus 4ω square KJ plus 2ω square J square minus K square equal to 0. Otherwise, it can be written as ω square whole square into $2J$ square minus $4KJ\omega$ square plus K square equal to 0. So, ω_{n1} and ω_{n2} square will be $4KJ$ plus square root of $16K$ square J square minus $8K$ square J square divided by $4J$ square. Therefore, the two roots will become, ω_{n1} square will be K by J 1 minus 1 by root 2 and ω_{n2} square will be K by J into 1 plus 1 by root 2. So, the two natural frequencies are determined. Now, let us move onto the mode state. I have told you how to find out the mode state, use any of the equations and substitute a frequency there and find out what happens. Say, for example, let us take this (Refer Slide Time: 14:30).

(Refer Slide Time: 14:45)

Now, if we take that one, we get θ_1 by θ_2 of first mode equal to K by K minus ω_{n1} square J and for the second mode (Refer Slide Time: 15:12), which we call as λ_{11} (Refer Slide Time: 15:17) λ_{22} it will be K by K minus ω_{n2} square J . Then, how much is this? We can find out, 1 by 1 minus (Refer Slide Time: 15:37) ω_{n1} square into J by K will be 1 minus 1 by root 2 and this will be equal to root 2. In this case, it will be 1 by 1 minus ω_{n1} square into J by K will be 1 plus 1 by root 2, that will be again equal to minus root 2. So, the mode states are also determined. Once the

mode states and the natural frequencies are determined, we can now use these expressions (Refer Slide Time: 16:21) or this type of representation for our ultimate final result.

(Refer Slide Time: 16:35)

$$x_1(t) = \lambda_1 \theta_1^{(0)} \cos(\omega_1 t + \phi_1) + \lambda_2 \theta_2^{(0)} \cos(\omega_2 t + \phi_2)$$

$$x_2(t) = \theta_1^{(0)} \cos(\omega_1 t + \phi_1) + \theta_2^{(0)} \cos(\omega_2 t + \phi_2)$$

$$\frac{\theta_1^{(0)}}{\theta_2^{(0)}} = \lambda_1, \quad \frac{\theta_1^{(0)}}{\theta_2^{(0)}} = \lambda_2$$

At $t=0$, $\theta_1(0) = \theta_2(0) = 0$; $v_1(0) = \psi$

Substituting these conditions,

$$\theta_1 - \theta_2 = 0, \quad \dot{\theta}_1^{(0)} = \frac{\psi}{2\sqrt{2}}, \quad \dot{\theta}_2^{(0)} = -\frac{\psi}{2\sqrt{2}}$$

So, let us replace x by θ . Now, it is the actual vibration, not normal mode oscillation. So, this θ_1 we should not confuse with the solution of θ_1 what you are doing and the amplitudes are θ_1 and θ_2 . Similarly, here also we have used this (Refer Slide Time: 17:41). What can we do? Now, we can write this as θ_1 , which is nothing but λ_1 into θ_2 and θ_2 is nothing but λ_2 into θ_1 . Now, both these λ s and ω s are all known.

Now, what we do? We use this initial condition and we find out $\dot{\theta}_1$ and $\dot{\theta}_2$ and t is equal to 0. We substitute both as 0 then θ_2 also at t is equal to 0 and θ_1 at 0 is equal to ψ , using all these we get ϕ_1 equal to ϕ_2 equal to 0. θ_1 is equal to ψ by $2\sqrt{2}$ and θ_2 equal to minus ψ by $2\sqrt{2}$. Using these expressions, we will get $\theta_1 t$. This is the complete solution (Refer Slide Time: 21:12). Therefore, we can solve the free vibrations problems of a 2 degree of freedom system for an arbitrary initial condition.

The procedure is: first, we solved for the natural mode vibration, determined the mode state and the corresponding natural frequencies; then, used the general expression in

terms of the two natural modes. Then, using the initial conditions, we will find out the final one.

It is important for us to solve the force vibration problem of a 2 degree of freedom system. Why we are doing it? Because it is not only for the sake of completeness of the analysis of 2 degree freedom system, but also for the force vibration of 2 degree freedom system has some very important practical applications in engineering. In force vibration of 2 degree freedom systems, we now take up and we solve a particular system, though there is no problem in handling a case, but we will involve ourselves primarily with this system as it has considerable amount of practical applications.

(Refer Slide Time: 22:30)

So, our system is quite simple. It is $k_1 m_1$ and then, this is $k_2 m_2$ and this system is again connected with m_1 . There is a simple harmonic force applied to this mass m . What will be the solution? Now, one thing we should all the time remember that in the steady state solution of a force vibration problem, even though there is no damping associated but in nature everything ultimately gets damped. So, in the steady state, we will have solution of the system in a way that everything vibrates with the same frequency. Therefore, we can always assume the steady solution of a force vibration problem as again another simple harmonic function of time, with the same frequency.

The pivoted diagrams if you want to draw, in this direction (Refer Slide Time: 24:47) the state of the spring here is x_2 minus x_1 . It will be k_2 into x_2 minus x_1 acting in this direction. This is externally applied force. Of course, the force is equal and opposite of this. So, the equation of motion in this direction is $m_1 \ddot{x}_1$ and this must be equal to total force in this direction is $F_0 \cos \omega t$ plus k_2 into x_1 minus x_2 minus $k_1 x_1$. There is one opposite force, which is minus $k_1 x_1$. For mass, two total force in that direction is minus k_2 into x_2 minus x_1 .

Now, let the steady state solution be x_1 is equal to $X_1 \cos \omega t$; x_2 is equal to $X_2 \cos \omega t$. That is the matter of the phase because we know when there is no separate damping; the phase difference between various bodies can be either in same phase or in opposite phase. So, that matter is taken care of by the signs of x_1 and x_2 . If x_1 and x_2 are of the same sign, then they will be same. If they are of opposite signs, they will be (26:54). Now, substituting this in these two equations of motions, what do we get? Then if we organize this will become minus ω^2 capital X_1 and $\cos \omega t$ everywhere will ultimately get cancelled.

(Refer Slide Time: 27:18)

Handwritten derivation of the steady-state solution for a two-mass spring system. The diagram shows two masses, m_1 and m_2 , connected by a spring with constant k_2 . Mass m_1 is also connected to a wall by a spring with constant k_1 . An external force $F_0 \cos \omega t$ is applied to mass m_1 . The displacement of mass m_1 is x_1 and the displacement of mass m_2 is x_2 .

The equations of motion are:

$$(k_1 + k_2 - m_1 \omega^2) X_1 - k_2 X_2 = F_0$$

$$-k_2 X_1 + (k_2 - m_2 \omega^2) X_2 = 0$$

Solving for X_2 :

$$X_2 = \frac{k_2}{k_2 - m_2 \omega^2} X_1$$

Using this in the first equation:

$$\left[(k_1 + k_2 - m_1 \omega^2) - \frac{k_2^2}{k_2 - m_2 \omega^2} \right] X_1 = F_0$$

Solving for X_1 :

$$X_1 = \frac{F_0 (k_2 - m_2 \omega^2)}{(k_1 + k_2 - m_1 \omega^2)(k_2 - m_2 \omega^2) - k_2^2}$$

And the steady-state solution for x_2 is:

$$x_2 = X_2 \cos \omega t$$

So, we can write directly as k_1 plus k_2 minus $m_1 \omega^2$ X_1 minus $k_2 X_2$ is equal to F_0 . The second equation will become minus $k_2 X_1$ plus k_2 minus $m_2 \omega^2$ into X_2

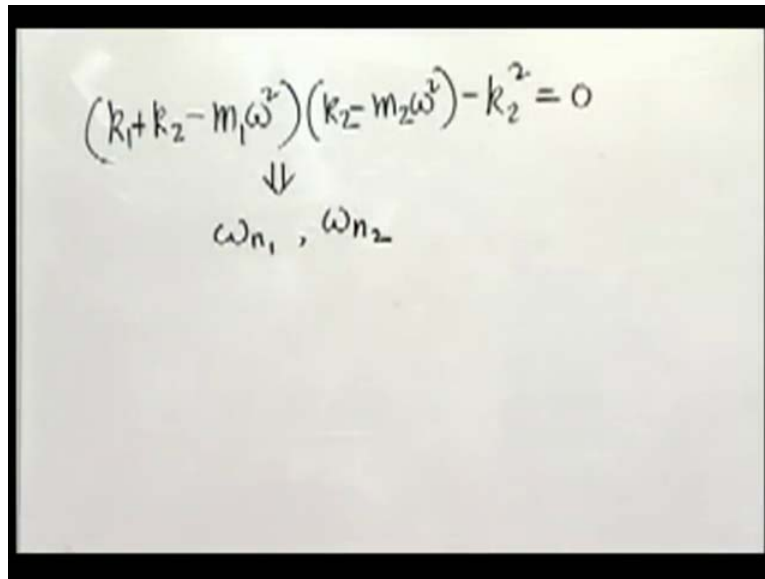

equal to 0. Therefore, there are two equations and only 2 unknown X_1 and X_2 , because, you know in all forced vibration problems, our objective is to find out the magnitude of vibration. Frequency is already known, which is equal to the force into frequency. In free vibration, our final objective is to find out the sequence and the amplitude depends on the initial disturbance given. To solve it, let us express X_2 in terms of X_1 , so X_2 is k_2 by k_2 minus m_2 omega square into X_1 . Substituting this in the equation (Refer Slide Time: 29:15) we get X_1 equal to F_0 into k_2 minus m_2 omega square divided by k_1 plus k_2 minus m_2 omega square into k_2 minus m_2 omega square minus k_2 square.

(Refer Slide Time: 30:30)

$(k_1 + k_2 - m_1 \omega^2)X_1 - k_2 X_2 = 0$
 $-k_2 X_1 + (k_2 - m_2 \omega^2)X_2 = F_0 \cos(\omega t)$
 $X_2 = \frac{k_1}{k_2 - m_2 \omega^2} X_1$
 Using this
 $\left[(k_1 + k_2 - m_1 \omega^2) - \frac{k_2^2}{k_2 - m_2 \omega^2} \right] X_1 = F_0$
 $\therefore X_1 = \frac{F_0 (k_2 - m_2 \omega^2)}{(k_1 + k_2 - m_1 \omega^2)(k_2 - m_2 \omega^2) - k_2^2}$
 $X_2 = \frac{F_0 k_1}{(k_1 + k_2 - m_1 \omega^2)(k_2 - m_2 \omega^2) - k_2^2}$

Using this, if we multiply this quantity by this, X_2 will become like this (Refer Slide Time: 30:45). Now, here one thing is very clear, both X_1 and X_2 become infinite when the denominator becomes 0.

(Refer Slide Time: 31:15)

$$(k_1 + k_2 - m_1 \omega^2)(k_2 - m_2 \omega^2) - k_2^2 = 0$$
$$\Downarrow$$
$$\omega_{n_1}, \omega_{n_2}$$

The denominator becomes 0, that is, the solution of this equation will lead to two values of omega. Now, remember this omega is not the total frequency. I am saying at which this becomes 0. So, obviously, this will give two frequencies. One will be the first natural frequency and the other will be second natural frequency. Therefore, this will be 0, when the exciting frequency omega matches one of the two natural frequencies of this system when it is allowed to vibrate freely. The solution to this ω_{n_1} and ω_{n_2} can be found out from this characteristic equation we can find that for the few vibration problems, F_0 is 0 and so, the two equations which we get here both are homogeneous and their solution will exist only when its determinant is 0, which is again nothing but this (Refer Slide Time: 32:32).

(Refer Slide Time: 32:38)

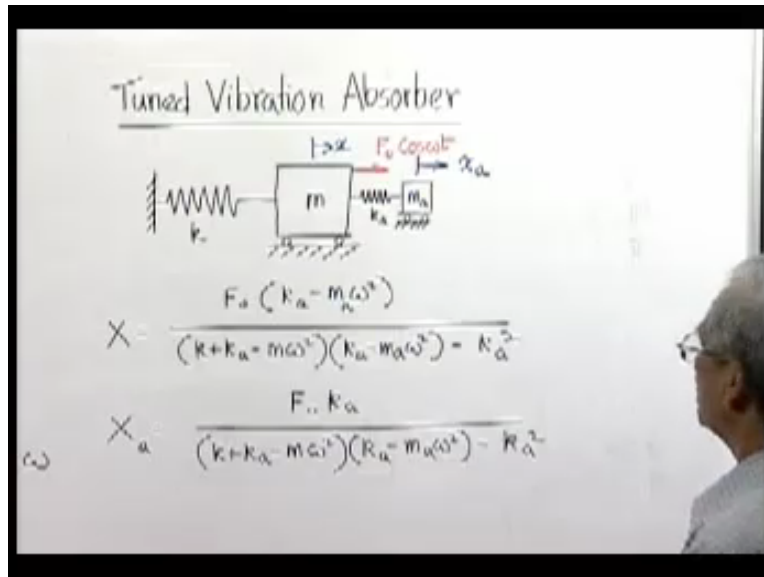

If we plot, let this be ω_{n1} , this be ω_{n2} is equal, and this will be 0. The vertical axis we will have two, one is X_1 and the other is X_2 . Now, when ω is 0, X_1 is equal to 0. So, ω is 0, top one will be F_0 into k_2 and the bottom will be k_1 into k_2 . k_2 square will get cancelled; so, only k_1 into k_2 . So, the total thing will be F_0 by k_1 . It starts with F_0 by k_1 . Then it increases as this ω tends to ω_{n1} and this denominator tends to be 0. So, as ω tends to ω_{n1} , this tends to be like this (Refer Slide Time: 34:42). Then, when ω crosses ω_{n1} , then it starts and it becomes negative. Again, it becomes smaller and it becomes 0, when ω is equal to square root of k_2 by m , again it becomes positive. When ω crosses ω_{n2} , we can show that this is the nature of function X_1 , when you plot against ω .

If you plot X_2 , what we get? When ω is 0, obviously, this is 0, this is 0, k_2 square gets cancelled. So it starts from the same point but again it goes up, but when this crosses 0, then we will find that it can be shown like this (Refer Slide Time: 36:18).

So, this is the nature of variation of (36:20) (Refer Slide Time: 36:24). When at this position, ω^2 is equal to k_2 by M , this term is 0. So, X_2 in that condition will be minus F_0 by k_2 . So, and this much will be minus F_0 by k_2 . Now, the important thing to note is that for a particular situation, when exciting sequence is equal to square root of k_2

by m_2 , then the primary mass m_1 stops vibrating. When this stops vibrating (Refer Slide Time: 37:40), we can use these techniques for stopping vibration in system by attaching an auxiliary mass and this is called vibration absorber.

(Refer Slide Time: 37:54)

In vibration absorber, this is the primary system or system which is the real system and it is being subjected to simple harmonic excitation. Then we want to stop this vibration, because it is obviously going to vibrate, the technique is then to attach a separate system which we call the absorber system. Obviously, the absorber vibration is x_a . So, the same equations apply; our amplitude of vibration X under this condition will be F_0 into k_a minus m omega square by k plus k_a minus m omega square into k_a minus m_a omega square minus k_a square (Refer Slide Time: 40:22). So, this is the amplitude of the primary mass oscillation and this is the amplitude of the absorber mass oscillation (Refer Slide Time: 40:40). Since our objective is to absorb or stop the vibration, we should always tune it in such a manner, so far as the vibration absorber is concerned that the exciting frequency is equal to k_a by m_a from there, because under that condition, this will be 0.

The primary mass vibration stops. Also, generally since the vibration of a system is more problematic when it resonates, therefore, we have to be careful about those situations, where omega is equal to the natural frequency of the primary system.

(Refer Slide Time: 41:30)

Therefore, generally the tuning is done in this manner. The natural frequency of the system is equal to natural frequency of the absorber, omega should also match this. Then, we will get the best results that this package vibration force is there and the system is trying to resonate, then we attach an absorber mass and the vibration stops. Now, why it stops can be easily seen. What happens when force is equal to or omega is equal to square root of K_a by m_a ?

When omega is equal to square root of k_a by m_a , we find that X is equal to 0. How much is X_a now? k_a by m_a is equal to omega. So, this becomes 0; so this goes. Hence, X_a is nothing but F_0 by k_a with a minus sign.

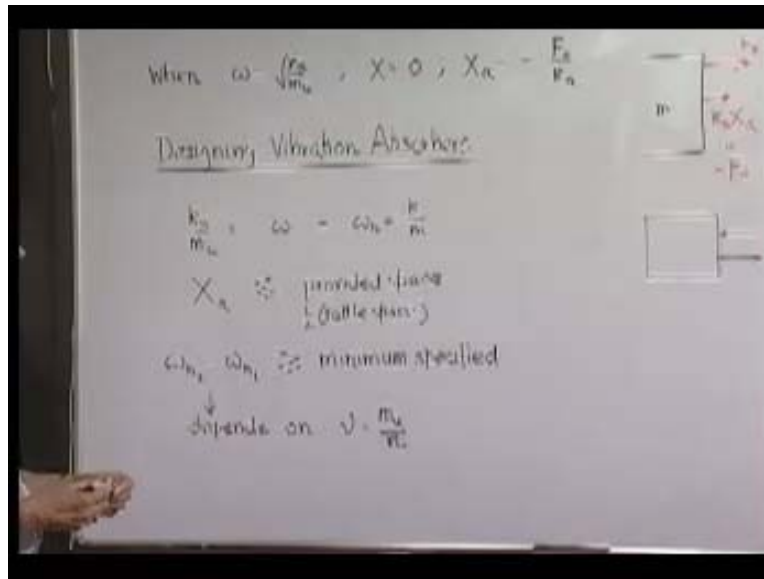

(Refer Slide Time: 43:03)

Now, what will be happening if this is the auxiliary system and this is the main system, then the force which is acting here, it will be simply k_a into X_a . Of course, there is another force here, which is F_0 . Now, how much is this under this tuned condition? It is minus F_0 plus every instant of course when you multiply by cosine omega t in both the places, what happens?

When this primary mass is subjected to two forces, one is $F_0 \cos \omega t$ and the other is minus $F_0 \cos \omega t$. Therefore, the sum total of the force acting on the primary mass is always pivoted at every instant. So, every time the force which is acting here is neutralized by the spring force attached due to vibration of the auxiliary system. Thus we find that the vibration of the primary mass stops at this equations, only because the vibration of the auxiliary mass produces a force on the primary mass at every instant which is equal and opposite to the externally applied shear. So, actually a better term would have been vibration neutralizer, because it really neutralizes the force in action. Since the vibration stops, people have generally always called it as vibration absorber, but there is no dissipation of energy as you can see. Therefore, designing vibration absorber is a very important thing.

(Refer Slide Time: 45:35)

When you want to design a vibration absorber, its conditions will be primarily that k_a by m_a will be equal to ω , which is known and (Refer Slide Time: 46:25) this is generally ω_{n1} of this (Refer Slide Time: 46:20) Then, we have to also be careful about it must be less than or equal to provided space or called the rattle space. If everything vibrates, the total amount of space is occupied; it will be on both sides of the initial position by an amount X_a . So, the total amount of rattle space is always twice X_a . So, X_a should be less than equal to half the rattle space provided in the system; it cannot be anything. Therefore, these are the two very important conditions. Another important condition is that what we find here that if we operate exactly at that frequency, there is no problem and X_1 is 0.

But always you know in our real system, the exciting force may fluctuate in its frequency. If it happens that rather than that your operation is here (Refer Slide Time: 47:47), then, you find that your amplitude will be this point (Refer Slide Time: 47:55), which otherwise perhaps it would have **been much less than even** without the absorber, if the force acts, sometimes it may happen that the amplitude of the system is less than what you will have with the vibration absorber, because now this one natural frequency is split into two and you are going very near to another one. Therefore, it is important that it does not happen. You would like to have as much separation or spreading out of the natural

frequencies as possible So that even if there is some fluctuation of the force in frequencies, the chances of it will be going to one of the natural frequencies after this absorber is attached []. Therefore, the other conditions will be $\omega \neq \omega_n$ the two natural frequencies emerge only because we have attached the absorber system otherwise it was a single degree freedom system should be more than equal to some minimum specification point.

The points that we have to keep in mind while designing vibration absorber: one is that its natural frequency of the absorber systems will be exactly equal to the total frequency, which normally is near the natural frequency of the system. This actually tells you what can be the maximum value of the amplitude of the absorber mass and what minimum spreading is required between the two natural frequencies of the resultant system to avoid a large oscillation in case of fluctuation in the exciting frequency. These are the three conditions. Now, this depends on as you can show on a quantity which is called μ , which is the ratio between the two masses which determine the ratio. To find out the characteristic equation, it can be solved like this.

(Refer Slide Time: 50:25)

Handwritten derivation of the characteristic equation for a vibration absorber. The text on the left side of the page reads: "oscillators", " $\frac{k}{m}$ ", "base", "(c)", and "specified". The equations shown are:

$$0; X_a = \frac{F_0}{Y}$$

$$\omega^4 - \left(\frac{k_a}{m_a} + \frac{k}{m} + \frac{k_a}{m} \right) \omega^2 + \frac{k k_a}{m m_a} = 0$$

$$\left(\frac{\omega}{\omega_n} \right)^4 - (2 + \mu) \left(\frac{\omega}{\omega_n} \right)^2 + 1 = 0$$

$$\omega / \omega_n = X$$

$$X^4 - (2 + \mu) X^2 + 1 = 0$$

Two roots are X_1, X_2

$$X_1^2 + X_2^2 = (2 + \mu)$$

$$X_1^2 X_2^2 = 1$$

So, this equation becomes ω to the power 4 minus k_a by m_a plus k by m plus k_a by m into ω square plus $k k_a$ by $m m_a$ equal to 0. If we expand, this will be the equation.

Now, we can divide the whole thing by ω_{na} to the power 4. Now, if you take k_a by m_a common, remember k_a by m_a is equal to k by m . So, there actually, it is nothing but 2 into k_a by m_a , take k_a by m_a common, which is ω_{na} square and if you divide by ω_{na} to the power 4, then below we get ω_{na} square. Therefore, we will have this one and this 2 plus, if we divide this by k by m_a , what we will get is m_a by m , which is nothing but ν and this will be (Refer Slide Time: 52:02) k_a by m_a and k by m are both equal to ω_{na} square. So, this whole thing is nothing but ω_{na} to the power 4 and when you divide by ω_{na} to the power 4 this is 1.

(Refer Slide Time: 52:02)

$$x^4 - (2+\nu)x^2 + 1 = 0$$

Two roots are x_1^2, x_2^2

$$x_1^2 + x_2^2 = (2+\nu)$$

$$x_1^2 x_2^2 = 1$$

$$x_1 x_2 = 1 \Rightarrow x_2 = \frac{1}{x_1}$$

$$x_1^2 + x_2^2 + 2x_1 x_2 = 2+\nu+2 = 4+\nu$$

$$(x_1 + x_2)^2 = 4+\nu$$

$$x_1 + x_2 = \sqrt{4+\nu}$$

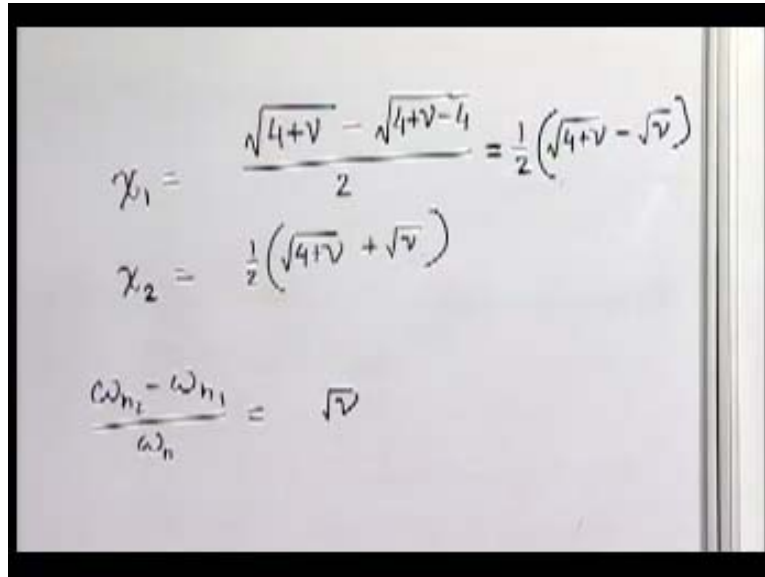

$$x_1 - \sqrt{1+\nu}x_1 + 1 = 0$$

Let us call this to be this equation: x to the power 4 into 2 plus ν into x square plus 1 equal to 0 (Refer Slide Time: 52:30). So, it will lead to two roots, which are χ_1 square and χ_2 square. So, we know from that quadratic equation, the sum of the two roots equal to minus 2 plus ν and the product of the two rows are equal to 1. Therefore, you can write χ_1 into χ_2 is obviously 1; not minus 1, because χ_1 and χ_2 are both positive.

Now, if we add χ_1 square and χ_2 square and we multiply this by 2, it becomes 2 χ_1 χ_2 . So, what we can do? We can add 2 χ_1 plus χ_2 , this is equal to 2 plus ν and this is equal to 1 plus 2 equal to 4 plus ν . This whole thing is nothing but again χ_1 plus χ_2

whole square. So, χ_1 plus χ_2 is equal to square root of 4 plus ν . This tells us that χ_2 is equal to $1/\chi_1$. If we use this here we will get χ_1 square minus 4 plus $\nu \chi_1$ plus 1 equal to 0.

(Refer Slide Time: 55:05)

The image shows three equations written on a whiteboard:

$$\chi_1 = \frac{\sqrt{4+\nu} - \sqrt{4+\nu-4}}{2} = \frac{1}{2}(\sqrt{4+\nu} - \sqrt{\nu})$$

$$\chi_2 = \frac{1}{2}(\sqrt{4+\nu} + \sqrt{\nu})$$

$$\frac{\omega_{n2} - \omega_{n1}}{\omega_n} = \sqrt{\nu}$$

Solving this, we get χ_1 equal to half into square root of 4 plus ν minus root ν and χ_2 equal to half (Refer Slide Time: 55:47) into square root of 4 plus ν plus root ν . So, ω_{n2} minus ω_{n1} divided by ω_n of the primary original system that is (56:20), so we will find this is equal to root ν . Therefore, (Refer Slide Time: 56:42) two natural frequencies between that and this is given by square root of k by m , this is a known quantity (Refer Slide Time: 56:56), which is same as ω equal to ω_n . So, it depends on this mass ratio (Refer Slide Time: 57:06).

Therefore for a given primary system, what will be the mass of the auxiliary? What will be the thickness of the auxiliary? All these two things you have to find out satisfying this condition. May be solving one example (57:24) will try to solve one problem to demonstrate how this vibration absorber is designed.
